The specific gravity readings of all cells of a battery should normally rise and fall together, as all cells of a battery as used with most systems are connected in series so that the charging and discharging current passes through all alike. (see also "cadmium tests" and pages 410, 416.)

If the hydrometer reading of one cell should be considerably lower than the readings of the other cells in the battery, and if this difference should increase from week to week, it is an indication of trouble in that cell.

The trouble may be due to a short circuit (page 456), causing the cell to discharge itself, or it may be due to a leaking jar, as a slight leak will allow electrolyte to escape, and if not noticed, the addition of water to replace its loss will lower the gravity.

A short circuited or leaking cell must be attended to at once (pages 473-456).

Thermometer used in connection with the hydrometer is very necessary as the sp. gr. readings are indicated at 70° F.; above or below this temperature the readings are not correct. See "Thermometer, its purpase," pages 447, 449, 451.

See page 457, locating battery troubles with a hydrometer, see also page 421 and 422.

**To Tell When a Battery Needs Recharging.

On systems where a storage battery is kept charged by a generator run from the engine the system is supposed to be automatic and the indications would be a **weak starting motor, or dim lights.** The battery, however, in this case ought not be allowed to become weak.

By testing with a hydrometer as per chart 204 the condition of battery can always be ascertained, and it is advisable to test at least once a week.

It will be well therefore before adding **distilled** water to the battery, to test the electrolyte with the hydrometer.

It must be borne in mind that a battery used for a starting motor is practically discharged, or so low that it will not properly operate the starter, when specific gravity is 1.225. Whereas when used only for lights or ignition, it will supply current down to 1.150 sp. gr.

As you charge your battery, the hydrometer readings will **increase** with the state or degree of charge.

As you **discharge** your battery, the readings will **diminish** with the degree of discharge.

Therefore it is advisable to recharge from an outside source or run with fewer lights, and run more in the day time with lights off, when the hydrometer reading is as low as 1.225. See chart 204.

*The Volt Meter for Testing Battery.

A battery should never be discharged completely. As stated, when testing with a hydrometer 1.150 is the limit for batteries used for ignition and lights and 1.225 for starting motors.

A volt meter can also be used to test the cells, but bear in mind the test is not practical unless it is made when battery is discharging or charging. See page 414, 416, 410, and note how meter is connected to test one or all cells.

Each cell should never show less than 1.8 volts per cell or 5.4 volts for a 6 volt battery (readings taken when battery is discharging or charging). The normal voltage of the battery is 2.2 volts per cell when doing no work, which is, if the electrolyte be 1.250 sp. gr., usually lowered to about 2.1 volts, due to internal resistance.

The storage battery unless worked below 1.8 volts, has a recuperative power of raising from 1.8 volts to the normal 2.1 or 2.2 volts within a few minutes after the discharge current has been discontinued. This act has often led many users astray as to their opinion of the condition of their cells.

For instance, suppose one to be out with his car, and the spark is not sufficiently strong to give satisfactory ignition of the gases; he stops to locate the defect. Usually the first thought is, are the batteries right? The voltmeter is taken and put to the cells and because they read 2.0 to 2.1 they are deemed all good.

Whereas, if the reading had been taken while battery was discharging, the volt meter would probably have read 1.8 volt or perhaps less per cell. In this way it often occurs, that much time has been lost in going over the car looking for the defect, while all the time it has been the batteries which have innocently showed 2.0 volts, because they were standing idle.

The voltmeter can also be used to determine the positive and negative pole of battery. Touch voltmeter terminals instantaneously across the circuit. If needle runs upward in the normal direction on the scale, voltmeter is properly connected and the wire which touches the positive meter terminal is thus identified as positive. If the connections were reversed, the needle would kick off the scale, indicating that the positive terminal of the voltmeter should be connected to the other wire. Note—never

*Note—Many repair shops have volt meters per pages 414, 416, 410. When a charged battery is discharging it will give say about 2 volts per cell until 50% of its capacity is used, then gradually drop to 1.8 volt per cell. Therefore a meter reading in one-tenth part of a volt will give accurate test if battery is on discharge, telling the condition between the 2 volt drop and 1.8 drop in fractions of a volt. See pages 416, 410, also page 864D, for "Cadmium Tests."

**Also see pages 410, 416, 414, 421 and 422.

connect an ammeter to the terminals of a battery, unless a shunt is used. See chart 191.

The specific gravity test with a hydrometer is the only safe way. Provide your self with a hydrometer to enable you to test the gravity of your electrolyte periodically, and you will avoid a great deal of trouble. (See chart 204A.)

It may be said that the condition of the specific gravity is the pulse of the cell, and certainly it is the one means of ascertaining the exact condition of health of the cell or battery.

*Care of a Storage Battery.

The care of a battery in service or where there is a generator on the car to recharge it, is summed up in the four following rules, which, if observed with reasonable care will result in the best service being obtained:

1—Add nothing but pure water to the cells and do it often enough to keep the plates covered.

2—Take frequent hydrometer readings.

3—Give the battery a special charge whenever the hydrometer readings show it to be necessary.

4—Keep the filling plugs and connections tight, and the battery clean.

Adding Water.

Water must be added often enough to keep the plates covered. If the plates are exposed for any length of time, they may be seriously damaged.

The length of time a battery can go without the addition of water will depend upon the season of the year, water being required more frequently in summer than in winter.

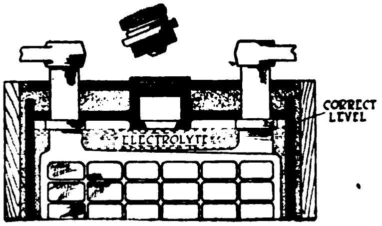

Fig. 14—Section of cell, showing correct level of electrolyte.

The best plan is to make it an invariable rule to remove the filling plugs once each week and add water if level of electrolyte is below bottom of filling tube.

Never bring an open flame, such as a match or candle, near the battery.

Always add the water regularly, though the battery may seem to work all right without it.

In freezing weather, when necessary to add water, always do it just before running the engine.

If temperature is extremely low, start the engine so that the battery is charging before adding water.

The reason for this is that water being lighter than electrolyte will remain on the surface and will freeze in cold weather. If the engine is run, however, the gassing, due to the charging current, will thoroughly mix the water with the electrolyte; also the motion of the car when running will have a similar effect. Thoroughly mixed electrolyte will not freeze solid, except at very low temperatures.

*Also see pages 421, 422, 416, 410.

The reason why the solution (electrolyte) falls below the top of the plates, is due to evaporation. Water evaporates when battery is in service, the **acid does not,** therefore it will be necessary to replace the water —but don't add too little and don't add too much. Many a case of apparent leak has been blamed to an over indulgence of water.

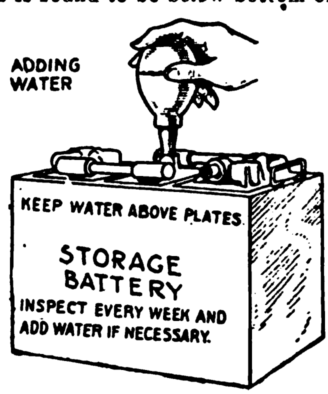
You will have to replace evaporation but do not add enough water to any cell to raise the electrolyte above the indicated level.

Electrolyte level. Note that for each battery there is a well defined level, up to, or nearly to which, you should endeavor to keep the surface of your electrolyte, but above which you must never raise the level of the solution when you add water to your battery. In the U. S. L. type EDC battery as an example, the level is 1 inch above plate tops. In the type EL the level is ⅝ inch. In all other types of U. S. L. batteries the electrolyte level is ½ inch above the plates.

Not only should the electrolyte level be at the same height in all cells, **but there should be the same amount of acid in the electrolyte in each cell. Therefore always** restore the electrolyte from syringe when testing, back into cell from which it was taken.

Each time water is added to the cells, first take a hydrometer reading of each cell to see whether all cells are equally healthy. No cell can live unto itself—if it goes wrong it affects the others.

How to add water: Remove filling plugs by turning to the left, and if level of electrolyte is found to be below bottom of filling



tube (fig. 1, chart 203A), add water by means of the hydrometer syringe or a very small pitcher until the level begins to rise in the tube.

After adding water be sure to replace filling plugs and tighten by turning to the right. **If filling plugs are not tightened, the electrolyte will flood out of the battery and cause damage.** Also wipe off the top of battery.

****Kind of water:** The water used must be of reasonable purity, as the use of impure water, if persisted in, will injure the plates. Distilled water, melted artificial ice, or rain water collected in clean receptacles is recommended.

Water collected in rain barrels from metal roofs, would contain a trace of the mineral —therefore avoid same.

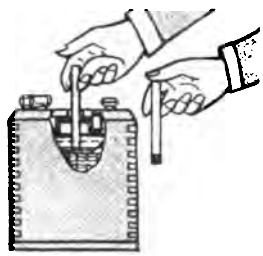
Nothing but pure water must be put into the cells. If acid of any kind, alcohol, or in fact anything but water, is added to the cells, it will result in very serious injury to the plates and may ruin them.

There being no loss of acid, it is never necessary during normal service, to add any acid to a battery.

If electrolyte has been spilled from the battery by accident, the loss may be replaced with electrolyte, see page 473.

Finding Level of Electrolyte.

Unscrew the vent from its well, push a glass tube with both ends open, straight down, as shown above, through the



well and against the tops of the plates. Then close top end of tube with your thumb and remove the tube with the top end still closed. The height of liquid in the tube equals the height of the electrolyte level above the tops of the plates. Be sure to restore the electrolyte to the cell from which it was taken. If you persistently take electrolyte from one cell and put it into another you will gradually get your cells unbalanced. Be sure to test levels in all cells.

Take frequent hydrometer readings, for they show whether the battery is receiving sufficient charge.

When the battery is used in connection with a charging generator system, the system is so designed and adjusted that the amount of charging current received by the battery from the charging generator (dynamo) should about compensate for the discharge current used when starting the engine or when lighting the lamps from the battery. At medium or high speeds, the current for lamps does not come from the battery, but from the dynamo.

It sometimes happens, due to unusual conditions, such as excessive use of lamps, especially when car is driven at low speed, that the battery will not receive enough charge from the dynamo and will become more or less discharged, which will be indicated by lowered hydrometer readings (pages 421 and 422).

When battery is used alone (without generator), the hydrometer readings will likewise indicate the state of discharge of the battery and when it is necessary for it to be charged.

*Care of Battery With a Generator on the Car.

Care of battery case: If water or electrolyte is spilled upon the battery or in the compartment, wipe dry with waste. If electrolyte is present in any quantity, use waste moistened with weak ammonia in order to neutralize the acid in the electrolyte. Do not allow electrolyte to collect upon the woodwork as it will cause deterioration.

Once a week, when adding water, inspect all the battery connections and make sure that they are tight and clean. **A loose or dirty connection** may cause trouble when least expected.

Care of connections: If signs of corrosion of any brass or copper parts should appear, clean the parts thoroughly with weak ammonia and apply vaseline.

Connections throughout the system must be examined periodically and kept tight and clean. Sometimes a connection even if tight, will give trouble, due to foreign matter such as paint or varnish on the contact surfaces. This must be removed with a file or sand paper. **The connections to the generator and the grounding connections to the frame of the car must not be neglected.**

*Care of Battery Without a Generator on the Car.

If the battery is used alone (without generator) to supply current for lights or ignition, it will not be necessary to add water except when the battery is removed from the car for charging.

Frequent hydrometer readings should be taken, however, and when the gravity falls below 1.200, the battery should be removed from the car and charged.

Do not allow the battery to discharge until completely exhausted, as shown by gravity falling to 1.150 or thereabout and by lamps burning dimly or voltage falling below 1.8 volts per cell.

Give the battery a charge at least once every two months whether the hydrometer readings show this to be necessary or not.

Battery Out of Service.

If the battery is not to be used for a considerable period, say the winter months or longer, it should be taken where it can be charged once every month and the plates kept covered by regularly adding **distilled** water. If charging is not possible, do not attempt to remove the electrolyte, but send the battery to the nearest place which has facilities for the periodic charge.

If this cannot be done, add distilled water to each cell until solution reaches inside cover, then charge to full voltage and store in a dry place. Inspect battery, once a month, refill with pure distilled water to make up for evaporation and give it a refreshing charge at the finish rate.

It should be fully recharged before storing; also recharged when put into service again. Another point, **don't forget to disconnect battery wires,** if left standing for a long period of time, in order to not lose its charge through a slight leak.

If batteries are to be idle for a continued long period—fully charge, then remove electrolyte and put in distilled water.

When battery is put into use again remove water, put in 1.300 sp. gr. electrolyte and recharge. Just as soon as the electrolyte is put into battery under these conditions the plates will absorb the acid from the solution and will drop in sp. gr. to as low as 1.100 but just as soon as battery is put on charge and fully charged it will rise to 1.300.

*See also pages 456, 458 and 422. **See also foot note page 458. See also, page 709 how to make a **home-made still.**

INSTRUCTION No. 32-A.

*STORAGE BATTERY TROUBLES AND REPAIRS:

Troubles; their cause and how to locate them. Repairing. Charging Rate and how to Charge a Storage Battery. Resistance; Lamps and Units. Rectifiers; Mercury Arc and Chemical. Battery Repairman's Outfit. Lead Burning. The Edison Storage Battery.

Miscellaneous Troubles.

Fig. 1. Sulphated plate.

The storage battery must be properly cared for; if neglected, after a few months use it will not give satisfaction.

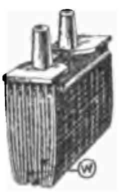
†Sulphating of plates means that a white chalky substance forms on the negative plate which is a non-conductor and insoluble. The positive plate can be remedied by charging, but not so with a negative plate, if too far gone. A battery expert can sometimes remedy same, by long continued charging at a low rate.

The cause of sulphated plates is usually due to lack of water kept over their tops, or battery left standing for a long time without charging. Also from sediment.

Keep water above the plate tops, see to it that charging is not neglected, and that there is no discharge caused by short-circuits within or without the battery, and you will have no sulphation.

If yours is a "double voltage" system, see to it that the distribution of charging current is equalized. See page 466.

***Keep battery terminals clean:** Always have a solution of common baking soda and water handy for cleaning the battery terminals; also vaseline for applying to battery connections after cleaning to prevent the acid from again corroding the connections.



Arrow points (W) show how broken down wood separators allow plate to bend and touch causing a short circuit of plates.

Also keep battery terminals **tight**—this is very important.

Battery short-circuits. Battery short-circuits may be internal, or external.

If they are internal, the battery itself may be worn out, the plates warped or buckled, or a collection of sediment at the bottom of cells due to disintegrating plates, although the latter is rare because of the height of the plates above bottom of jar.

External battery short-circuits may be due to acid on the top of the battery forming an electrolyte between terminals; battery terminals sulphated, or in contact with top of metal battery box, or battery wire connections acid soaked.

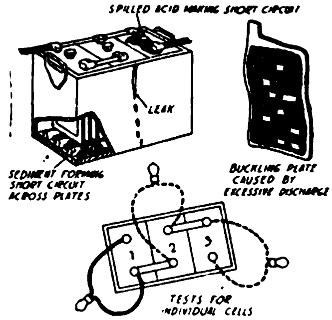


Fig. 2. Common battery troubles and a simple test.

Sediment—any impurities that the water contains is left behind in the cells by the evaporation of the water.

Mud and sediment will accumulate in the bottom of the battery and will eventually short circuit the plates, if any other than distilled water is used. The paste falling off the plates will also result in sediment collecting. When cleaning the sediment from a jar, the separators are usually replaced at the same time. The need for cleaning is usually indicated by lack of capacity, excessive evaporation of the electrolyte and excessive heating when charging.

Buckling or warping of plates: There is a tendency for the plates to shed the paste after it hardens on the grid, called "buckling" of the plates, meaning to distort, or get crooked, from sudden high discharges. Other causes, will often cause the active material (paste) to loosen and fall out of the grids, and go to the bottom of the jar and cause a "short-circuit" from one plate to another.

Some of the causes are: dead short circuit, as between starting motor and battery; overcharging by boiling excessively; violent discharging and short circuits inside of battery.

When battery does not hold its charge, it is usually due to one or more of the above defects inside of battery—and each cell should be tested—see index "cadmium tests" and pages 410, 416, 470.

*See Inst. 29—pages 422, 416 for Battery Troubles of the Starting and Lighting System.
†See also page 470.

Overheating caused by overcharging may occur if the regulation goes wrong and permits the generator to deliver excessive current.

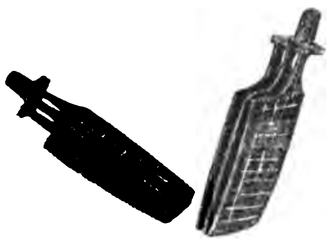

Fig. 4. A buckled plate.

It would be well occasionally to feel your battery, particularly the lead links and cover, after a long, hard drive. Should you suspect overheating, remove the vents from the cells and insert a thermometer, of the type made for insertion into liquids, into the electrolyte of each cell. The battery temperature should never be allowed to exceed 110° F. Garage men who make a practice of charging batteries in their plant should enforce this rule rigidly.

Overheating should be avoided, because it expedites evaporation of water from the electrolyte, causes deterioration of plates and separators, and tends to buckle the plates. Overheating of one half the battery should be guarded against especially in "double voltage" systems.‡

*Diagnosing Troubles Due to the Battery. See also, page 577.

If trouble should develop, as shown by the engine not cranking properly, lights burning dimly or "missing" of the engine when battery is used for ignition, look for the cause as indicated below.

(1) Make sure that all †**connections are tight** and that all contacts are clean.

(2) **Take a hydrometer reading** of each cell. If battery is found to be exhausted (gravity 1.150 or thereabout), give a special charge, outside source.

(3) If after having been fully charged, the battery is soon exhausted again, there is trouble somewhere else in the system, which should be located and corrected.

(4) The wiring may have become grounded to the frame of the car, and cause a leakage of current which in time may completely discharge the battery.

This may be tested for as follows: At night or in dark garage, turn on all the lamp switches, but remove the bulbs from the sockets and disconnect the battery ground wire at the ground plate. Then strike the bare end or terminal of the ground wire against the ground plate; if sparks are noticed, there is a ground in the wiring, which should be looked for and removed. (See fig. 6, page 413.)

(5) If a broken jar or short circuited cell is indicated (gravity considerably lower than in other cells), have the battery repaired.

When lamps burn dimly, turn on all the lamps and read the voltage with a low reading portable volt meter of each cell or of the battery—see pages 416, 410.

If the voltage per cell is 2 volts or thereabout, the trouble is in the connections.

If cell voltage is low (1.8 volts or lower), the trouble is in the battery. See pages 456, 416, 410.

When lamps burn brightly, but engine will not crank, notice when attempting to start engine whether lamps become very dim or go out; if they do, the trouble is in the battery.

If they continue to burn brightly, the trouble is in the motor or motor circuit.

Locating Battery Troubles with a Hydrometer.

A battery is said to be on open circuit when no proper circuit through which it could discharge is closed, as with a lighting or starting switch. Ability to maintain the specific gravity under such conditions, likewise means ability to hold the charge. The best way to test the battery in this respect is to insure a full charge as with a drive in the evening, to test all cells and make a note of the readings, and to again test the gravities with the hydrometer the next morning after, say 10 hours, have elapsed since charging. If all cells maintain the gravity uniformly well, under such conditions you may be sure that the battery is in excellent health.

Low gravity in all cells. If your starter occasionally fails to spin your engine, and if you confirm your suspicions that the battery lacks energy, by testing with hydrometer and finding the "gravity" low, say below 1.225 it may be that all the battery requires is an extra charge. You may have previously discharged your battery to so low a state that the normal generator output has not been sufficient to restore it. If failure due to low gravity recurs after this extra charge, you will know that your generator is failing to put enough current into the battery, and that the generating function must be tuned up. Or it may be that a short-circuit in the wiring is dissipating the battery energy.

Low gravity in one cell. Should you find the gravity low in any cell, say 50 points lower than in the others, regard that cell with suspicion. Hydromete the cells oftener to determine whether the difference in gravities of the cells is increasing. If the trouble increases, the cause undoubtedly is that a short-circuit is commencing. Some one of the following conditions must be the cause: separators wearing through, or "mud" accumulating in the bottom of the jar until it touches the plates, or a piece of metal has fallen into the cell and has bridged across the plates. Again, water containing certain minerals may have been put into the cell and these minerals have prevented the cell from holding its charge. The remedy is the same, whatever the cause. The element must be taken out and the cause removed. New separators should in almost every instance, be installed in all cells.

A broken jar is sometimes the cause of persistent low "gravity" in a cell. You can usually detect a broken jar from the fact that you will have to add water more frequently to its cell than to the others, to keep the plates covered. The electrolyte leaks through the crack in the jar and seeps out between the jar walls and sealing compound. The greater admixture of water to replace the electrolyte lost from such a cell, will naturally reduce that cell's "gravity." We

*Also see pages 421 and 422. †**A common trouble** is one where connections of wire terminals to battery and ground connection to frame of car are not properly made—see page 421.

‡**Double voltage system means** where there are two different circuits to battery; using different voltages—see page 466.

find, however, that 95 per cent of all cases of supposed leaks, are not leaks at all but are simply the result of adding too much water.

Sulphation and low gravity. If the battery has been properly attended to there has been no chance for sulphation. But, suppose you have owned a battery for some time and have just acquired virtuous battery habits, so that you can vouch for what has been going on in your battery. And suppose you observe that the gravity of a certain cell is persistently low, and that you have to add water too frequently to that cell to keep its plates covered. Mark that this by no means convicts the jar. You may have previously been inattentive, or at least partial with the water ministration. As a result the tops of that cell's plates may have been left exposed to the air for a spell, and so the plate tops may have become sulphated, and the disease has proceeded downward so as to affect the plates throughout. Then, if this evil had progressed far enough, the cell would not respond to charging and the "gravity" would not rise. The cell would become unduly hot during charge and would hasten the evaporation of water.

1.150 or lower. With "gravity" as low as this, the battery cannot be depended upon even to operate the lights.

Gravity too low to read. Hydrometer markings generally run as low as 1.150. Batteries may be found with gravities too low to be measured with the ordinary hydrometer, so that you cannot fully diagnose the battery with this instrument alone. These are extreme cases and require an expert's attention. Possibly all they require is a thorough charge, but the special conditions of the necessary charge must be observed. Should there be sulphation—and there is likely to be if the battery has stood long in a state of low "gravity"—the rate of charge secured in the automobile would undoubtedly overheat and buckle the plates and so injure both plates and separators and cause an early finish of the battery's career.

Constantly high "gravity." While we have indicated 1.285 as the proper top mark for full charge, a reading of 1.300 of itself need cause no alarm. However, if a few hydrometer tests, and a study of your driving habits show you that you are regularly charging your battery for considerable periods after the "gravity" reaches 1.285, it is up to you to do something to abbreviate your charging, for your battery is getting more than enough, and you are daily shortening its normal life. Have the generator output reduced. And to clinch the improvement have a touring switch installed (see page 427.)

Excessive gravity. Gravity above 1.300 is certainly abnormal and points the accusing finger unerringly to the man who "doped" the battery with excess acid. Prompt reduction of the acid proportion is needed to save the battery's life.

*A Digest of Battery Troubles: Cause and Remedy.

Liquid low in one cell.—Cause; cracked or broken jar.—Remedy; new jar.

Electrolyte gravity won't rise.—Cause; sulphated.—

Sulphation.—Indication: gravity cannot be brought up by charging. Cause: overdischarge; standing discharged; raw acid added to replace evaporation instead of water; electrolyte level constantly low; internal short circuits. Remedy: give long 24 hr. charge at low rate. If this fails, put in new elements; balance electrolyte in each cell and charge for long period. See also, pages 461, 456 and top of this page.

Overheating.—Cause; liquid low or charged too rapidly.—Remedy; refill with water and inspect regularly, or alter generator regulation.

Electrolyte leaking at top.—Cause; solution too high.—Remedy; draw out a quantity with syringe.

Battery constantly low.—Cause; under-charging.—Remedy; examine generator brushes, if o. k. increase charging rate and have battery charged from an outside source.

Buckled plates.—Cause; sulphation; overheating.—Remedy; charge at lower rate—keep liquid in cell—keep temperature below 110 deg. Give a 24 hr. charge.

Battery exhausts quickly while idle.—Cause; short circuits or grounds—Remedy; go over wiring.

Frozen battery.—See page 451.

Rotting insulators.—Cause; impure water—too much acid.—Remedy use distilled water only or melted artificial ice.**

Battery won't take charge.—Cause; connectors loose—see crystallized plates.—Remedy resolder connectors and plate holders.

Terminals corroded.—Cause; acid leak through vents.—Remedy clean with ammonia or washing soda.

Jars break repidly.—Cause; battery not fastened down.—Remedy; see that proper cleats and bolts are fitted.

Separators punctured.—Cause; overheating.—Remedy; renew separator and keep battery filled.

Lights rise and fall.—Cause; battery low.—Remedy; recharge outside or by long run at 20 m. p. h.

Battery won't operate after storage.—Cause; not maintained during storage.—Remedy should have been kept charged—probably cannot be repaired owing to disintegration.

Lamps dim although electrolyte at high level.—Cause; specific gravity too low.—Remedy; bring specific gravity up to 1.275 by charging—see that generator gives 20 per cent more current than lamp consumption.

Electrolyte down to 1.100.—Cause; overdischarge.—Remedy; give reforming charge at 3 amps. until up to maximum density.

One cell dead.—Cause; insulation destroyed.—Remedy; watch overheating and overcharging— keep electrolyte up.

Battery dead from usage.—Cause; using without restoring.—Remedy; charge for 24 hr. at rate marked on battery or until electrolyte reaches 1.275.

Large sediment deposit.—Cause; active material dropping.—Remedy; take battery to service station at once, as material has become loosened.

Storage Battery Pointers.

(1) **Learn to prepare the electrolyte.** Use a large earthen crock or lead vessel with burnt seams. One part of chemically pure concentrated sulphuric acid, is mixed with several parts of water, the proportion of water varying with the type of cell. (see pages 448 and 451.)

(2) **Prepared electrolyte** may be purchased if desired —see page 473.

(3) **Always pour the acid into the water, never the reverse.**

(4) **Use pure water, either distilled or rain water.**

(5) **Allow the electrolyte to cool** before placing in the cells. The specific gravity should be 1.200 or 25 degrees Baume. Add distilled water if a higher reading is obtained.

(6) **Grids should always be at least ½** inch below the surface of the solution.

(7) **Woolen clothing is little affected** by acid.

(8) **Ammonia immediately applied to a splash of acid on the clothes, neutralizes** the acid and prevents a hole being burnt in the material.

(9) **In case a bit of acid splashes into the eye,** wash well with warm water and put into the eye a drop of olive oil.

(10) **Avoid the use of an open flame in a room where a storage battery is being charged,** or in which it has been left for some time, as an explosive mixture of air and hydrogen may be formed.

(11) **Storage batteries are rated in ampere-hour,** this being based on the steady current the battery will discharge. A battery that will discharge at five amperes for eight hours without the voltage

Distilled water: Artificial ice is not **always made of distilled water. Rain water can be used if it does not come from a metal roof or where mineral substances will get into it. Drug stores have small distillers which consist of a glass tube in which water is boiled and the steam condensed into distilled water. Filtered water will not do. See page 709 for a home made still.

*Also see pages 422-423, 416, 410. See also, page 577 for a "Digest of starting motor and generator troubles".

falling below 1.75 is rated as a 40-ampere-hour battery. This does not mean that 40 amperes would be the output of the battery if discharged in one hour. The ampere-hour capacity decreases with the increase in current output.

(12) **The current in charging** should be kept within the maker's specified limit. One authority advises for rapid charging covering a period of three hours, 50 per cent, 33 per cent and 16 two-thirds per cent of the total current for each consecutive hour.

(13) **The e. m. f. of the charging current at starting the charge,** should be about five per cent higher than the normal e. m. f. of the battery. After a few minutes this voltage may be 10 or 15 per cent higher than the normal battery e. m. f. However, the battery is kept in the best condition by using a constant charging current and if necessary to maintain this, the voltage may be raised to 25 per cent higher than the normal battery voltage.

(14) **Be sure the positive pole of the charging mains is connected to the positive side of the battery.**

(15) **To determine the polarity** hold the two wires in a glass of acidulated water or electrolyte, keeping them at least ½ in. apart. Gas will collect most at the negative lead.

(16) **A cell is fully charged:** (a) If, with a constant current, the voltage and specific gravity do not change in one hour. (b) When the plates decidedly increase the quantity of gas given off. (c) When the specific gravity measures 1.275, and the voltage from 2.5 to 2.7. (d) When the negative plate assumes a light gray color and the positive plate turns a dark brown.

(17) **Never adopt the method of putting a wire across the positive and negative terminals, to see if there is any "spark."** It is almost a dead short-circuit, and if the cell be of a small capacity of, say 30 ampere-hour, and the wire No. 16 copper the current may be anything from 80 to 100 amperes for a fraction of time, which, when calculated, is a very appreciable amount of the total capacity, if only for a second of time duration. It is also very detrimental to the cell, assisting the disintegration of the plates or active material thereon.

(18) **Lead cells** should not be discharged below 1.7 volts.

(19) **Excessive boiling** will loosen the active material.

(20) **If the cells are hot while charging,** reduce the charging current.

(21) **If a battery is not in use, give it a short charge** once a month.

(22) **If white sulphate is formed on the grids,** it may be reduced by charging at a high rate for a few hours and overcharging at a low rate for two or three days.

(23) **Continued sulphating will buckle the plates,** as will also too rapid discharging.

(24) **A cell that has been short-circuited, should be disconnected from the battery and charged and** discharged several times separately.

(25) **Makers furnish directions for keeping batteries when not in use.** One way to do this is to charge the battery fully, then siphon the electrolyte out of the jars, to be kept until used again. The plates must then be removed and stored.

(26) **Never allow the cells to stand in a discharged condition,** as it becomes very difficult to get them properly charged if left standing any length of time, unless great care is taken during the succeeding charge.

(27) **If the terminals begin to corrode,** use vaseline.

(28) **Voltage readings** should be taken only when charging or discharging.

(29) **Do not let the battery get too warm;** its temperature should never exceed 100° F.

(30) **Use only distilled water to replace losses from** evaporation. Add acid only in special cases.

(31) **Each time you charge,** bring the gravity up to maximum, or charge until it has remained constant, for at least one hour in every cell.

(32) **When charging the battery, put in at least 20 per cent more current** (ampere hours) than is taken out, and at every third charge give it a 50 per cent over-charge, at the finish rate for the general good of the battery.

(33) **Voltage readings are only approximate.** Gravity readings give correct indications.

(34) **Keep the box containing the battery perfectly dry.** If any acid is spilled into the box, wipe it off carefully with a piece of waste dipped in ammonia water.

(35) **When charging at the finish rate or 24-hour rate,** leave battery on until bubbles begin to rise in the electrolyte, then for at least one hour longer.

(36) **Never add acid or electrolyte to the cells except to replace loss from spilling.**

(37) **In cases where the specific gravity will not show any rise** during or at the end of its charge, it indicates a short circuit, and the cell has not received its charge.

(38) **In cases where the specific gravity comes up to 1.250 at the end of its charge, but falls** to a lower figure during a period of idleness or standing for say twenty-four to forty-eight hours, this also indicates a short circuit, or else local action (or internal discharge), due to contamination of the electrolyte by some impurity.

**Charging a Battery.

The charge must always be given from a "direct" current circuit (never an alternating, unless a rectifier is used), and great care taken to **connect the positive wire to the positive terminal of the battery** either directly or through the *resistance which is usually necessary; the negative wire must then, of course, be connected to the negative terminal of the battery. **If connected in the reverse direction,** very serious injury to the battery will result. To test for polarity, see page 452.

Reversed charge: Should a reversal occur, put the battery on charge at the 24-hour rate and leave it on for several days. Do not take it off until its voltage and gravity both have reached a maximum, with battery at normal temperature, 70 degrees F.

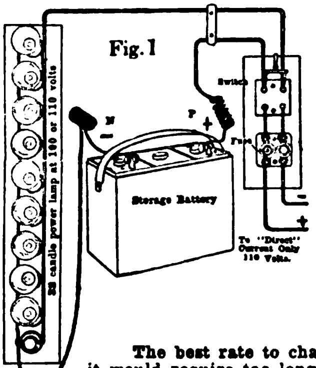
Charging rate. Start the charge at a rate equal to the normal charging rate (start) or lower, as shown in the tables and continue the charge until the cells gas freely. This will ordinarily take about six hours. Then continue the charge for six hours at the normal rate (finish), see tables, page 467.

A battery charge is complete when, with charging current flowing at the finish rate given in the tables, all cells are gassing (bubbling) freely and evenly and the gravity of all cells have shown no further rise during one hour.

The 24-hour rate is the one used for charging through the night, and cells charging at this rate may be left on continuously.

If you have no voltmeter nor hydrometer, it is possible to determine when the battery is fully charged by observing when gas bubbles begin to rise from the solution while battery is charging at the 24-hour rate.

*See page 474. ** See also, page 470 for charging a repaired battery. To find polarity of a battery when charging, see pages 737, 452.



Charging Storage Batteries from a *110 Volt Direct Current Circuit Using Lamps.

A storage battery can be charged from a 110, 220 or 500 volt direct current circuit by merely placing lamps into circuit, so that the current in passing through the lamps must pass through the battery. The lamp method is not an efficient method. Some of the small garages utilize the lamps for lighting the garage—see page 465.

The amount of current or amperes, depends upon the candle power or watt capacity of the lamp and the method of connection.

A 32 c. p. 110 volt, carbon filament lamp will pass approximately 1 ampere and is a 100 watt lamp. Watts are found by multiplying the voltage of the circuit (100 volts used instead of 110, which is near enough in this instance) by the ampere capacity, as 100 volts × 1 amp. = 100 watts.

A 16 c. p. 110 volt carbon filament lamp will pass ½ ampere and is a 50 watt lamp.

To Charge a Single Battery.

The best rate to charge any battery is at a slow rate for a long time, but in many instances it would require too long a time. About a 6 ampere rate would be best for small batteries, but if battery is a 90 or 100 ampere-hour "starting and lighting" battery, we will use say, 10 amperes, or 10, 32 c. p. 110 volt lamps, per fig. 1 (only 9 lamps shown). Lamps are connected in "parallel," or across the line and battery is connected in "series" with the bank of lamps.

A high rate will charge the battery quicker but battery heats up quicker, which is injurious to battery. In fact, in charging any battery the temperature should not be above 110 degrees and if it rises to this point the charge is too heavy and should be cut down. **To find the polarity of charging wires and battery,** see page 452.

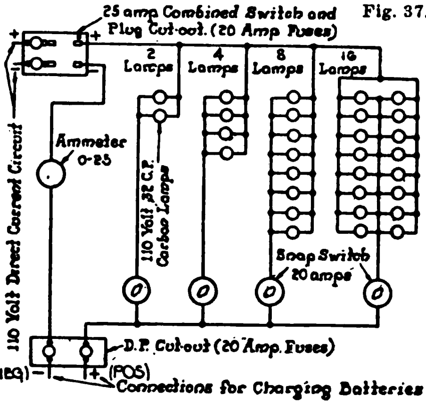


Fig. 37.

Charging 1 to 11 Batteries.

Place batteries in "series" per fig. 4, page 462. Then use the number of lamps per table below. We are assuming that charging circuit is a 110 volt direct.

Number of Batteries	No. of 32 c. p. 110 v. Lamps at "start" and amp's.	No. Lamps for "finish" rate	No Lamps for "24 hour" rate
1	10L—10a	3L	5L
2	10L— 9½a	3L	5L
3	11L— 9[illegible]a	3L	5L
4	12L— 9[illegible]a	4L	6L
5	13L— 9[illegible]a	4L	6L
6	15L—10[illegible]a	4L	7L
7	17L—10[illegible]a	5L	8L
8	19L—10[illegible]a	6L	9L
9	21L— 9[illegible]a	6L	10L
10	25L—10a	8L	12L
11	30L— 9[illegible]a	9L	15L

L designates **lamps** in circuit and **a, amperes** passing to battery.

It will be observed, that to charge more than one battery, more lamps are used in order to obtain the same amperage rate of charge, or nearly the same. This is due to the fact that as each battery is connected in series with another, the battery voltage is increased.

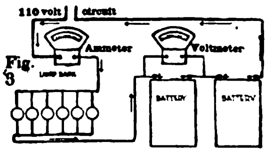

Fig. 3

When charging several batteries, the practice is to charge at 6 amperes during the day and 3 amperes at night. This permits watching in day and avoids overheating at night.

Above table is figured for a discharged 90 to 100 ampere-hour 6 volt starting and lighting battery (see page 467). **If smaller batteries are on the line, or if some are partially discharged,** then charge at 24 hour rate until smaller ones or partially discharged ones are charged, then remove them.

30 Ampere, Lamp Charging Outfit.

Fig. 37 outfit has a base of hard wood and No. 12 wire is used. Various charging rates can be had by switching on banks of lamps instead of unscrewing lamps. Note 2, 4, 8 or 16 lamps can be used singly, or all together which would make 30 **amperes** total. Each 32 c. p. 110 volt lamp gives 1 ampere.

To obtain 20 amperes, switch on the 4 and 16 bank; **10 amperes,** switch on the 8 and 2 bank; **5 amperes,** put 2, 16 c. p. ½ ampere lamps in 2 bank, which would give 1 amp., and use this with the 4 bank.

Ammeter indicates quantity of current in amperes, passing to battery. It can be connected in series per figs. 37 and 3. An ordinary dash type can be used if rate of charge is not over capacity of meter. If in connecting meter, hand points wrong direction; reverse the connections to meter.

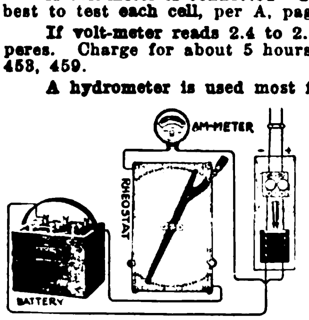
Testing Battery For Charge.

The battery requires careful watching. A volt-meter or hydrometer or both can be used for testing.

A volt-meter is connected "across the line" per fig. 3. which is shown testing the entire battery. It is best to test **each cell,** per A, page 416. See also, page 864D to 864E.

If volt-meter reads 2.4 to 2.5 volts per cell when charging, decrease number of lamps to 2½ to 3 amperes. Charge for about 5 hours more and if still reads 2.5 volts, charging is complete—see also pages 458, 459.

A hydrometer is used most for testing during charge. If on a test the specific gravity (s. g.) shows 1275 to 1300 and battery "gases" freely, then reduce charge to 2½ or 3 amperes for say 5 hours more, being sure temperature does not rise over 110 degrees. If s. g. does not change, battery is charged. See also page 459. The 2½ amperes can be obtained by using 2—32 c. p. lamps and 1—16 c. p. 110 volt lamp.



On some old batteries the s. g. may not rise above 1250, then it is a matter of using it and recharging again soon.

A Rheostat

Shown in fig. 25 is a wire resistance, mounted on the back of a slate base. The resistance is iron wire, German silver or other kind of resistance wire which can be placed in the circuit, more or less amount, by movement of lever. See also page 464 and pages 474, 864K.

CHART NO. 205—Charging Storage Batteries with Direct Current from a Lighting Circuit, using Electric Lamps. A Rheostat. *See page 465 for charging from 220 and 500 volt circuit.

Hurrying a charge; this is not recommended, but when unavoidable proceed as follows:

Put the battery on **double the "start"** rate given for your battery in the table of rates, chart 205-D.

Lighting batteries can be placed on the line with batteries capable of taking a charging rate higher than that usually given to sparking batteries, and at all times the batteries should be left on until gravity has reached its maximum and remained stationary at this maximum for at least an hour.

Charging Rates.

Commence the charge at the current rate given under "start" Chart 205-D. Be sure that the rate is correct for the particular type of battery. Continue to charge at the maximum rate until the cells begin to gas or bubble freely, at which time the voltage will be approximately 2.5 volts per cell (7.5 volts for a 6-volt battery). When one or both of these conditions are obtained, reduce the charging current to the value given under "**finish,**" chart 205-D by unscrewing the proper number of lamps (if charging as per chart 205), and continue to charge at this rate until the cells again gas freely, and the specific gravity of the electrolyte ceases to rise, as indicated by successive half-hour readings taken after the cells begin to gas.

At the end of charge the voltage will be approximately 2.5 volts per cell with the current flowing at the minimum rate, but on a new battery this voltage will be greater, reaching as high as 2.65 volts per cell.

‡**The specific gravity of the electrolyte at the end of charge** should be at a maximum between the value 1.275 and 1.285. Correct all specific gravity readings for temperature as described under "specific gravity," page 449. Make sure that the battery is full, but do not overcharge.

The temperature of the electrolyte should not be allowed to exceed 100° Fahrenheit during charge. If this temperature is exceeded, cool the battery by reducing the charging current, or by temporarily stopping the charge.

Charging and Discharging Sulphated Batteries.

With the sulphated battery, the charging should begin at about a two or three-ampere rate and should not be allowed to raise beyond five or six amperes. A thermometer reading should be made every hour and the temperature of the solution should never be much over 100 degrees Fahrenheit. Never let it heat more than 110 degrees. When the cells begin to gas and give off bubbles, take the battery off of the charger and discharge the battery by connecting some lamps on it or some resistance across its terminals. Put in just enough lamps or resistance to draw a discharge current equal to 1/10 the ampere hour capacity; (if 80 ampere hour batteries, discharge at an 8-ampere rate) discharge the battery until each cell has a voltage of 1.6 to 1.7 volts while the battery is discharging. Repeat this process from two to three times and the sulphate will be well broken down and the battery in good condition. See also page 470.

Charging Circuit.

†**Resistance required:** If only one battery is to be charged from a **110 volt direct current circuit,** resistance must be used in series with the battery to reduce the voltage of the circuit to that of the battery.

The most convenient resistances to use are 110 volt 32 candle power **carbon filament lamps,** connected in parallel with each other, and the combination in series with the battery (chart 205). With this arrangement each lamp will allow one ampere of charging current to pass through the battery, so that the number of lamps required will depend upon the charge rate of the battery (tables, chart 205-D).

For instance, for type XC-15, "Exide," charge rate 7 amperes, seven lamps will be required.

If 32 candle power lamps are not available, then double the number of 16 candle power lamps will be required as the current rating is only ½ of that of the 32 c. p. lamps.

If tungsten or other high efficiency lamps are used, more than twice as many will be required than if carbon filament lamps are used, owing to the lower current rating of the former.

If the battery is to be charged from a **220 volt circuit,** use two lamps in series in place of each of the lamps necessary when charging from 110 volts, and twice as many lamps, if they are not 220 volt lamps, see page 465.

If only a **500 volt circuit** is available, it is necessary to use five lamps in series in place of each of the lamps used when charging from 110 volts. (See fig. 15, chart 205-B).

*Charging Equipment for a Shop.

Install the necessary wiring, etc., so that batteries can be easily connected up and charged where they stand on the bench. Apply vaseline freely to battery terminals and exposed copper wire.

Lamp resistance: Thirty ordinary lamp sockets are mounted on a board and wired up to snap switches in groups containing two, four eight and sixteen lamps respectively. A suitable main switch, fuse cutout, ammeter and terminal block complete the outfit.

Any good electrician will understand this layout and can make it up and install it quickly and at moderate expense.

With this equipment from one to twelve 3 cell batteries can be connected in series (the positive terminal of one connected to the negative terminal of the next and so on) and charged at one time.

The lamps which are in series with the batteries make it possible to regulate the current passing through the battery to the proper value. Different combinations of the switches permit

*Fig. 37, page 460. †See page 474 for explanation of a "rheostat."—A complete charging plant including gasoline engine and dynamo—see page 824, also page 864L. ‡See also, page 864E and page 471, how to adjust or balance electrolyte.

*Belt Driven Generator for Charging Storage Batteries.

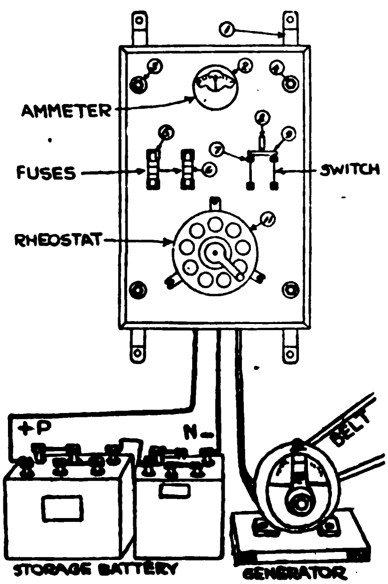


Fig. 1 Belt driven generator and switchboard.

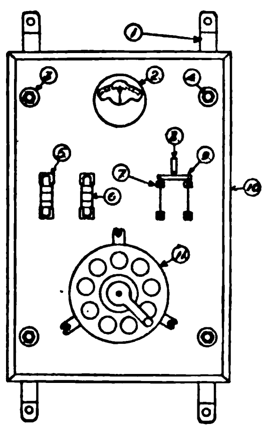

Fig. 2. Switch board.

Fig. 1.—Battery charging outfit which can be operated from line shaft, engine, or any other source. Speed of dynamo is 2,000 r.p.m. ⅓ h. p. required to operate. Will charge any battery or combination of batteries not exceeding 30 volts. Any voltage: 6, 12, 18, 24 or 30 volts.

Fig. 2 — Switch-board of a typical battery charging outfit.

(1) Brackets for support; (2) double reading ampere meter; (3 & 4) bolts, (5 & 6) fuses; (7-8-9) double pole single throw switch; (10) slate slab (11) rheostat resistance.

This outfit sells for a reasonable price and would soon pay for itself in any garage.

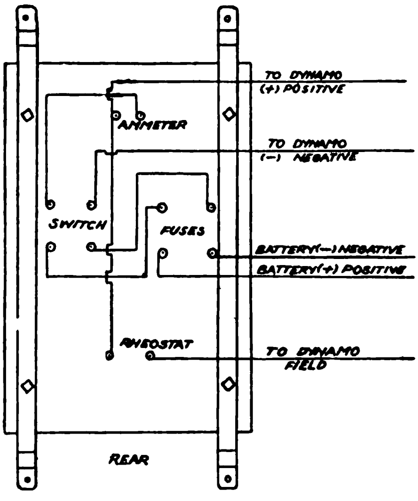

Fig. 3—Rear of switch-board showing connections.

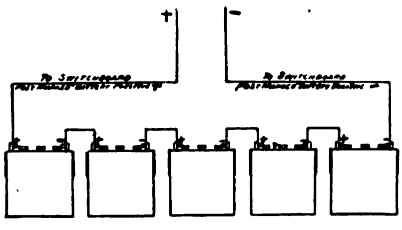

Fig. 4—Method of connecting batteries to be charged, (in series).

Any combination of voltages can be had up to 30 volts.

For instance 5, 6 volt batteries could be connected in series, or one 18 volt and one 12 volt battery—or two 12 volt and one 6 volt, etc. See also, page 864K.

**The G. E. Motor-Generator (fig. 5 below).

Fig. 5. This battery-charging outfit is designed especially for the purpose of recharging automobile lighting and ignition batteries. The outfits are furnished in five sizes, suitable for the private garage to that required for the large public garage which has quite a number of batteries to recharge daily.

The outfits consist of a small motor-generator set (either alternating or direct current motor coupled to direct current generator) with switchboard panel mounted thereon.

The switchboard panel has a voltmeter for indicating the voltage, and an ammeter for indicating the amperes of the charging current delivered to the batteries being charged.

There is also a generator field rheostat for controlling the charging voltage and current, and a snap switch arranged to open or close both charging and motor circuits at a single turn.

Ratings of outfits: These outfits are furnished for service on either 110 or 220 volts, 60 cycles alternating current circuits, or for 110 or 220 volts direct current circuits, and as before stated, are furnished in five sizes, 175, 250, 375, 500 and 750 watts output. The 175- and 250-watt outfits, can be furnished for generator voltages of 12, 18 or 24 volts as desired. The 375-watt outfit is furnished for 36 volts, the 500-watt outfit for 48 volts, and the 750-watt outfit for 72 volts.

The rheostat mounted on the switchboards have in all cases sufficient capacity to reduce the voltage generated to one-quarter of that for which the outfit is rated.

By reducing the voltage generated by means of the rheostat, the 24-volt outfits can therefore be used for charging batteries as follows:

One 6-volt battery.
One 12-volt battery.
Two 6-volt batteries
Two 12-volt batteries.
Three-6-volt batteries.
One 18-volt battery.
Four 6-volt batteries.
One 24-volt battery.
One 6 and 1-12v. bat.
One 6 and 1-18v. bat.
Two 6 and 1-12v. bat.

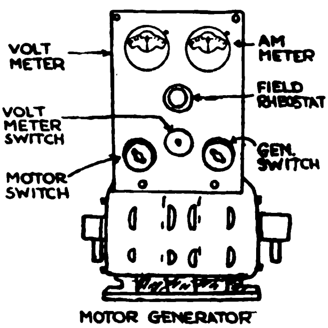

Fig. 5. General Electric Motor-Generator Set.

CHART NO. 205-A—Battery Charging Outfits; Belt Driven Generator; Motor-Generator Set.

*See pages 864K to 864L. Note the type 9G direct current generator and 9R switchboard. **See 9G motor generator set of another make, pages 864K, 864L.

current to pass through two, four, six and eight and so on up to all thirty lamps and then through the batteries in series with them.

‡**Resistance unit:** Instead of lamps, resistance units (fig. 11, chart 205-AA) of approximately 35 ohms *resistance and 3.3. amperes capacity each may be used. This equipment will occupy less space than the lamps and serve the same purpose.

††**Rheostat:—Instead of either a lamp resistance or unit resistance panel, a rheostat can be used, see fig. 25, page 460.**

Number of Batteries to Charge (each having 3 cells)	To Charge Batteries at 3 Amps. Ohms of Resistance Necessary	Tap To Which To Connect Battery	To Charge Batteries at 5 Amps. Ohms of Resistance Necessary	Tap To Which Connect Battery
1	34.0	A	20.7	F
2	32.5	B	19.5	G
3	30.3	C	18.3	H
4	28.2	D	16.9	I
5	26.2	K	15.7	J

Fig. 18. Table showing ohms resistance required for battery charging—referred to in chart 205-AA.

Rectifiers.

Alternating current flows alternately in opposite directions and is used to a great extent for house lighting. Only **direct current** which is constant or a continuous current, is suitable for charging storage batteries.

Alternating current can be rectified so it will flow in one and the same direction. It can then be used for charging storage batteries and such a device is called a **rectifier.**

There are several types of rectifiers as follows:

1—Chemical rectifier, page 466.
2—Mercury arc rectifier, page 465.
3—Motor-generator set, page 462, 864K.
4—Synchronous commutator type.
5—Tungar rectifier, page 465.
6—Vibrator type, 465, 466, 864L.

The synchronous commutator type rectifier is merely an alternating current motor with which a commutator is used to change the alternating current to direct current.

The vibrator type rectifier is divided into two classes; one whereby the storage battery being charged, determines the polarity of the charge and the other whereby a permanent-magnet determines the polarity of the charge, per page 465, fig. 62.

With this, and previous mentioned rectifiers it is important that positive and negative poles of battery be connected to the positive and negative of the rectifier.

On one other type of vibrator rectifier, which is similar to fig. 62, page 465, but minus the permanent-magnet, there is another winding on the electro-magnet, which is "shunted" across the battery terminals and which takes the place of the permanent magnet.

****With this type it does not matter which of the terminals connects with the battery, as the voltage** from the battery will set up its polarity in the electro-magnet. The disadvantage, however, is that if battery is almost totally discharged there will not be sufficient voltage to excite the electro-magnet which should determine the polarity of the charge.

Water Rheostat and Chemical Rectifier.

More or less confusion exists, relative to the difference between a Rectifier and a Water Rheostat, due to their similarity of construction.

They are however, vastly different both as to action and principle.

One of the most undesirable features of Rectifiers similar to that shown in fig. 22, chart 205-C, is its internal resistance, whilst in a water rheostat, the resistance is its main feature.

Where current is rectified from alternating to direct by chemical action, the current flows in one direction, and deposits a coating of aluminum hydroxide, which insulates the aluminum electrode, from the liquid. This must be scraped off from time to time, to keep down as much resistance as possible.

The construction and action of a water rheostat is as follows: Say current is to be taken from 500 volt direct current—to pass 8 to 9 amperes; use a 5 gallon stone jar and mix 1 part sulphuric acid to 8 gallons water. Use 2 lead plates or soft metal as electrodes; the main requisite being that they have sufficient area to keep the heating effect down as low as possible. Current applied at one terminal leaves the plate and passes through the water to the other plate. One of these is made stationary and the other movable and the resistance is regulated by changing their relative distance apart. The farther they are apart the greater the resistance. During the action of the rheostat, the water is decomposed into its natural elements,—oxygen and hydrogen,—and the loss must be made up occasionally by the addition of more water.

The prime object of a rheostat (see page 474) is to cut down the voltage; of a **rectifier,** to change alternating current into direct current.

***Storage Battery Repairing.

To properly repair storage batteries the tools and supplies as well as a lead burning outfit is required, as per chart 205-F.

†**The usual battery troubles are sulphating and buckling of plates, broken down separators and sediment accumulation in the bottom of the jar.**

To repair a battery it must first be disassembled.. Before disassembling the defective cell should be located by testing, and inasmuch as other cells may be on the verge of a break-down it is advisable to disassemble all cells. If other cells are not defective, they should be washed and new separators added

Disassembling.

To disassemble: The first step is to remove the filling plugs, to give more room to work upon the battery terminals. Then disconnect the terminals and intercell connectors, the sealing compound which covers the jar is removed first by using a hot putty knife. Steam or a flame is also used to first soften the compound.

Next: Remove connectors (fig. 23, chart 205-E) as follows: take a brace with a ⅝ inch wood bit and bore lead connector centrally over each post. (Fig. 24.) Then work off with a pair of pliers—another method; is to play a burning flame on the joint, at the same time pulling connector with a pair of pliers.

Be careful gas is not coming out of cell when handling a flame about it.

—continued on page 469.

*See page 207 "ohms" and 209 "resistance."

****When charging with the rectifier, the matter of connecting the positive of the charging source to positive of the battery is important** on all rectifiers except this one. ‡Can be obtained of Domestic Engineering Co., Dayton, Ohio.

***These directions do not apply to any particular make of battery. We have used the "Exide" in many instances, to show relation of one part to another.

†**When to tear down a battery;** when one or all of the cells do not take a charge after being on charge for 24 hours—then make a "cadmium test," page 864D. ††See page 474.

Parts necessary to construct this 5 battery, charging outfit:

1—Double pole single throw switch.
2—10 amp. plug cut outs (fuses).
1—Ammeter, reading 0 to 30 amperes.
40 ft. of No. 16 rubber covered flexible wire.
1—Resistance unit with two taps.
1—Resistance unit with nine taps.

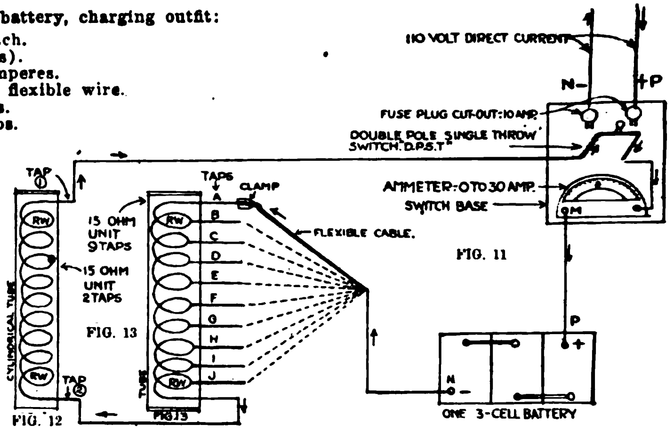

Fig. 11.—Resistance charging circuit.

Construction — The resistance units can be had of the General Electric Co. of Schenectady, N. Y. They are merely coils of wire (spiral resistance wire) wound on cylindrical tubes over asbestos and baked on the cylinder. The tubes are encased in porcelain and measure 22 inches long and 2 inches di.

Taps—There are two taps from each single resistance unit (fig. 12). Fig. 13 has 11 taps or connections. Each resistance unit in this example has 15 ohms capacity and is known as the 15E form P.

These resistance units are inexpensive, costing in the neighborhood of one dollar each.

teries. If a battery has 6 cells it is treated the same as two, 3-cell batteries; if it has 9 cells, it is treated the same as three, 3-cell batteries, etc. To figure the amount of resistance necessary to charge 1 o 5 batteries, that is; 3-cell batteries, on a 110 volt direct current line, note the following:

Resistance is always referred to as so many "ohms"—if one 3-cell battery is to be charged at a 3 amperage rate, figure resistance necessary to put in series with the battery as follows: N × SV = TV. In which N stands for number of cells, SV, stands for single voltage, or the voltage of one cell, and TV stands for total voltage. Submitting the letters for figures we have—3 cells (N) × 2.1 volts (SV) = 6.3 volts (TV). The total voltage of a 3-cell, 6-volt battery at beginning of charge.

$$\frac{110V - 6.3V}{3\text{ amp.}} = 34.6 \text{ ohms} = \text{resistance required.}$$

Arrived at as follows; 110 — 6.3 = 103.7 ÷ 3 = 34.6.

If two, 3-cell batteries are to be charged at 3 ampere charge; multiply the 6.3V in above example by two—for instance:

$$\frac{110V - 12.6V}{3\text{ amp.}} = 32.5 \text{ ohms} = \text{resistance required.}$$

If three, 3-cell batteries are to be charged at 3 ampere charge; multiply the 6.3V in the first example by 3; if four 3-cell batteries are to be charged multiply by 4; etc.

If the batteries are to be charged at 5 amperes, divide by 5, instead of 3 in the above examples, for instance:

$$\frac{110V - 6.3V}{5\text{ amp.}} = 20.7 \text{ ohms} = \text{resistance required.}$$

To charge two 3-cell batteries at 5 amperes:

$$\frac{110V - 12.6V}{5\text{ amp.}} = 19.5 \text{ ohms resistance required etc.}$$

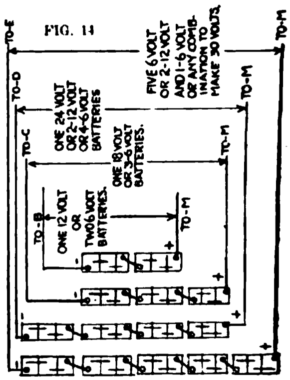

Fig. 14.—Method of connecting more than one battery to charge. Note batteries are connected in series—the positive pole of one battery, to negative pole of another, etc.

To increase the amperage of charge, say to 10 amperes per hour; divide by 10 instead of 3 or 5 amperes and cut out enough units, to give the required resistance necessary.

To operate on a higher voltage than 110 volts, as explained in the example above; say 220 or 500 volts—to find resistance necessary, use 220 or 500 instead of 110 volts.

How to charge—the two resistance units (figs. 12 and 13) in diagram, give 15 ohms each, or a total of 35 ohms (actual addition shows 30 ohms, but will give 35). One of the units (fig. 13), has 11 taps, so that the entire 11 resistance coils (RW) can be thrown into the circuit or only part of them as shown in diagram. The resistance unit (fig. 12) is connected at all times, which is 15 ohms. The other 15 ohms in fig. 13, can be subdivided as follows:

By merely connecting the wire from battery (— negative) to A—all resistance (30 ohms—will give 35) is in the circuit. When connected with (J) only the resistance in unit (fig. 12) is in circuit. Table fig. 18, page 463 will explain how and why the resistance units are added or cut out.

By following the arrow points, on diagram, from + P wire, over switch from the main wire, the circuit can easily be traced. The dotted lines represent the connections at different taps on the fig. 13 unit.

When connection is at A, this gives the least current, as the entire 30 ohms is in circuit. When at F, 22½ ohms resistance is in the circuit. The ampere current flowing may be read on the ammeter. The actual current will depend upon the number of batteries in series, as per diagram fig. 14. If the current obtained at A, is not sufficient, then cutting out resistance by connecting with B, or C and so on, each giving a greater current than the one preceding; the maximum being given at J.

As the batteries become charged the rate will become less, but may be increased again to 5 amperes, by proceeding with the next operation of cutting-out resistance. Charge until the specific gravity has reached a maximum (see page 461), and remained there for five hours. This is the standard, indicating completion of charge. The cells should gas at the same time. If they do not the maximum gravity has not been reached. The important point to watch in charging is not to let the temperature of the cell get above 110°. If it does the charge must be temporarily stopped, until the cell cools down, and then continued at a lower rate. But be sure to charge until the specific gravity has remained at a maximum for 5 hours. In case one battery becomes charged first it should be taken out of circuit and the remaining batteries charged at 5 or 6 amps. until the charge is completed.

CHART NO. 205AA—Charging Batteries with Resistance Units. A Practical Home-Made Charging Outfit—from Direct Current Source only. See page 463 for Table Showing the Ohms Resistance Required. See also 474 for explanation of resistance. A charging plant suitable for small towns where there are no electric plants and for garages is shown on pages 824 and 864L.

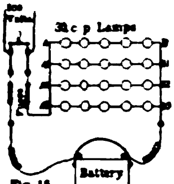

Fig 15

Charging From 500 Volt Circuit.

Fig. 15—To charge a battery from a 500 volt direct current circuit. We will use 32 c. p. 100 volt lamps. In order to not burn out the lamps, place five in series, as A to B.

The five lamps however, owing to the series connections will not allow but one ampere to pass. In order to pass **two amperes,** another bank of five are placed in a parallel or multiple connection as at A1 to B1. For **three amperes,** another row from A2 to B2. For **four amperes,** another row A3 to B3. Therefore, four amperes of current would pass to battery. If **five amperes** were desired use **five** more lamps connected as above.

Charging From a 220 Volt Circuit.

As the voltage increases the amperage decreases. Therefore a 32 c. p. 220 volt lamp takes but ½ ampere. The same method as fig. 1 and fig. 37 page 460, can be used, but use 220 volt lamps. If 10—220 volt lamps are used, arranged as shown in fig. 1 and on a 220 volt circuit, only 5 amperes would be obtained. Therefore 20, 220 volt 32 c. p. lamps would be required for 10 amperes, or 60 for 30 amperes.

Another plan would be to use 2—16 c. p. 110 volt lamps in "series," but "parallel" to the circuit per fig. 30 below. This would give 1 ampere for each pair of lamps. Therefore 8, 110 volt, 32 c. p. lamps connected per fig. 30 would give 4 amperes.

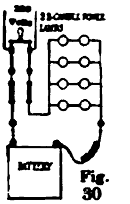

Fig. 30

Lighting Garage With The Charging Current.

A current economy in charging storage batteries can be effected by utilizing the current that is ordinarily consumed by the resistance shown in fig. 15, and on page 460, in lighting the garage at the same time. The banks of lamps can be placed separate from where the charging is being done if correct size wire is used.

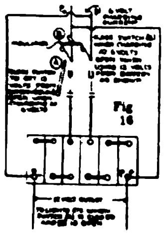

Fig 16

Charging 12 Volt Battery on 6 Volt Circuit.

Fig. 16—A simplified illustration showing how to charge a 12-volt battery from a 6-volt direct current circuit is shown in illustration. The 3rd and 4th cells are not connected, but wires connect with a single pole switch, which is closed when battery is being used for 12-volts. When being charged at 6 volts, the single pole switch (A) is opened and switch (B) places the two sets of 3 cells in parallel.

Rectifiers—see also pages 463 and 864L.

Fig. 5—The mercury arc rectifier is used considerably for charging electric vehicle batteries. A maximum of 30 amperes is the average. A large glass tube contains mercury in its base. Graphite terminals 1 and 2, are the "anodes." Terminal 3, is the "cathode" for negative wire, there being only one. G, is the transformer. A small electrode 4, connected to one side of the alternating current, is used for starting the arc across the mercury. Tilting the tube, causes a mercury bridge between the terminals and produces an arc when tube is turned in a vertical position. When the current alternates, first one, and then the other "anode" (1 and 2), becomes positive, and a continuous flow is towards the mercury "cathode" (3), thence to battery, back to opposite side of supply.

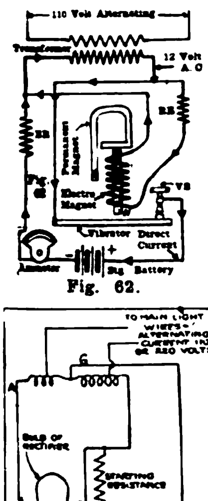

Fig. 62.

*__Figs. 59, 60—The Tungar rectifier__ consists of a hot argon low pressure gas filled bulb B, fig. 60 and fig. 59, with a "cathode" F, (Tungsten filament) and an "anode" A, transformer T, for exciting the filament, rheostat R, and the load which is shown as a storage battery. The connections in fig. 60 show the half wave rectifier in its simplest form.

Principle: Assuming an instant when the side C of the alternating-current supply is positive, the current follows the direction of the arrows through the load, rheostat, bulb, and back to the opposite side of the alternating-current line. A certain amount of the alternating current of course, goes hrough the transformer T to excite the filament, the amount depending on the capacity of the bulb.

When the alternating-eurrent supply reverses and the side D becomes positive, the current is prevented from flowing. In other words, the current is permitted to flow from the "anode" (A) to the "cathode" (F), or against the flow of emitted electrons from the cathode, but it cannot flow from the cathode to the anode with the flow of electrons.

Fig. 62—The vibrator type rectifier is divided into two classes; one with a transformer which transforms the alternating current from 110 volts to 10 or 12 volts. The current then passes through an "electro-magnet," the amount of current to operate the vibrator being regulated by resistance RE, fig. 62, page 465.

The purpose of the electro-magnet, vibrator and permanent-magnet is as follows: If the alternating current flowing through the electro-magnet is 120 cycle waves per second, the core (N) of electro-magnet would change its polarity each cycle wave.

If, however, some means were employed to **cut out 60 of the cycle waves,** and utilize only **one-half of the waves,** or only every other cycle wave which **flows in one direction** and which would be a direct flow of current, then the vibrator would close the circuit to battery at VS, and charge battery.

Fig. 5—Mercury arc rectifier for 60, 50, 40, 30 or 25 cycles, 110 volt.

This is possible, by placing a "permanent magnet" at the end of the electro-magnet, as shown in fig. 62, which keeps the electro-magnet core definitely N. & S. During the time the 60 cycle waves per second are flowing one way or in harmony with the permanent magnet polarity, the vibrator "cuts in" the battery, and during the time the 60 cycle waves flow in the other direction, the vibrator is not attracted by the core (N), because current is flowing in an opposite direction to that of the polarized magnet core and magnetism is not set up.

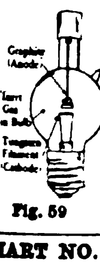

Fig. 59

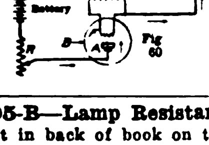

Fig 60

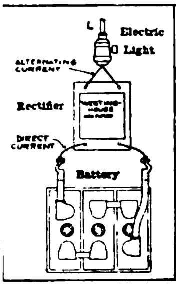
A spring, not shown, is attached to the vibrator which is adjusted to hold vibrator away from the core (N) until current flowing in harmony with the permanent magnet polarity, both combined, draws the vibrator to core. The **resistance** (BR) fig. 62, is used to limit the amount of charging current to battery, say 6 amperes.

†Positive and negative wires must be connected correctly, but on another type of **vibrator rectifier,** as explained on page 463, this is not necessary.

CHART NO. 205-B—Lamp Resistance—Continued from page 460. **Rectifiers.**

*See advertisement in back of book on the G. E. Tungar rectifier. †See page 737 to tell polarity of battery when charging from a rectifier.



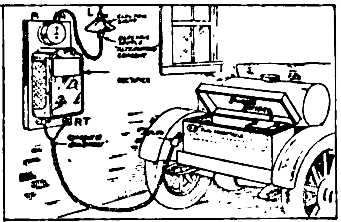


Fig. 20. A Westinghouse alternating current rectifier. Suitable for charging a storage battery.

Fig. 21—Another make of rectifier of a similar principle, is explained on page 463, 465. The current starts in one end alternating and passes out of rectifier into battery as direct current. The two above rectifiers will charge a single 3 cell battery at 5 amperes—from 110 volt circuit.

***When charging with this rectifier, the matter of connecting the positive of the charging source to the positive of the battery is not so important as it is when charging from 110 volt direct current through lamp bulb resistance, as the rectifier as soon as connected, establishes its own polarity or proper direction of current if of the "electro-magnet-vibrator type" explained on page 463.**

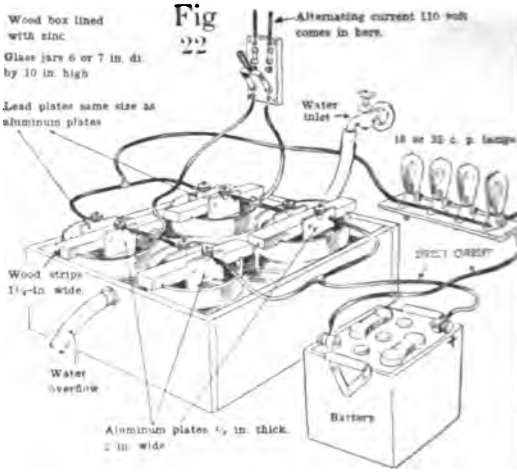

****Fig. 22—A chemical rectifier—not very efficient, but can be utilized if a better system is not available. There is a tendency for liquid in jars to get hot and boil if too high a current is passed through it, otherwise water not necessary.**

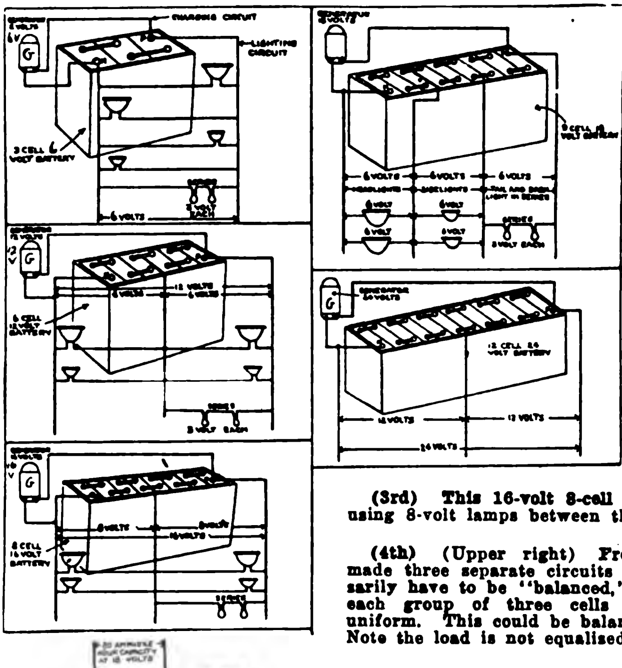


Amount of charging current is regulated by using 16 or 32 c. p. lamps, ½ ampere will pass through a 16 c. p. lamp and 1 amp. through a 32 c. p., therefore more lamps, more amperes flowing. About 2 amperes or 4—16 c. p. lamps is best with this outfit, which of course would require a long time to charge 100 ampere hour battery if entirely exhausted. (Motor Age.)

Battery Connections.

The explanation of lamp connection diagrams here shown starts with the upper left hand illustration.

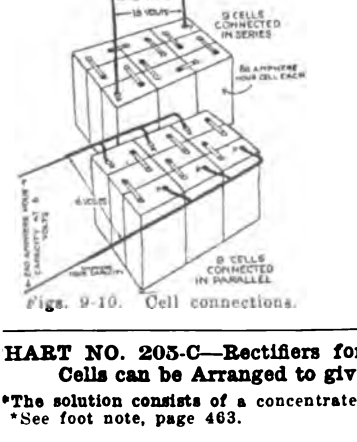
(1st) A 6-volt 3-cell battery from which the head lights are 6 volts. 3 volt tail and dash light are connected in series.

(2nd) (Just below) a 12-volt, 6-cell battery from which we have connected 6-volt lamps, using a "neutral" or third wire connection as shown in illustration. The battery is charged from a 12-volt generator.

(3rd) This 16-volt 8-cell battery is connected in the same manner, using 8-volt lamps between the third wire.

(4th) (Upper right) From the 18-volt, 9-cell battery we have made three separate circuits of 6 volt each. This system must necessarily have to be "balanced," that is, equalize the current taken from each group of three cells each, else the charging would not be uniform. This could be balanced better than shown in the illustration. Note the load is not equalised.

(5th) 24-volt, 12-cell battery divided, two circuits 12-v. each.



Figs. 9-10. Cell connections.

Fig. 9. Note we have 9 cells connected in series, (upper illustration), each cell gives 2 volts, in fact all cells give 2 volts, but the amperage or output varies according to the size and number of plates to each cell. Suppose in this instance, each cell is an 80 ampere hour capacity cell. In the **series** connection we would have 18 volts and 80 ampere hour output.

Fig. 10. If cells were connected is series parallel, with 3 cells in series and then parallel or multiple connection as shown, we would have at the terminals, the voltage of 3 cells, or 6 volts and the amperage of 3 cells, or 240 ampere-hour capacity.

Note 18-volts x 80-amp.=1,440 watt hours, and 6-volts x 240-amp.= 1,440 watt hours. Showing that the **total out-put** is the same, the only difference being the **rate** of out-put.

HART NO. 205-C—Rectifiers for Charging Single Batteries. Explaining How Storage Battery Cells can be Arranged to give Various Voltages.

*The solution **consists** of a concentrated solution of common baking soda in pure water.

Fig. 30. Straightening plates.

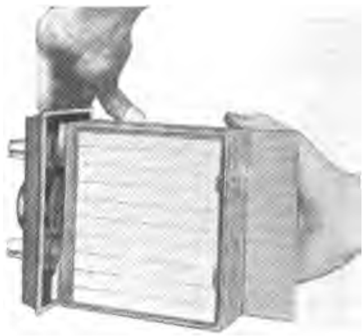

Fig. 31. Inserting separators.

The top construction shown in Fig. 1, chart 208-A is common to all modern types of "Exide" starting and lighting batteries.

There are three general types, differing in minor details which are clearly set forth in Figs. 19, 22 and 26.

Fig. 19 shows the bolted connection type, which always takes the double flange cover.

Fig. 22 shows the burned connection type with the double flange cover—(DC).

Fig. 26 shows the burned conection type with the single flange cover—(SC).

CHART NO. 205-E—Illustrations Explaining the Burned and Bolted Connectors. Single and Double Flange Tops of Battery Cells. Straightening Plates. Inserting Separators.

Exide illustrations are used as examples.

—continued from page 463.

After the connections are removed, unseal by heating a flat-bladed knife (a putty knife will answer) in a flame, and run it through the sealing compound close to the jar wall all the way around. This will loosen the compound, and the element with the cover on it can be lifted out of the jar.

If elements are difficult to remove, don't pull too hard—if they do not come—fill cell with boiling water, which will soften the whole cell, and plates will come out readily.

Taking element apart: After removing the cover, lay the element down with the plates on edge and slightly spreading the plates, withdraw the separators one at a time. The positive and negative groups can then be separated and the dismantling is complete.

How To Examine Plates.

Remove the group and examine plates by holding up side down and look down them and note if plates are warped or bulged out and if they press against separator, or if active material has worked between, thereby short-circuiting. Also see if separators are good.

If positive plates are not warped and separators are in good condition, yet battery will not hold charge, then the fault must be with the negative plates.

Examine negative plates, and see if the filler is bulged out and very porous or spongy and if active material has fallen out. At first glance you would hardly notice this, but examine carefully. If in this condition there is no need of putting in new separators, but put in new negative plates and separators, providing positive plates are good.

A battery with negative plates in poor condition will take a charge all right, the gravity test will be o. k. as will a voltage test, and have all the indications of a healthy battery, **yet will not hold up to capacity.** See also page 416.

When putting in new plates, be sure both are fully charged or discharged, or in same condition.

If negative plates are to be used again don't let them dry, but place the group in electrolyte or water—this will save time in charging after reassembling.

*How to Remove a Bad Plate.

Suppose you find that one or several of the positive plates are buckled or worn out, the best thing to do is to cut out the plate at the place where it is lead burned to the strap and a new one should be "lead burned" in its place. You will very seldom have to replace a negative plate, for they generally outlast two positive plates.

If a post is loose or in bad condition, it is advisable to have an entire new group of plates, either positive or negative as the case may be.

The positive plates should be examined particularly for washing out of material and buckling (warping). If the material has washed out on the surface to a depth below the base of the horizontal ribs, a new group should be substituted. If the plates are only slightly buckled, they can be replaced as they are, since this generally does no harm. If they are badly buckled, a new group should be substituted.

A buckled positive plate can be used again by cutting off outside rib about an inch from bottom on either end. See page 457, fig. 4 and note curve of plate when buckled. This causes a separator to be cut and shorts the plates.

****The negative plates are nearly always in good condition mechanically,** as they are not affected by abuse as readily as the positives. If the positives are buckled, the negatives will be also; but if in a charged condition, can be readily straightened as follows:

Place boards of suitable thickness between the plates and outside of the group and slowly apply a gradual pressure. This is best done in a vise, leaving the pile in the vise for some minutes during the operation to give the plates a chance to straighten without undue strain (fig. 30, chart 205-E).

If the battery has been badly abused, "starved" or neglected, the negatives may have shed material; in this case it is best to use a new group. If the negative material is very hard and not spongy, it is "sulphated," and particular care should be used that the subsequent charge is carried to maximum gravity.

The wood separators should be examined as to their physical condition—if soft and mushy and worn thin at several places—by all means change them, in fact, unless a battery is comparatively new, it is advisable to install new separators, whenever a cell is dismantled for repairs, since it is of vital importance in a battery to have the separators in good condition.

They should be kept in stock wet, preferably in water acidulated with electrolyte and when fitted, should extend about 1/8 in. over plates.

Perforated rubber sheets, when used are nearly always in condition to put back unless broken in handling. It is advisable to carry a small stock of these for emergencies.

The sediment in the bottom of the jars will rarely be found to have reached the plates, but whenever a cell is taken apart for any purpose, it is advisable to wash sediment out.

Sometimes impurities get into the electrolyte through carelessness or ignorance, but their detection is not practicable except by an expert chemist. As a precautionary measure, the use of new electrolyte of known purity is recommended when repairing.

Take a hydrometer reading of the old electrolyte before discarding, as this determines the proper gravity of the new electrolyte to be used in case the old plates are put back.

When the positive plates are badly disintegrated, it is usually a sign of foreign matter in the electrolyte, and in such a case it is safer to discard the negatives and separators as well, since they may hold some of the impurity and be the means of ruining the new positives in a short time.

Battery case: Unless there have been broken jars or abuse of some sort, the battery case will usually be found to be in good condition. If the case has become acid soaked and rotted, a new one should be

*These directions do not apply to any particular make of battery. We have used the "Exide" in many instances, to show relation of one part to another. **See foot note, page 446 and note how negative and positive plates are arranged. ‡See page 864D for "Cadmium Tests."

††Carrying gravity of acid too high will also cause negative filler to bulge out.

used. When the old case is to be used again, it should be soaked in a solution of baking soda and water. This will neutralize any acid and prolong the life of the wood. Rinse with water and allow to dry thoroughly. Repaint the case inside and out with **asphaltum** or other **acid proof paint.**

Reassembling Battery.

After the necessary repairs have been made, the battery should be reassembled as follows:

Wipe the posts with a piece of waste moistened with ammonia, rinse with water and dry thoroughly with clean waste.

Assembling elements: Slip the positive and negative groups together without the separators and place the cover in position, being sure not to omit the soft rubber washers under the cover.

Inserting separators: Place the groups on edge (fig. 31, chart 205-E) and insert the separators, **being sure that the flat side of the wood goes against the negative plate.** (Where rubber sheets are used (types PH and MH), place one against the grooved side of each wood separator before inserting.) When the separators are all in place count them to be sure none are missing, stand the element up again and tap the edges of the wood separators with a wood block until they project equally on each side of the plates.

***How to seal the battery:** You are now ready to seal up your battery. Heat the sealing compound—you dug out—in a small bucket and apply a little with a putty knife around the places where the cell cover touches the cell. Let this get hard, then put in a small amount at a time, but always wait until it has become hard before you add more. If you add the sealing compound too fast it would run down through the crack into the battery. When filled, throw the flame on the sealing compound and smooth out the rough places.

Connectors: First see that the posts and the eyes of the lead connectors are clean and bright. If the disconnecting has been carefully done, the posts and connectors will be in good condition and need only washing with ammonia, followed (when dry), by slight polishing with sand paper or scraping with a knife. Place the connectors over the posts, lightly tapping them to a firm seat, and burn the joint, using a burning outfit (chart 205-F), or, if nothing better is available, a soldering iron. Do not use any soldering acid or other flux.

Filling Cells with Electrolyte.

Fill the cells with new electrolyte until the level rises in the filling tubes, and be sure to replace and tighten the filling plugs before starting to charge.

The specific gravity of electrolyte to use will depend upon the condition of the plates.

If new elements are used, fill with 1.375 gravity for all types of exide batteries, except PH and MH, which take 1.330 gravity.

If old plates and new separators are used, fill with electrolyte 50 points (.050 sp. gr.) higher than the old electrolyte. When the old separators are put back, use the same gravity as the old electrolyte. The electrolyte must be of proper purity (pages 448-449).

If electrolyte of the desired gravity is not at hand, electrolyte of any higher gravity can be diluted with pure water. To mix electrolyte from strong sulphuric acid, see pages 448-449.

Putting Acid and Separators into a Repaired Battery.

If battery was repaired for a short circuit, put 1,250 acid into the cells that were repaired. The reason you put such a high acid in the cells is because the acid soaks into the new separators. It is hard to tell just what gravity of acid to put into the cell. The best is to put in 1.250 and start charging. The acid in a short time will drop to about 1.100 and then as the charge goes on, it will gradually rise until it becomes constant, that is, the acid reading will be, say 1.200 and at the end of another five hours charging it will still be 1.200. This shows that the cell is fully charged, but the acid gravity is not high enough. Add a stronger acid until the gravity shows 1.260.

If you only repair one cell of a 6-volt battery, the other two cells should be discharged with a lamp or two during the time you are repairing the cell. If you would not discharge these two cells, afterwards when you charge the whole battery, these two cells would get too much charge.

Why Gravity Sometimes Drops on Inserting New Separators.

When it is necessary to put in new separators, and a new solution, it will sometimes result that in charging this battery that the gravity of the solution will drop rather than rise. This is due to the following causes; the separators will consume a certain amount of the strength of the acid and as the charging process continues the separators will be absorbing the acid as fast as it is driven from the plates. If the battery was in a discharged state when new separators were put in, then the charging current would drive acid from the plates faster than could be absorbed by the separators and would raise the gravity of the solution instead of lowering it, but in most cases, you will find that the solution either drops or stays as it was. Charging does not have much effect in cases of this kind.

If the storage battery is in a charged state and a new solution be put into it, it will also be impossible to bring the specific gravity up by charging. It will stay as when put in or fall off slightly. This is because there is no lead sulphate on the plates for the electrical current to change back into an acid solution. In cases of this kind the original solution put in battery should show a gravity between 1.275 to 1,300.

**Charging after Repairing.

Do not start the charge until at least 12 hours after filling with electrolyte. This is to give the cells a chance to cool, and in very hot weather a longer stand may be necessary.

Charge at about one-half the normal charge rate, until the specific gravity and voltage show no rise over a period of 5 hours and all the cells are gassing freely. This will require at least 50 to 96 hours in case of new elements, while with old plates which are badly sulphated or have dried out, considerably more time may be necessary.

Take occasional temperature readings, and if the temperature reaches 110 degrees F., either lower the current rate or interrupt the charge.

*This does not apply to Exide only—in fact we have varied the directions, so as to apply in general, to different batteries as much as possible.

**Any of the cells which have not been torn down for repairs should be left out of the charging circuit for the first 30 hours, then connected, and whole battery brought up to a full charge.

When the charge is complete, adjust the electrolyte to the proper level, continuing the charge to allow the gassing to thoroughly mix the solution. Take a hydrometer reading on each cell and adjust the specific gravity to the proper point (1.270—1.300).

***Adjusting gravity:** If the adjustment necessary is slight, this may be accomplished by removing some of the solution and adding water or stronger electrolyte as required.

If the adjustment necessary **is considerable,** it will be found more convenient to empty out the solution and refill with electrolyte of specific gravity estimated to bring it right, allowing for the effect of the old solution held in the cells. A little experience will enable the operator to gauge this quite accurately.

After any adjustment, charge for some minutes to allow the gassing to thoroughly mix the solution before taking hydrometer readings.

If the temperature is far from normal, correct the hydrometer readings by adding one point (.001 sp. gr.) for each 3 degrees above and subtracting one point for each 3 degrees below 70 degrees F. (See fig. 12, chart 204).

Always wipe off the top and sides of battery with weak ammonia after adjusting electrolyte

Lead Burning.

The parts of a battery which must be burned together by melting the parts to be joined are the post-straps to the plates, connecting links to the post and terminals to the posts and lead terminals on the battery cables. **Methods for lead-burning are as follows:**

1—by **an electric arc.**
2—by **gas** or a combination of gases.
3—by a well tinned **soldering iron,** with pure lead as a solder.

The Electric Arc.

The electric arc method, consists of one terminal of a spare 6-volt battery connected to terminal to be burned on the battery being repaired. The clamp (C, fig. 36) is connected to the other terminal of the spare battery, or on one of the connectors of the adjoining cell, depending upon whether the battery is partially discharged or fully charged. In the latter case, 3 cells will give too much voltage. The number of cells should be sufficient to heat the carbon (CR) to at least a bright cherry red while it is in contact with the joint.

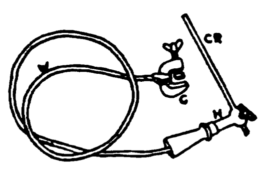

Fig. 36. An electric arc burning outfit.

To the end of cable (W) a carbon holder (H) should have a piece of carbon (CR) sharpened to a long point like a lead pencil and should project not more than 3″ from the holder. When contact is made at the terminal to be burned this completes the circuit and an "electric arc" is formed.

Although called the "arc burning outfit," more satisfactory results can be obtained by using the carbon after it becomes heated like a soldering iron, without actually drawing an arc.

The carbon should be cooled off occasionally by plunging it, carbon and all, into a pail of water. After being used for a short time, it will be found that the carbon will not heat properly, due to a film of scale formed on the surface. This should be cleaned off with a knife, or file, as occasion requires.

As in the case of flame burning, additional lead to make a flush joint should not be added until the metal of the pieces to be joined has melted. The carbon should be moved around to insure a solid joint at all points. The electric arc outfit can be secured of the Electric Storage Battery Co., Philadelphia, Pa.

Lead Burning With Gas.

Where there is considerable work to be done gas or a combination of gases should be used. On page 726 different methods are explained. In addition to using the flame for lead-burning it can be used for welding light metals.

Gases which can be used, other than stated on page 726, are hydrogen and oxygen, hydrogen and compressed air. The combination used most however, are those shown in No. 20 and 24, page 726. The illuminating gas and compressed air can be used but it does not give as intense or hot a flame as the No. 20 and 24.

To use gas it will be necessary to have the proper kind of lead-burning torch, also two valves for properly mixing the gases to control the size of flame, called the bench-block also rubber hose and regulators on the gas tanks—see page 726.

Soldering Iron.

In absence of a lead-burning outfit a fairly good job can be done by using a very hot, well tinned soldering iron, with pure lead as a solder. This however is not advised, only for temporary work.

Pointers on Lead-Burning.

Cleaning surfaces: In all lead burning, absolutely clean surfaces are essential to good workmanship. Lead is soft and very readily cleaned with a scraper or file. In the case of a battery which has had electrolyte in it, the surface to be burned should first be wiped with ammonia to neutralize the acid, then allowed to dry before scraping.

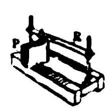
†**Before starting to burn,** the connector or terminal should be lightly tapped to a snug fit on the post. The top of post should be ⅛ inch below top of the connector to allow space for burning. If post is too long, remove connector and trim off post.

Method of burning: The top of the post should be melted first, then fused to connector, after which lead from a piece of burning strip can be run in until joint is flush.

Color of flame when using gas and air, should be a greenish color. If too much air, the color will be blue and gradually become invisible and is deficient in heating power.

FIG 11

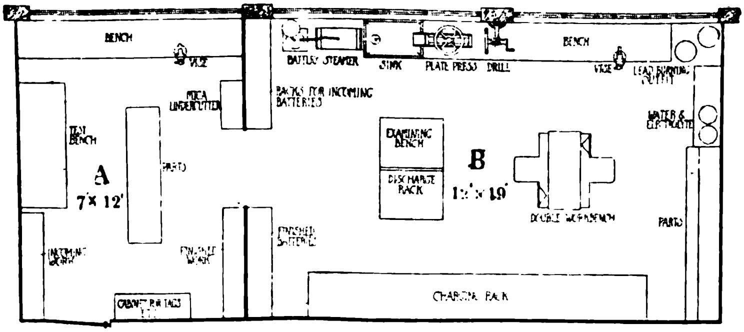
Phillips battery charging and testing clips—simply fit the charging wires with these clips and snap them over the battery terminals—price 25c. Illustration ½ size.



When burning-in new plates or a whole group of plates (P) to a plate strap, a burning-rack (R) to hold plates exactly correct distance apart is needed.

*Also termed, "balancing electrolyte", see page 864E, how to "adjust" or "balance" the electrolyte.

†**In order to avoid the possibility of an explosion of the gaseous mixture when using a flame near a battery**—place filling plugs in battery and cover entire battery with a wet cloth, pressing it down over vents of cells, except that part on which the burning operation is to be performed.



Lay out for Electrical Work.

B—Shows lay-out of room for battery work such as charging, putting in new plates, new separators, new jars, burning-in straps, discharging and testing. Room is 12'x19' and is a part of the "Service Station," as shown on page 616.

A—Shows lay-out of room for the electrical department for starting, lighting and ignition work, such as putting in new brushes, new windings, testing and repairing armatures (if the job is not too complex), undercut mica in commutator, recharge magneto magnets, put in new condensers in magnetos, timers and coils, regulate charging rate of generators, test and repair electric horns. All of which is explained in this book—see index.

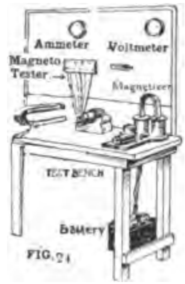


FIG. 24

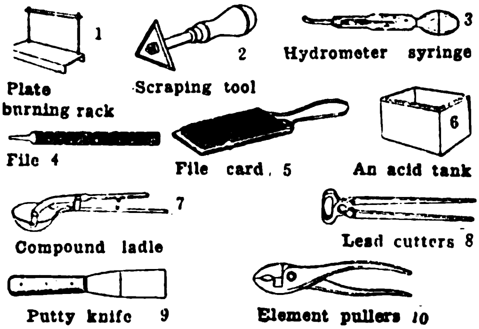
Supplies should be carried in the electric department, such as lamp bulbs, spark plugs, fuses, condensers, generator and motor brushes, timer points for Delco, Atwater Kent, Connecticut ignition timers. A **Wiring Diagram Book** for tracing circuits is very important. Electric testing instruments, see pages 737, 864H to J.



Tools for Battery Work.

1–**Plate-burning rack**—see page 471.
2–**Scraping tool** for cleaning parts to be burned.
3–**Hydrometer syringe** for testing and mixing electrolyte—(pages 452, 454).
4–**File for cleaning lead** before burning, 10".
5–**File card** for cleaning lead from file.
6–**An acid tank**, lead lined for mixing acid, storing and soaking separators 24"x36"x24". **Separators when new are usually dry and should be soaked in a weak solution of electrolyte before using.**
7–**Compound ladle** for melting sealing compound.
8–**Lead cutters** for cutting excess lead and for cutting post straps to necessary size.
9–**Putty knife** for scraping sealing compound.
10–**Element pullers** or regular gas pliers.
Rubber gloves (not illustrated).
Thermometer for determining temperature of electrolyte in cells (see page 450).
Lead funnel for filling batteries with electrolyte.

Supplies of Battery Work.

Compound for sealing jars and surrounding jars. This can be made of gum asphaltum 50 per cent, paraffine wax 25 per cent, and resin 25 per cent, melted together. Battery stations usually buy this compound in bulk.

Solution for making battery box acid proof, see page 473. This can be purchased at battery supply houses.

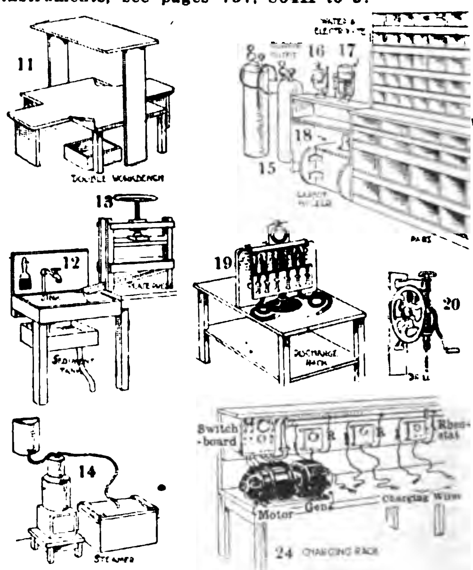
Electrolyte at 1.300 sp. gr. test should be kept in a closed stone or glass vessel. Electrolyte is sold by manufacturers, see also, **pages** 448-449. Electrolyte is mixed with water to density required when using.

Distilled water. A supply should be kept on hand for battery use—see pages 458, 455, 709.

Extra battery connectors should also be kept on hand as well as other connections and parts such as extra **jars, covers, vents, separators,** etc.

Pure lead (10 lb.) for burning connections together. **A 10 lb. bundle of antimony** and lead bars for burning to straps.

Glass tube for testing the acid level, see page 455.
Volt-ammeter with a scale 0-30 volts and 0-3-30 amperes is indespensible to the battery repairman, see pages 414-416-398-453-864H.
Cadmium volt-meter—see page 864I.



Equipment for Battery Work.

11–**Work bench** and seats.
12–**Sink** for washing plates etc.
13–**Plate press.** In discharged negative plates **the active material is bulged out and must be pressed back flush with the grids. As the acid is pressed from plates it flows into lead coated troughs. Length of jaw 19".**
14–**Battery steamer for softening the sealing compound so it can be opened—see also, fig. 23, page 473.**
15–**Lead burning outfit—see page 471, 726.**
16–**Distilled water (see pages 455, 458, 709).**
17–**Electrolyte** (see **pages 448, 449**).
18–**Carboy of acid.**
19–**Battery discharging outfit** for discharging battery after assembling **(page 474).**
20–**Post drill to drill top of connectors—see page** 463, "to remove connectors".
24–**Motor-generator battery charging outfit.** A rectifier or other methods could be used—see pages 864K, 864L.

CHART NO. 205-F—Battery Repairmans Outfit. (Motor Age by Mr. B. M. Ikert).

Miscellaneous Storage Battery Repair Information.

Corrosion of the terminals or other parts of the connectors, should be prevented by coating them with vaseline or petroleum jelly. Sometimes they get so badly corroded that it is almost impossible to unscrew the terminals, and greasing them in this way will prevent recurrences of such trouble.

When overhauling a battery, it is a good plan to put all the connectors, terminals and other removable pieces at the top in a strong solution of soda and hot water and let them stay in it for about an hour, so that the solution will have plenty of time to clean them thoroughly. Then put on the vaseline and no more corrosion should appear. In the first place, it is usually the result of overfilling the jars or spilling the solution, which in time acts upon the lead and brass terminals.

A Cracked Battery Jar.

Never attempt to repair a cracked or broken battery jar, as this is impossible. When the jars get in this condition they must be discarded as useless.

It is not very much trouble to remove any cell from a battery because the makers have seen to this point. To take apart the connectors on a Willard battery, for instance, the procedure is to drill a ¾ in. hole in the end of the connector, directly over the post. This hole should be drilled with any form of drill and about two-thirds through the connector, when the latter will come off readily. The connectors have to be burned back on and more lead used to fill up the drilled out hole.

To remove a cell from an Exide battery, the top nuts and connections must first be taken off, the nuts unscrewing in the regular manner.

Celluloid jars can be repaired by making a cement of celluloid and acetone. Dissolve the celluloid in acid until it is gummy then clean seams and coat.

Cracked Compound.

Sometimes the tar composition material that is on top of the cells cracks, and very often these become serious points of leakage of the cell solution. The best and simplest way to remedy them is to seal them together with a hot iron such as an old cold chisel or similar tool. Press the hot iron on the sides of the crack and gradually work them together until the hole is sealed over. If more of the tar material is needed, a big lump of it can be secured from a battery service station.

To Make a Battery Box Acid Proof.

Use 6 parts of wood tar and 12 parts resin, melt them together in an iron kettle, after which stir in eight parts of finely powdered brick dust. The surface to be covered must be thoroughly cleaned and dried before painting with this preparation, which should first be warmed.

Spilled Electrolyte.

If there is evidence that electrolyte has been spilled from the cells, use electrolyte of 1.250 specific gravity instead of water to make up the loss.

After adding water, replace and tighten filling plugs by turning to the right and give the battery a charge at the proper rate for the type of battery as given in the table (page 467).

Never add electrolyte to a cell after the gravity has been adjusted to the proper point, unless to replace actual loss by spilling.

Fig. 24.—Crating a battery for shipment; note shape in illustration. Inside dia. should be 2" larger than battery and stuffed with excelsior. Label "handle with care—ACID."

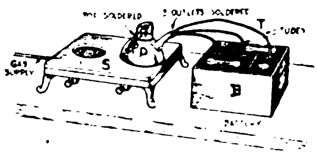


Fig. 23 — A home made steam generator for softening the composition so that battery top may easily be removed. Consists of kettle (P), gas stove (S) and tubes (T). Steam is generated and passed into cells. The acid should first be removed with syringe.

*Prices to Charge and Addresses, Etc.

Price for charging a starting and lighting battery which includes testing ....50c to $1.25

6 volt type	$..50
12 volt type	.75
16 volt type	.85
18 volt type	1.00
24 volt type	1.25

These prices do not include changing of batteries. All changes not requiring more than 15 min. 25c. Batteries requiring more time to take out and replace, will be charged for at regular labor rates.

Price per day for rental of a battery in your car while your battery is being charged, 10c to 25c.

Starter rentals will not be installed until generating system on car has been tested and we are assured that battery will receive proper charge while car is in use. A deposit to cover rental batteries is required.

Price for testing the electric system, other than disconnecting and connecting your battetry, per minute ....1c to 2c

Price for repair work, per hour ....60c to $1.00

Notice—Storage batteries left over 30 days will become our property and will be junked without recourse.

The above is taken from a printed placard on the wall of a leading storage battery repair shop.

Where to Obtain Supplies.

It is best to order plates and parts of the manufacturer of the battery. Names of some of the concerns who handle supplies are:

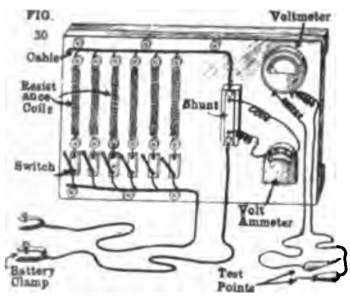
General Storage Battery Co., St. Louis, Mo. (supplies and parts of all kinds); **Meder Staudt Co.** (supplies in general), 1904 Broadway, N. Y.; **Storage Battery Supply Co.** (supplies in general), 239 E. 27th St., New York.

Address of Storage Battery Mnfgrs.

General Storage Battery Co., St. Louis; **Witherbee**—Meder Staudt Co., New York, N. Y.; **Exide**—Electric Storage Battery Co., Philadelphia, Pa.; **U. S. L.**—United States Light and Heating Corp., Niagara Falls, N. Y.; **L. B. A.**—Willard Storage Battery Co., Cleveland, Ohio; **Detroit**—Detroit Storage Battery Co., Detroit, Mich.

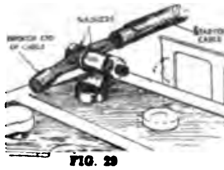
*Prices vary in different sections of the country. This is an example of prices charged by a concern in the West. See page 709 for a home made water still.

Fig. 30. A discharge board for discharging a storage battery at any desired rate is made with a number of coils of resistance wire, any one or more of which may be thrown into the circuit by means of individual knife switches at the base of each coil. The coils vary in size from stove-pipe wire to heavy telephone wire and that part of the board back of the coils should be covered with asbestos as the coils get very hot.



An ammeter and a shunt register the discharge, which may be varied by cutting in the different coils.

A voltmeter with test points is attached to the board and this is used for checking up the voltage of the individual cells at short intervals. The heavy leads may be made from old leads or cables from a car.



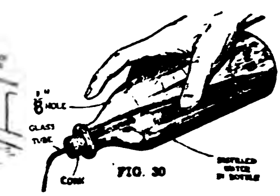


Fig. 29. Method of making a temporary battery terminal.

Fig. 3. For refilling battery with distilled water. Note ⅛" drilled vent hole in bottle. Glass or quill can be used for spout. See page 709 for a home made water still.

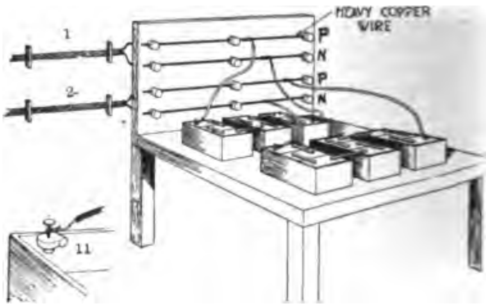

Fig. 11—A quick connection can be made from one battery to another by lightly driving a tack into terminals and using No. 18 steel wire. If an over-charge be applied—steel wire will heat and break.

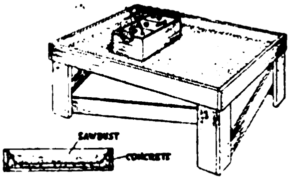
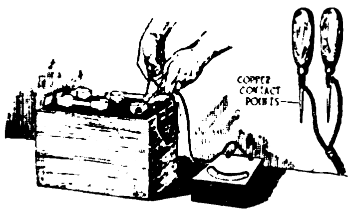
Fig. 13—Simple method of connecting many individual batteries to one pair of supply wires. P and N are large bare wires. 1 and 2 are separate circuits. Smaller leads to individual batteries can be made. (Motor World.)



A special bench with concrete basin filled with sawdust renders battery work cleaner. The sawdust absorbs the acid.



Voltmeter and copper contact points for testing voltage of different cells

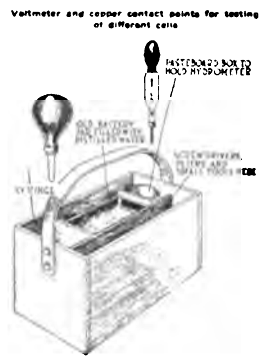


Fig. 20A.—Battery service kit: A rectangular box is divided into four compartments, as shown. One contains the hydrometer, in a cylindrical pasteboard box for testing; the second contains distilled water, in an old battery jar for replenishing water; a third holds a syringe for placing the water in the battery. The fourth space runs the entire length of the box, and is used for miscellaneous tools, such as screwdriver, pliers, meter, etc.

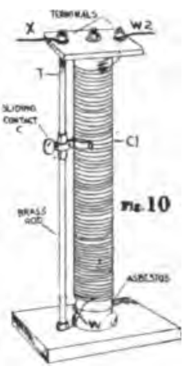
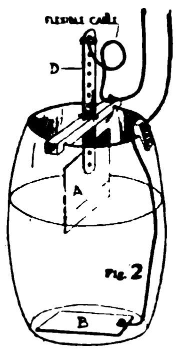
Principle of a Rheostat or Resistance.‡

A rheostat is a device for absorbing some of the electrical pressure. In order to make current flow through a conductor, it is necessary to apply electrical pressure (voltage). The greater the pressure more current will flow.

For example—suppose you desired to charge a 6-volt storage battery from a 110 volt circuit. It would be necessary to absorb approximately 104 volts in some sort of **resistance** or **rheostat. (see also page 464.)**





This resistance could be lamps as per page 460; iron wire per fig. 10; salt water per fig. 2.

***Iron wire rheostat:** Iron wire offers resistance to flow of current, therefore by using say— about $\frac{1}{16}$" dia. and wrapping it around an insulated cylinder, as porcelain or stone, and connect wire from 110 volt circuit to (X, fig. 10), the current would then pass down sliding contact rod (C). If one terminal of battery was connected at (W2) and other battery terminal to other connection of 110 volt line—this would form a circuit.

Now by moving **sliding contact (C) down, more resistance** is thrown into the circuit; by moving it up, **less resistance will be** in the circuit. This is the principle of a **rheostat** and is similar to "resistance units" shown on **page 464.**

A stove pipe, wrapped with asbestos and iron wire over it has been used.

Water rheostat; another way is to partially fill a 5 gal. stone jar with salt water (fig. 2). With one metal contact (B) in the bottom and the other (A), which is a sheet immersed more or less in the barrel. By movement of (D), the nearer plates are together—less the resistance. Further apart they are—more resistance, see pages 463 and 209.

CHART NO. 205G—Miscellaneous Battery Repair Devices. Principle of a Rheostat. (Motor World.) See also pages 424, 410, 414 and 864I for "Cadmium tests."

*Note that "direct" current is used and positive pole of current supply must connect with positive pole of battery. ‡See pages 209 and 463 for meaning of resistance.

Fig. 1.

Fig. 2.

Fig. 2—Showing positive and negative plates of the A-4 Edison cell assembled together, but removed from the container.

Fig. 3—Type A-4 Edison cell, showing the positive and negative plates in the container, and also the removed cover with openings. The retaining jar is made of sheet steel and electroplated with nickel.

The Edison Storage Battery.

The plates in the Edison battery are made of nickel and iron, the former in the form of a hydrate and the latter as an oxide.

The electrolyte is a solution of potassium hydrate (potash).

The positive plates consist of steel grids, which are nickel-plated; they are in the form of nets of 30 tubes per grid, each of which is filled with active material, the latter being composed of pure metallic nickel in the form of leaves or flakes. The pure nickel flake is produced by an electrochemical process.

The negative plates are composed of 24 flat rectangular pockets, which are supported in three horizontal rows in nickel plated steel grids. These pockets are also formed out of thin nickel-plated steel and they are full of perforations. The active material in the pockets forming the negative element of the battery is oxide of iron.

Voltage—each cell delivers approximately 1.2 volts. Therefore 4 cells would be required to give six volts instead of the usual 3.

The advantage claimed by the makers is in the greater amperage. For instance, the claim is that with five of their cells, weighing less than three cells, the amperage, or quantity of current the battery will deliver will be twice as much as the three cell battery.

It is stated that the reason the Edison battery is not used for starting motor purposes is due to the fact that its internal construction is such that it cannot deliver the high discharge amperage suddenly, as required. It is capable of delivering a low amperage for a very long period, however.

The G. V. Electric Truck

is illustrated below and on pages 476 and 478.

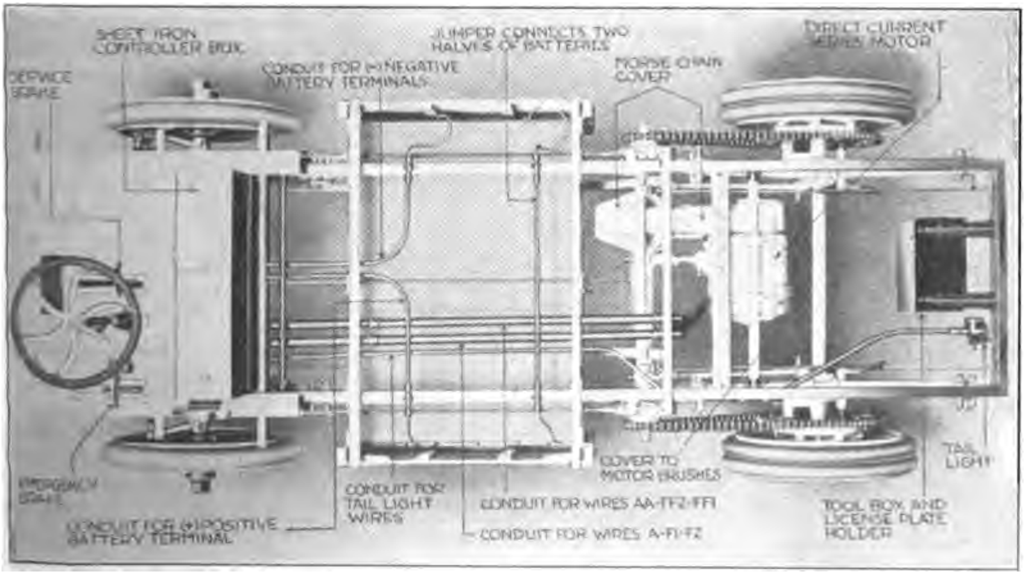


Fig. 1: Top view of G. V. 2 ton electric truck. The G. V. truck is made in 6 sizes; 1000 pound wagon is made with worm or chain drive; 2000 pound, chain driven; 2 and 3½ and 5 ton trucks are chain driven.

CHART NO. 206—The Edison Storage Battery (Edison Co., Orange, N. J.) **The G. V. Electric Truck** (General Vehicle Co., Long Island City, N. Y.)

Specifications.

Carrying capacity 2 tons; speed, miles per hour 9; mileage travel (approximately) on one charge 45; number of batteries 42; amperage (approximately) in starting 75 to 80; amperage when running 35; weight of truck including batteries 6,395 pounds; weight without batteries 4,050 pounds; price (chassis) $3,000; wheel base 112½"; track or tread 61"; overall length 167"; tires (solid) front 36x4, rear 36x3 dual.

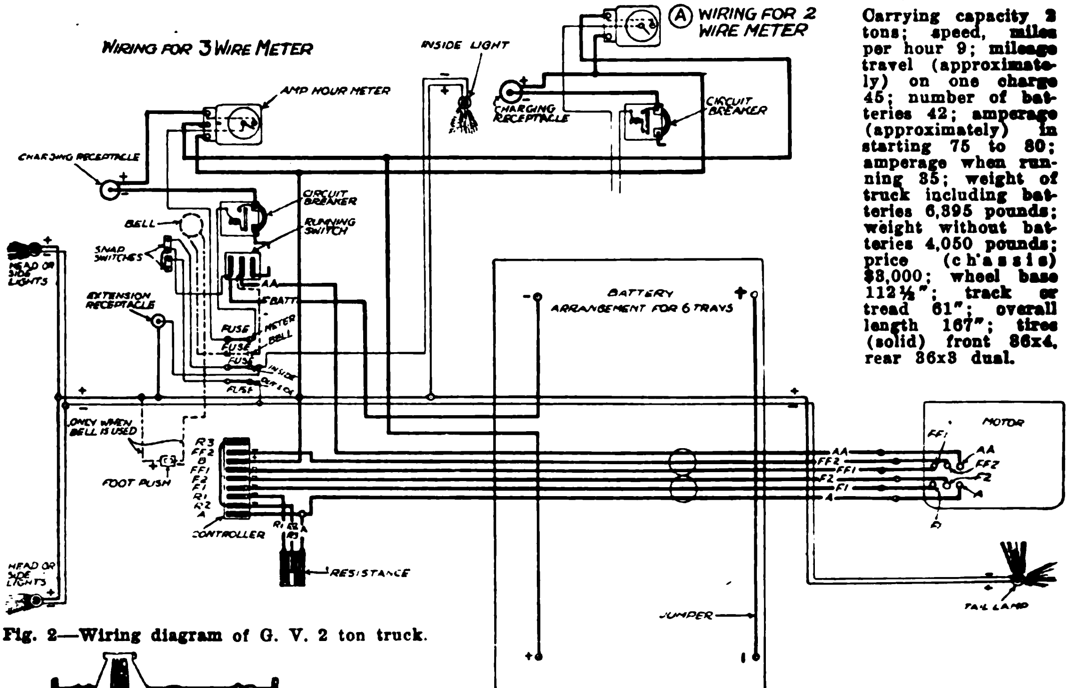

Fig. 2—Wiring diagram of G. V. 2 ton truck.

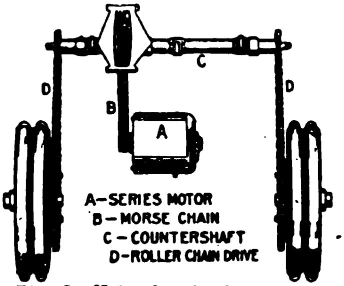

Fig. 3—Note the simplicity of the drive system—see also page 475

Explanation of Parts of Electric Truck.

The controller box is placed in front convenient to the driver (see figs. 1 page 475, and 4). It contains the controller, resistance unit, fuse block switches, etc. The current is disconnected by the switch (fig. 4) which is a 3 way running switch and is thrown to the left when battery is being charged, to the center when current is off and to the right when running.

Fig. 4; Controller box. A—sheet steel controller box; B—controller handle; C—three way switch; D—lamp circuit fuses; E—plug for portable lamp; R—resistance.

When charging battery—connection is made with "charging receptacle" (fig. 2) from an outside source of electric supply. In case the current charging battery should fail for any reason the circuit breaker (fig. 2) will disconnect so that current from battery would not flow back.

The ampere hour meter (fig. 2) shows the amount of current taken from battery when running.

When charging, a compensating shunt is used, so that the meter runs approximately 15% slow. The Sangamo Electric Co., Springfield, Ill., manufacture the meter used on this truck.

HART NO. 207—Electric Truck (General Vehicle Co.'s 2 Ton Truck as an Example).

orse power of motor at 84 volts and 40 amperes is approximately 4 h. p. Starting cold, this motor will run 100% rerload for one half hour and 200% overload for 10 min.

'iring diagram above shows connections to be used for either differential shunted "three-wire" ampere-hour meter ' "two-wire" ampere-hour meter equipped with variable resistor element.

INSTRUCTION No. 33.

*THE ELECTRIC VEHICLE: Electric Truck; Dual Power Cars; Gas and Electric. Electric Brake. Electric Gear Shift. Magnetic Latch. Couple-Gear Gas-Electric Truck. Four Wheel Drive. The Entz Owen Magnetic Electric Transmission of Power. Prest-O-Vacuum Brake. The Solenoid.

The Electric Vehicle.

Although this book deals principally with gasoline engine driven cars, a few words relative to the construction and battery connections of an electric vehicle will be given.

Electric vehicles are used to a great extent for pleasure cars and trucks. The objections to an electric pleasure car is the recharging of the storage batteries which prevents long country runs. The electric vehicle is a very simple proposition compared with the power plant of a gasoline vehicle and for city truck use is considered very serviceable, especially where a charging plant is convenient.

The electric vehicle is made up of three parts; a body; the chassis; and the motor, controller and batteries, or the power plant.

The power plant; an electric motor (series wound) and similar in many respects to the starting motor described in Instruction 26, is mounted to the frame, illustration chart 207 shows method of mounting the motor and driving by a chain, oftentimes a propeller shaft drive is used.

Average h. p. of motor for the electric pleasure vehicle is about 4. On trucks it varies as follows; ½ ton truck 3 h. p.; and 1 ton, 4; 2 ton, 5; 3 ton. 7; 5 ton; 10.

Batteries: It has become standard practice on pleasure vehicles to divide the battery, placing approximately half of the cells at the front end of the chassis on a rack level with the frame, and covering them with a wooden hood extending out in front of the dash or forward end of the body proper. The rest of the cells are placed in a similar position at the rear, where they are covered with a wooden boot. The hood and boot are either hinged or removable.

An example of placing batteries on a truck is shown in chart 207.

There are usually, 42 or 44 cells. Each cell gives two volts, therefore the voltage with all connected in series would be 84 or 88 volts.

On the truck shown in chart 207, there are six trays of seven 3-cell batteries. Therefore 42 cells, or 84 volts in series.

The amperage of the cells used on pleasure cars are usually from about 150 to 180 ampere hour.

Controller.

The controller in an electric vehicle performs practically the same function as the change speed mechanism in a gasoline car. It controls the flow of current to the motor, and so regulates the speed of the vehicle and the construction is similar to those used on street cars.

An electric vehicle, to maintain its rate of speed is dependent on the voltage and current output of the battery, as the energy required for maintaining this speed is measured in watts; i. e., voltage × amperes equal watts.

The nearer normal voltage of the battery under working condition, the nearer the maximum speed of the car. This is due to the fact that a motor in any given vehicle, is so constructed that for the armature to make its complete number of revolutions per minute a given voltage is required. This speed can be varied by introducing into the circuit a suitable amount of resistance. The effect being the lowering of the voltage delivered to the motor. As a normal voltage is required to maintain normal speed of the motor, it follows that the lowering of the voltage will be a corresponding lowering of the vehicle speed. This introduction of a variable resistance, together with the relative positions of the field windings of the motor, is accomplished through what is termed the controller. The changes in the various positions or speeds being accomplished without any break in the circuit, giving a steady gradual increase or decrease. In the General Vehicle Co.'s truck, page 476, the speeds (five forward and two reverse) are controlled by varying the resistance and in changing the position of the field windings (see page 478).

Amperes in Starting and Running.

When first starting the motor from a stand-still on a pleasure vehicle, the quantity of current used is about 50 to 60 amperes, after being in motion and on a level it will drop to about 18 to 25 amperes.

On a truck, say, ½ ton capacity, the amperage would probably go to 75 to 80 when starting and about 35 when running on a level.

The usual ampere-hour capacity of batteries for trucks range from 160 to 227 or more ampere-hours. The number of cells being 42 to 44. The horse power of the electric motor is usually 8 to 10 h. p.

The 42 or 44 cell battery will have the same ampere-hour capacity as a single cell, but of course the watt hour capacity increases in proportion to the increase in the number of cells and voltage.

Mileage and Speed.

The speed depends on the voltage or pressure.

The number of miles an electric vehicle will run depends on the size of the cells and amperage output (amperage means quantity), the larger the cell the more quantity of current it will deliver, but the pressure or voltage always remains the same, whether large or small

*If the battery gives 150 amperes for one hour, or one ampere for 150 hours, then it is called a 150 ampere hour battery.

If the motor on an electric vehicle requires, say 25 amperes per hour and your battery was a 150 ampere hour battery, then you could run your motor steadily for 6 hours and if your speed was 15 miles per hour you could make 90 miles—providing you were running on a perfectly level floor, but when you come to grades your motor will require more quantity of current or more amperage for a few minutes, or when starting off on a grade the motor will pull considerably more current from the battery. **Therefore the mileage is governed by the size of the cells and the current consumption.** A great deal also depends upon the driver, in how he uses his control as to current consumption.

Understand, the voltage of the vehicle battery when say, all 42 cells are connected in series, with motor, would give 84 volts Therefore if there was 15 ampere draw at 84 volt pressure—by multiplying the voltage and amperage together (15x84) we would get 1260 watts. 746 watts equal one horse power. A kilowatt is 1000 watts.

*Figures not accurate—used only as an example. There is a graduated loss governed by rate of discharge, see page 441.

A rectifier or charging plant for charging electric vehicle batteries should be one which will give at least 30 amperes and 110 volts or 3 kilowatts (a kilowatt is a 1000 watts.)

—continued from page 476.

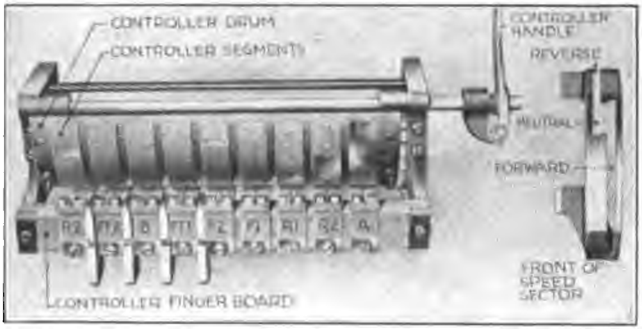

Fig. 4A: Controller—note connections of fingers, refers to diagram fig. 6.

The Controller

is used to make connections for the different speeds. By referring to fig. 4A, note the movement of lever for the 5 speeds forward and 2 speeds reverse.

The controller is of the "constant torque" type and batteries are connected in series at all times. The various speeds are obtained by cutting out or in resistance (cast iron) and also by making "field" connections of motor as explained below.

Controller Connections.

By referring to fig. 4A and diagrams fig. 6 and 7 the connections from controller to resistance and field circuits can be traced.

R1, R2, R3—mean resistance; R1 all resistance is in circuit; R3 about one half is in; R2 about one third is in—see fig. 7.

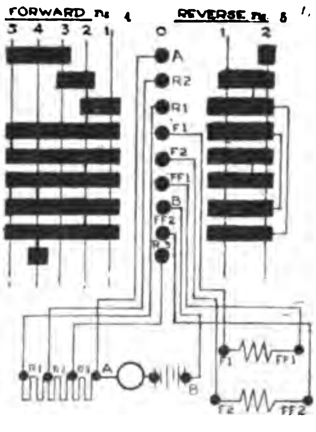

Fig. 6—controller connections: O—is off or neutral position. Black dots refer to controller fingers. Black squares refer to controller copper segments. The 5 speeds forward and 2 speeds reverse are shown.

F1 and F2 is one set of 3 field windings; FF1 and FF2 second set and are connected in series. The two windings are connected in series on speeds 1-2-3-4 and in parallel on 5th speed.

A1 and AA are to armature brushes; there are two brush holders with three brushes each, on motor.

In fig. 6, the letter "O" is the neutral or "off" position of controller, and the black dots refer to controller fingers.

Forward Speeds.

First speed; see fig. 7—(1 forward); both fields are in series and all resistance (R1) is in the circuit. This is the slowest speed.

Second speed; see fig. 7—(2 forward); both fields are in series and part of resistance is cut out (R2).

Third speed; see fig. 7—(3 forward); both fields are in series and all resistance cut out.

Fourth speed; see fig. 7—(4 forward); resistance (R3) is shunted across the series field.

Fifth speed; see fig 7—(5 forward); fields are in parallel; all resistance cut out.

The forward speeds are divided approximately equal, each notch of the controller being an increase of approximately 20 per cent in speed.

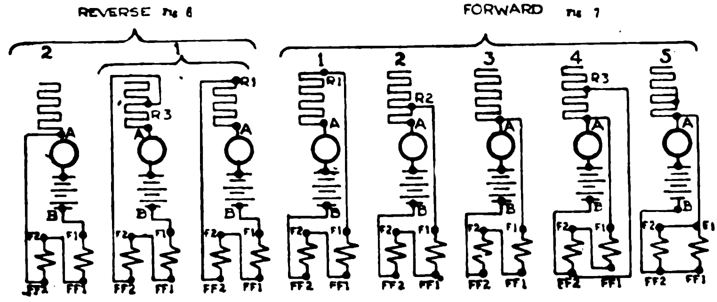

Fig. 7—Illustrating the resistance connections R1, R2, R3 and field connections F1 and F2 and FF1 and FF2. A—is armature brush connections; B—battery connections.

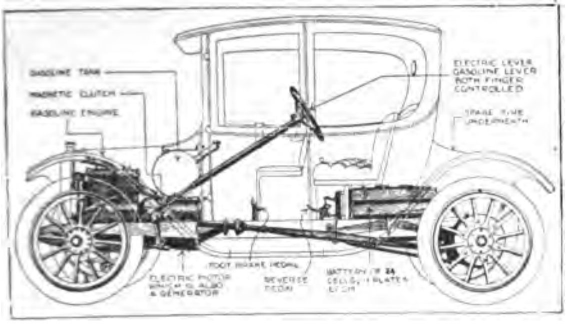
Reverse Speeds.

Reverse speeds are the same connections as second and third forward, but passing through first speed to prevent heavy rush of current. The direction of flow of current is changed which reverses the rotation of armature.

For resistance, cast iron is used.



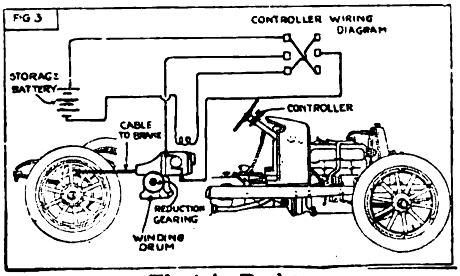
Woods Gas-Electric Car.

The Woods dual power car: The power plant consists of a small gasoline engine and an electric motor-generator combined into one unit, as illustrated, and mounted on a three point suspension. The movement of a finger lever on the steering wheel connects the engine to the electric motor-generator, which cranks the engine and develops power which is transmitted through the armature shaft of the electric motor and propeller shaft, direct to the rear axle.

The car starts as an electric, by a simple movement of a finger controlled lever on the steering wheel, which operates the means for connecting the battery to the motor and increasing the speed; as the lever is advanced.

At any advanced position of the electric lever the first movement of the—finger controlled gasoline lever—instantly starts the gasoline motor. As this lever is moved forward it causes the car to be operated more on the gas, and at a certain point it will run as a straight gasoline car neither charging nor discharging the battery. With a slight variation of the relative position of the two levers on the steering wheel, the battery may be either charged or discharged at will on any speed from ten miles an hour up to twenty-eight or thirty miles an hour. Electricity is generated and stored in the battery while the car is running.

At any speed above six miles per hour, dynamic breaking may be effected by retarding the electric lever. This causes the electric motor to run as an electric generator driven by the gasoline motor or by the momentum of the car. The power thus generated is used for charging the battery. The same effect may be obtained by a simple movement of the foot brake pedal, which also acts as a mechanical brake below six miles per hour. (Woods Electric Vehicle Co., Chicago Illinois).



Electric Brake.

The Hartford braking motor is shown with reduction gearing. Armature shaft carries a worm gear which drives at a reduction of 100 to 1. This worm gear in turn operates a drum through an internal gear at a reduction of 4 to 1, giving a total reduction of 400 to 1. A steel brake pulling cable which is wound on the drum, transmits the pull of motor to brake mechanism.

The controller (CL) is moved by degrees which applies brake gradually; or suddenly if moved to extreme limit.

The point of decreased speed before coming to a full stop is illustrated by the fact that a car, moving at the rate of 50 miles an hour, or 73-1/3 feet a second, can within 35 feet, or in one-half second's time, be slowed down to 15 miles an hour or 22 feet a second, and brought to a dead stop within the next 10 feet.

Current required is 40 amperes for 2/5ths. of a second and a pressure of 6 volts.

Prest-O-Vacuum Brake.

By utilizing the suction in the intake manifeld to exhaust the air from a cylinder (B) carrying a piston, the piston is forced to move, and in its motion applies the brakes through the usual braking system. The amount the brakes are applied depends, of course, upon the suction of the cylinder, and this is controlled by the driver through a throttle valve operated either by a pedal or hand lever.

Fig. 3 shows the general layout of the system when installed on a car. It will be noted that the forward end of the suction tube, is attached to the intake manifold at its junction (1) with the carburetor pipe, this being the point of most constant suction. From here it leads to the throttle valve (O) located convenient to the driver's foot.

The principle is similar to the air-brake cylinder used on railway trains, having a pressed steel shell, cast steel head, and carrying a pressed steel piston with leather packing. This piston has a diameter of 7 in., an area of 38½ sq. in. and a stroke of 4 in., the entire braking cylinder assembly weighing about 10 lbs.

The suction in the manifold (I) varies from 8 to 12 lbs. per sq. in. When the throttle valve (O) is opened wide, at least 10 lbs. per sq. in. suction is applied to the piston in the braking cylinder. Hence, the area of the piston being 38½ sq. in., a suction, or, to be more exact, a pressure, of 10 times 38½ or 385 lbs., is applied to the piston.

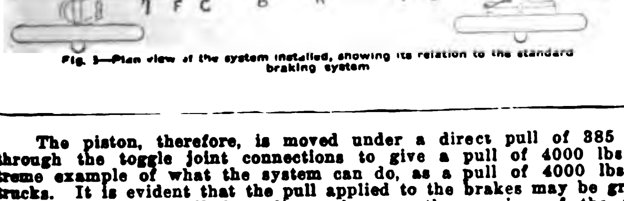


Fig. 3—Plan view of the system installed, showing its relation to the standard braking system

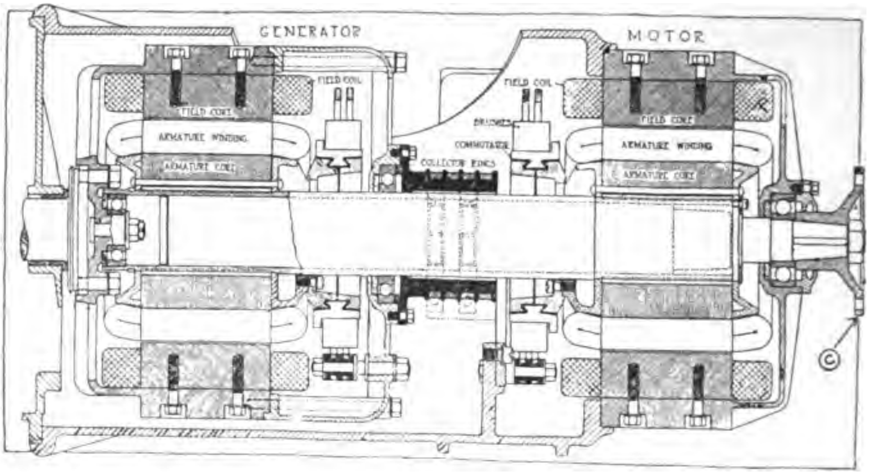
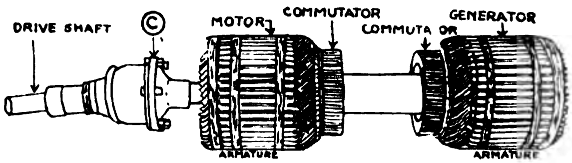
The piston, therefore, is moved under a direct pull of 385 lbs., and this in turn is compounded through the toggle joint connections to give a pull of 4000 lbs. on the brake rods. This is an extreme example of what the system can do, as a pull of 4000 lbs. is seldom required, unless on large trucks. It is evident that the pull applied to the brakes may be graded from 0 to 4000 lbs. at the option of the driver, the pull depending only upon the opening of the throttle valve. (Prest-O-Lite Co., Indianapolis Indiana, are the manufacturers.)

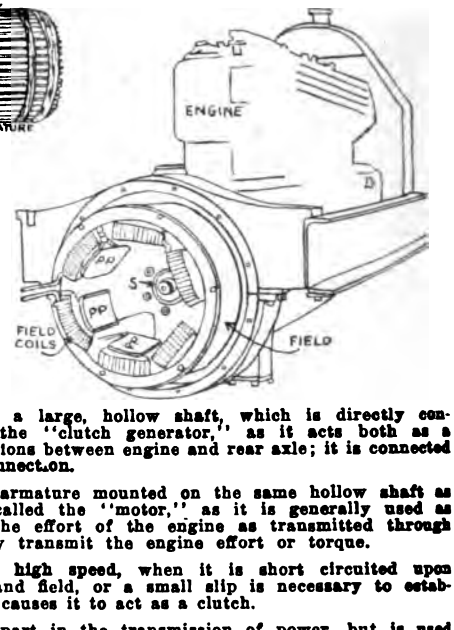
CHART NO. 207-B—Woods Dual Power Car. Hartford Electric Brake. Prest-O-Vacuum Brake.



Section through Owen-Entz electric transmission. Generator field cores and coils form the gasoline engine flywheel and the collector rings shown are for the purpose of connecting the field current of the generator tr the various circuits. The brushes of the generator revolve with the field. The two armatures are identical and both are keyed to the hollow shaft which is attached to the propeller shaft and has no connection with the gasoline engine

Electric Transmission.





Above—Armature of motor and generator attached to the propeller shaft as on the Owen magnetic car.

Right—Field coils, etc., of the electric transmission system forming the flywheel of the gasoline engine as mounted on the Owen magnetic car.

Explanation.

In place of the fly wheel, clutch, gearset, starting and lighting system and their auxiliary parts, two direct current dynamo machines and a drum controller have been substituted.

Clutch generator. One of the dynamo machines has its field magnet frame directly connected to the engine crankshaft, taking the place of the ordinary flywheel. The armature of this machine is mounted on a large, hollow shaft, which is directly connected to the propeller shaft. This machine is called the "clutch generator," as it acts both as a clutch and a generator. There is no mechanical connections between engine and rear axle; **it is connected through an "air gap" which is entirely a magnetic connection.**

The motor. The second dynamo machine has its armature mounted on the same hollow shaft as the first, and its field magnets are stationary; it is called the "motor," as it is generally used as a motor to help drive the propeller shaft, and boost the effort of the engine as transmitted through the clutch generator, which, like any clutch, can only transmit the engine effort or torque.

The clutch generator is used as a clutch alone, on the **high speed,** when it is short circuited upon itself, and a small speed difference between armature and field, or a small slip is necessary to establish the current in its windings which energizes it and causes it to act as a clutch.

On the **high speed** position the **motor** plays no part in the transmission of power, but is used as a charging generator for the storage battery, which later is used for cranking the engine and for the electric lights.

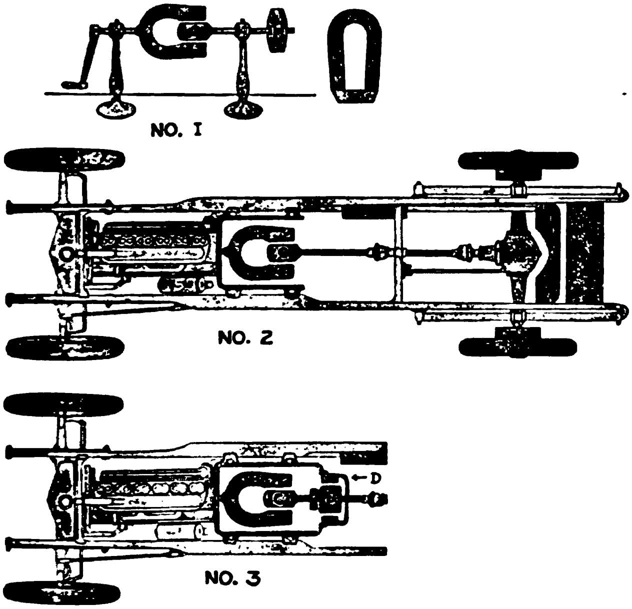
Electric motor aids propulsion. On all other power control positions but the **high, the motor** helps turn the propeller shaft, by taking current from the clutch generator in which circuit it is included. At these times the slip in the clutch generator is greater than needed to energize it as a clutch, and the **additional slip produces the current required for the motor,** which it utilizes for giving additional turning effort to the propeller shaft.

The different graduations of speed and torque are controlled by the relative strength of the generator and motor field. The weaker the generator field compared to the motor field the greater the slip and the more electrical energy goes to the motor for producing greater torque.

Besides the positions of power control, there is a neutral position in which the clutching effect is cut out, but the motor is so connected through a resistance as to act as an electric brake, in which case it becomes a generator, taking power to drive it, and so braking the car.

This brake is most effective when the speed is highest and is ineffective below 15 m. p. h.; **it will** hold the car on any mountain grade to 20 m.p.h. without wear of any parts and can be **applied with** the car going 60 m. p. h. It cannot hold the wheels and there is little danger of skidding, as the braking effort disappears at speeds below 15 m.p.h. (Automobile).

CHART NO. 207-C—The Entz System of Electric Power Transmission as Applied to the Owen Magnetic Car—continued on next page.



Elementary Principle.

Illustration No. 1—A. Magnet with keeper familiar to everyone.

B. Magnet and pedestal with hand crank to revolve it.

C. Piece of steel on pedestal placed within magnet on same line of travel, it will be apparent that as the magnet is revolved by turning the crank it will attract the piece of steel which will revolve with it.

Illustration No. 2—B is now revolved by gasoline engine instead of hand crank, taking the place of the fly wheel as shown in chart 207-C and revolves at engine speed regulated by the throttle, and to accurately describe it, we will now call B a revolving field.

C is now part of propeller shaft, and to accurately describe this, we will now call C an armature, see chart 207-C, and when car is running in "high speed," C follows B, because it is magnetically locked, but it will be noted that we are **driving through an air space or gap**, there being no mechanical connection at any time between the rear axle and the gas engine, only magnetism transmitting the torque of the gas engine to the rear axle.

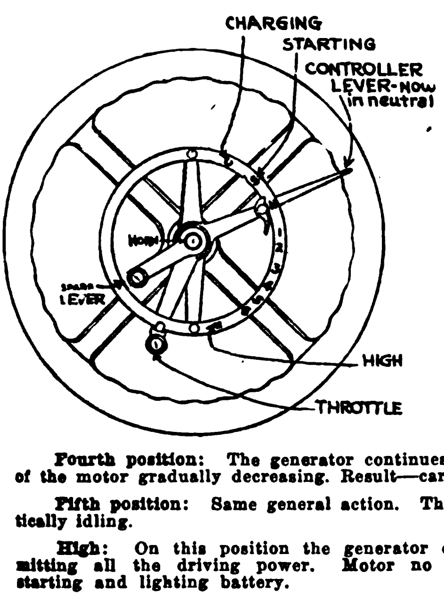
When arriving at a grade which is too steep to climb on "high," we would now stall our gas engine unless we applied a form of speed reduction.

Illustration No. 3—The conventional electric motor D, as shown in illustration 3, gives us the reductions needed in the following manner:

We now drive through what is in effect a slipping clutch, and it is apparent to us all, that if it were possible to use the power that is lost in heat through the friction of the slipping clutch in the old type gear transmission car, all the power of the engine would be transmitted to the rear wheels and there would be no use for a gear box.

The magnetic transmission gives us this result, as we now find that C is trying to keep up with B, but as B and C now have ceased to be magnetically locked, because we have changed the position of the control lever on the steering wheel, and therefore slipping, the difference in their relative speeds generates electricity which is led to D.

Armature E, being of the same form as C and on the same propeller shaft, see chart 207-C, takes the electricity generated by the slip, and acts as a power booster on the propellor shaft, giving us innumerable speed reductions, wonderful flexibility and absolute silence at all speeds.



Control Lever Positions.

Charging: Car stationary, engine running. Generator charging starting and lighting battery. Seldom necessary, as battery is automatically charged on high speed position when car is in motion.

Starting: Current from starting battery operates generator as a motor for starting engine. When engine has started, bring lever to neutral position.

Neutral: Car stationary, engine running. Clutch generator circuit is open, and motor is short circuited on a resistance. Bring lever to first position.

First position: Generator producing light clutching effect and maximum current for electric motor result—maximum difference between engine speed and car speed, and producing greatest torque or pulling power.

Second position:. Clutching effect of generator increased and current supply to motor decreased. Result—car speed increased.

Third position: Clutching effect of generator further increased and transmitting more of the driving power. The motor does corresponding less work, Result—increased car speed.

Fourth position: The generator continues to transmit more and more of the driving power—the work of the motor gradually decreasing. Result—car speed increasing.

Fifth position: Same general action. The generator carrying nearly all the load, while motor is practically idling.

High: On this position the generator clutching effect has increased to nearly locking point, transmitting all the driving power. Motor no longer assists, but operates only as generator to charge starting and lighting battery.

The gear ratio on the Owen magnetic car, 7 passenger is 4⅛ to 1 and on the 5 passenger car 3⅛ to 1.

CHART NO. 207-D—Owen-Magnetic Power Transmission System. Manufactured by the Owen Magnetic Motor Car Corporation, Wilkes Barre, Pa.

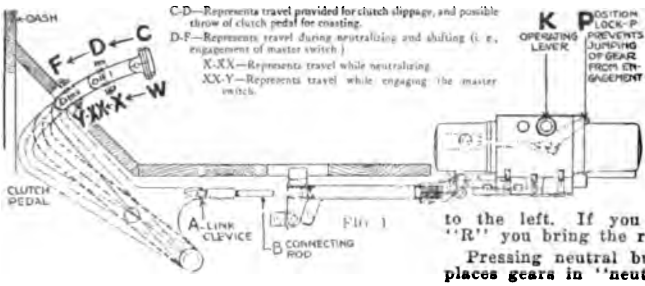


FIG. 1

Magnetic Gear Shift.

Principle—If you press the switch button 1, (see fig. 2), you close the circuit of solenoid 1, causing the shaft (A) to move to the left.

If you press button 2, you energize solenoid 2, causing the shaft (A) to move to the right.

If you press button 3, you energize solenoid 3, causing shaft (B) to move to the left. If you press button "R" energizing spool "R" you bring the reverse gear into mesh.

Pressing neutral button N and throwing out the clutch, places gears in "neutral."

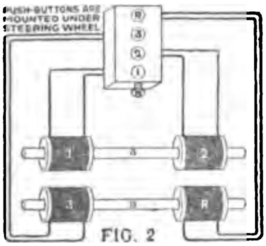

FIG. 2

Pressing a push button does not energize one of the solenoids, it merely partially closes the circuit to a certain solenoid but the circuit is not completely closed until **you throw the clutch pedal down to the floor-board.**

The clutch pedal is so arranged that you can throw out the clutch in the usual manner by **partially** depressing the pedal, but if you push the pedal to the extreme position you bring the switch (M) fig. 3, in contact for an instant and permit the electricity to flow to the particular solenoid which was selected when you pressed one of the push buttons.

The push buttons are therefore known as "selector switches" because they do not actually close the circuit but select in advance the circuit that will be energized when you push the clutch pedal to the extreme position, thereby closing switch (M).

A 12 volt battery is used—it is stated an 80 ampere hour battery will operate the gear shift from 394 to 491 times.

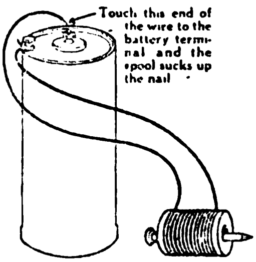

Fig. 4. Principle of a solenoid, simplified.

Gear Changes.

First speed:—To start forward in first speed, push "selector switch" button No 1 down until it catches. Then depress clutch pedal as far as it will go and first speed gears will instantly mesh. Allow clutch pedal to return gently. The clutch will engage and the car move forward in first speed.

Second speed:—Press button No. 2 until it catches and as soon as it is desired to shift the gears from first to second, depress the clutch as before to its extreme position. This brings the second speed gears into mesh. Engage the clutch.

Third speed:—Press button No. 3 until it catches. Depress the clutch to its extreme position. Allow clutch to return to engagement.

Dropping back:—In dropping back from one gear to another, the operation is the same, i. e., press the button corresponding to the gear wanted, and when it is desired to shift, simply push the clutch to the extreme limit and the gears will automatically change.

Selection:—Should button No. 2 be depressed and should it then be decided that No. 1 is wanted instead, all that is necessary is to press button No. 1. This automatically "kills" No. 2. Similarly, any button that is down is "killed" by pushing any other button. The gears may be selected in any order desired, for example—1 to 3, 2 to 1, 3 to 1, etc. It is not necessary to press the buttons in numerical order.

Pre-selection:—Speed changes may be prepared for at any time in advance of the actual shift by pressing the button corresponding to the gear into which it is next desired to shift.

When the car is stopped, the gears should always be neutralized before the driver leaves his seat, so that when the motor is again started, none of the gears will be in mesh.

Neutralizing:—To throw the gears to neutral, press the "N" button, and then depress the clutch pedal to the limit. (The neutral button has no catch and does not remain down when it is pressed. Its function is simply to throw out the other buttons in order to break their electrical connections.)

Coasting:—The clutch pedal may be thrown out far enough to free the clutch without neutralizing or shifting the gears. The shift takes place only when the pedal is thrown to the extreme position. This arrangement permits disengaging the clutch so the car can "coast," no action taking place in the gear shift. See fig. 1.

A—gear shift housing.
B-1-2-3-4—coils.
C-1-2—magnet cores.
E-E—cam shafts.
F-F—neutralizing cams.
G—ratchet pawl lever.
I—rocker arm.
J—operating shafts.
K—operating lever.
L—pawl operating master switch.
M—master switch.
N—locking shaft.
O—master switch return spring.
P—neutralizing return spring.
Z—neutralizing return spring shaft.

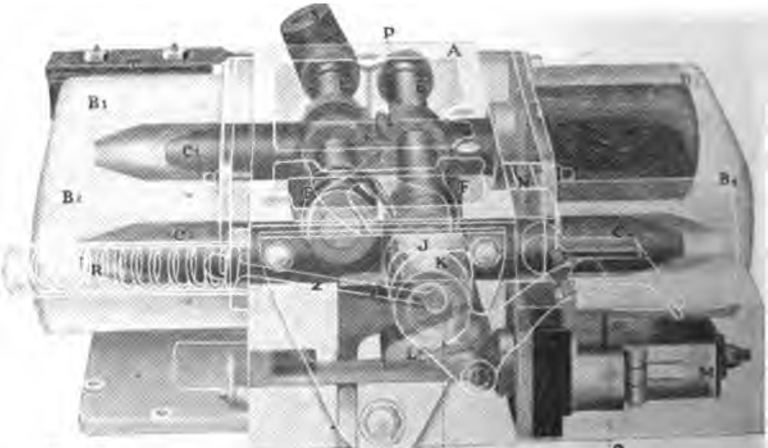

Fig. 3.

CHART NO. 207-E—The Magnetic Gear Shift. This device is used to shift the gears, taking the place of the hand shift lever and selector rods, as explained on pages 48 and 49. It is attached to the side of the transmission. The switch control is placed under the steering wheel. This system is used on the Premier Car. (Above device manufactured by Cutler Hammer Co., Milwaukee, Wis.)

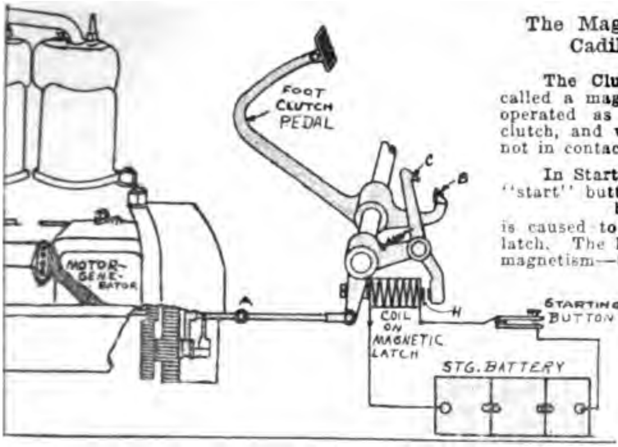

Fig. 1—On the 1914 Cadillac There is a Magnetic Latch used **in connection** with **Clutch Pedal to shift gears for starting on** the **Delco starting** system.

The Magnetic Latch Used on The 1914 Cadillac-Delco Starting System.

The **Clutch Pedal is connected with what is** called a **magnetic latch. The clutch Pedal can be** operated as **usual for throwing in and out the** clutch, and **when used for this purpose C & B are** not in contact.

In Starting **the Engine** with **starting motor, the** "start" button **is depressed** but at the same operation the current is caused to **flow around the coil on the magnetic** latch. The **lever (C) is pulled to the core (H) by** magnetism—**this action places C then, in the line of path of B and the result is, the rod (A) shifts the starting motor gears as by hand lever**

The Clutch Pedal operates free of (C) as the spring pulls (C) out of the path of B during other operations of Clutch Pedal. Thus it will be seen that the clutch pedal and starting button are used for starting per fig. 1.

The Magnetic Latch used on the 1914 Cadillac, Two Speed Rear Axle.

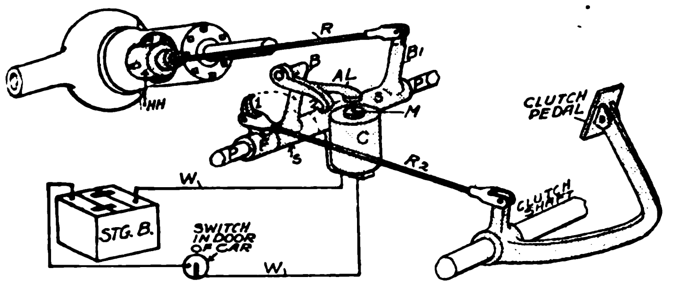

Fig. 2—There are two Magnetic Latches combined; one placed under the other, with two rods (R2) running to Clutch Pedal. One makes connection to shift L & L1 on the forward movement, and the other on the backward movement connects H & H1.

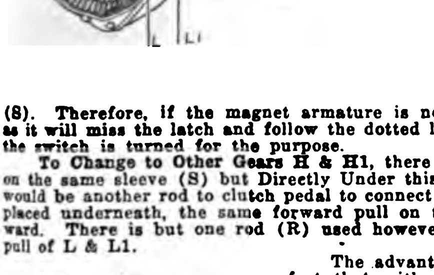
The Usual Type of Selective Transmission is Used, but instead of driving the rear axle through a single bevel gear and pinion, there are two gears and two pinions.

Gear L and Pinion L1 Mesh as the Low Direct Drive, which is 3.66 to 1 and is especially adapted for city driving, where starting, stopping and slowing down are frequent and where cautious operation is necessary.

Gear H and Pinion H1 Mesh for the High Direct Drive, which ratio is 2.5 to 1. This gear is used where speeds of 16 miles or more per hour is desired.



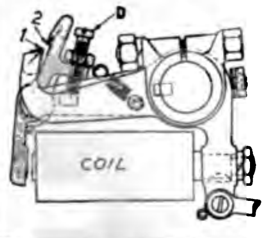
Either One Can be Connected With Drive Shaft, but in connecting one, the other is idle—for instance L & L1 work together or H & H1.

The Method For Making the Change is Done by a Magnetic Latch, on a similar principle as described above.

The Operation is as Follows: If it is desirable to have L & L1 (low gear in) then the switch on the door, is turned to the right, and down. This sends current from the storage battery through winding in coil (C). The magnet armature AL is drawn to magnet (M) causes the rod R to shift the collar in housing HH, which connects the gears L & L1 on the forward movement and H & H1 on the backward movement.

Now, When Clutch Pedal is Pressed, the Trigger 1 Catches the Latch 2 and pulls the entire apparatus which is on a sleeve (S). Therefore pressure of clutch pulls the rod (R) and shifts a coupling connection in the housing (HH). Note the trigger 1 works independent on the shaft P, as it is on a sleeve (F) free from (S). Therefore, if the magnet armature is not down, then clutch can work independent of the latch (2), as it will miss the latch and follow the dotted line. In this case clutch pedal operates this device only when the switch is turned for the purpose.

To Change to Other Gears H & H1, there is another magnetic latch (not shown in illustration) placed on the same sleeve (S) but Directly Under this one and the same operation is repeated. Therefore, there would be another rod to clutch pedal to connect to another trigger to shift coupling for H & H1. Being placed underneath, the same forward pull on the clutch pedal would "push" rod (R) back instead of forward. There is but one rod (R) used however. The motion of shift for H & H1 is just opposite to the pull of L & L1.



The advantages of the high direct drive gear ratio lie primarily in the fact that with it, any given speed of the engine produces an increase of about 42 per cent in the speed of the car. For example; at an engine speed of 700 revolutions per minute, with the low direct gear engaged, the car will travel approximately 21 miles per hour; while on the high gear it will travel approximately 30 miles per hour with no increase in engine speed.

Adjustment of Magnetic Clutch Arm.

The magnetic clutch arm (2) should be so adjusted by the adjusting screw (D) that the arm (1) will pass the arm (2) just allowing the point indicated by the arrows to clear each other when the main clutch is disengaged, and when the magnetic latch is in the disengaged position. Screwing up on the adjusting screw (D) decreases the distance between the points (1) and (2), and unscrewing the adjusting screw (D) increases the distance between these points.

CHART NO. 208—Principle of the Magnetic Latch on the 1914 Cadillac. A Delco System.

NOTE—The drawings are not drawn to scale but are exaggerated in order to simplify the principle. Although the system is out of use, it is shown in order to explain the principle.

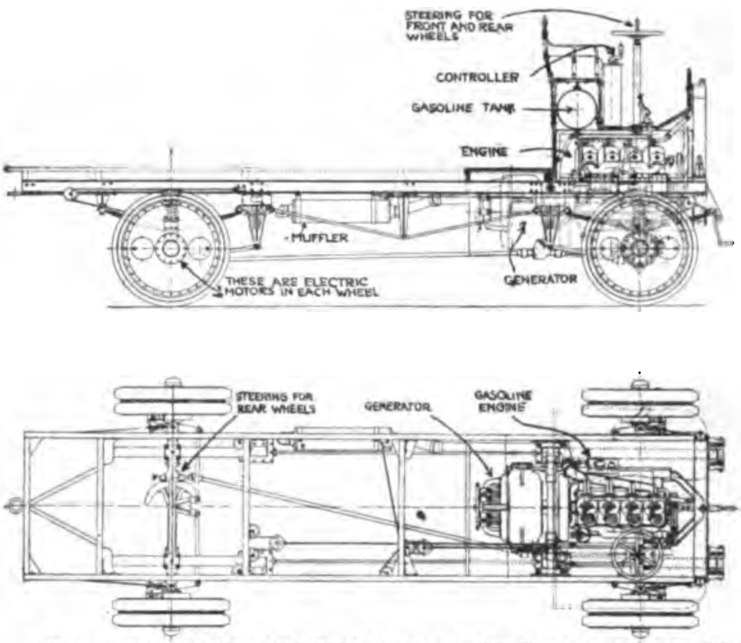


Fig. 1—A couple-gear four wheel drive and four wheel steer Gas-Electric motive power truck. Especially designed for suburban and other long distance work. Made in 3½, 4, 5 and 6 ton capacity.

Gas-Electric Truck

A very unique and satisfactory combination Gas-Electric power truck is called the Couple-Gear.

The drive system is by means of an electric motor in each wheel as shown in illustration, fig. 2. This would be termed the transmission.

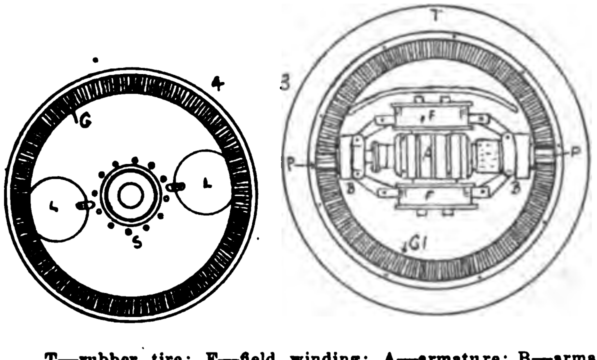
This gives a four wheel drive and four wheel steer without complications. No universal joints are used on the drive. All chains, sprockets, clutches, sliding and reverse gears are dispensed with.

"Couple-gear" transmission consists of an electric motor in each wheel, the motor armature having a pinion on either end, one pinion pulling up on one side of the wheel, the other pulling down at the opposite side, and both working at the periphery, (fig. 2). An "evener" device permits of compensating movement and divides the force "equally" between the two pinions for unequal wear or adjustments.

The gear reduction is 25 to 1 direct, and is supposed to deliver 97 per cent, of motor energy to the rim of wheel. Tires are solid 3½x36".

The power plant; is self-contained and consists of a gasoline engine connected to an electric generator. The speed of the generator, controlled by the speed of the engine governs the speed of the electric motors in the four wheels. The engine is equipped with Bosch ignition, Stromberg carburetor. 2⅛-inch five bearing crank as shown on page 80 fig. (4 S).

Generator—is designed especially for this class of work. The generator is rated 12½ K. W. at 100 volts, 680 revolutions per minute and will run completely sparkless with an ampere load 200 per cent in excess of its normal rating and with a 100 per cent rise in speed. The voltage at the maximum speed can be held down as low as 40. It is a six pole machine, with the same number of commutating poles, compound wound with a dropping characteristic, which automatically assists the engine to hold or increase speed at approximately the same rate as the increase in power is demanded for the vehicle propulsion. It is equipped with rheostat connected to fields by means of which the operator may raise or lower the gear ratio at will. Voltage can be held down to 40. Voltage drops when amperage exceeds 70. Weight 765 lbs., (see instruction No. 27, for principle of electric generator.) **Engine**—4 cylinder 5" bore x 5½" stroke.



Control.

Throttle, operated by foot lever. Ignition, fixed. Motors are operated either in series, series parallel or parallel which is governed by a controller of street railway type. Reverse lever, also on controller giving same range of speed backward as forward, and also operates an electric brake. Speed; from 7 to 15 miles per hour, 12 loaded, 16 miles without load.

Fig. 2; shows front disk and side of motor removed, giving access to the armature, field coils and bearings. It will be noted that the electric motors are mounted in the wheels which is the method of transmitting the drive power. 33 ampere 80 volt motors are used in each wheel.

T—rubber tire; F—field winding; A—armature; B—armature bearing; P—pinion (gears which drive G1); G, G1—gear in wheel; 4—steel band for tire; L—wheel inspection door; S—roller bearing.

Motor is suspended by half of motor casting, which is a heavy stub, which passes through the knuckle shaft, making the motor frame itself a component part of the axle. The armature is carried rigidly within motor frame. The wheel shell then revolves about the motor frame, on roller bearings, one of which is on the rear of frame (3) and the other in frame (4). A cover which fits over armature (A) carries this bearing for (3), but is not shown.

CHART NO. 209—A Gas-Electric Combination of Power and Four Wheel Drive and Steering.

(Couple-Gear Freight Wheel Co., Grand Rapids, Mich., Mnfgr's.)

INSTRUCTION No. 34.

OPERATING A CAR: Preparing a Car for Service. Starting the Engine. To Start the Car. Speed Changes. Running a New Car. Hill Climbing. Points to Remember. Skidding. Importance of the Clutch. Pointers on Steering. Pointers on Changing Gears. The Control Levers and Pedals. Gear-Shift Lever Movements of Leading Cars. Dash or Instrument Board of Leading Cars. How to Use the Brakes.

*How to Operate a Car.

In learning to operate an automobile, the first step is to become familiar with how to start and stop the engine and the control of the speed, which can be learned best with the engine running.

The simplest way in which this can be done is to jack up the rear wheels so that they are clear of the ground, letting the weight of the car rest on a solid box. The point is to get the driving wheels clear of the ground, and free to revolve without moving the car.

The different speeds may then be handled, and the movements of the levers and pedals gone through with, without being under the necessity of steering, the steering being the simplest and easiest part to learn. Care should be taken to block the front wheels so that the vibration of the engine cannot shake the car from its support.

Lever Systems.

There are three types of side lever systems; the type which operates the planetary transmission gears, the type which operates the old-style progressive gears and the type which operates the selective type of gear.

†**The planetary gear type** is used on the Ford car and is very simple. See Ford instruction.

The progressive gear type is now seldom used. Its principle and operation is shown on page 46.

The selective type is the type used mostly and it is with this type we shall deal with principally. This type is shown in chart 212, also page 48 and 49.

**The gear shift lever used with a selective transmission, is constructed in two types; the "gate" type and the "ball and socket" type, page 49. Also chart 212.

The emergency or hand brake lever, is usually placed along side of the gear shift lever. Sometimes these levers are placed on the side of the car, but more commonly found in the center as per chart 210. For a further description of the selective lever operation, see page 49.

Pedal Systems.

The "running" or "service" brake is a pedal operated by the right foot (see chart 210). **The clutch pedal** is a pedal operated by the left foot.

The accelerator is usually placed between the two pedals, as shown in fig. 2, page 486.

The movement of the gear shift lever for changing the gears, vary on different cars, as will be noted in chart 214. The principle or purpose however, is the same on all cars.

The spark and throttle levers are in most instances, placed on the steering wheel. On a few cars, they are placed under the wheel on the steering post. The throttle lever is usually the longest of the two. The movement of the throttle lever, whether up or down to open the throttle is easily determined by noting the movement of throttle on carburetor, the spark lever for advancing, can also be determined by noticing the direction it moves the timer or interrupter on magneto. Usually the **throttle** and **spark** lever are pushed **up** to open and to advance. See chart 213.

*If you have Dyke's Working Models of the 4 and 6 cylinder Engines, place Chart of Gear Box in connection with the model of Engine and note the relation of parts.

**See supplements. †See also Ford supplement.

Fig. 1. See that gear shift lever is in "neutral," before starting. Release hand brake, then throw clutch "out."

Fig. 2 Place gear shift lever into first or low speed position, after engine is running—but hold clutch "out" while shifting.

To Start Car.

Release the hand emergency brake: By pushing down on the button on top of lever to the left of the gear shift lever (fig. 1), and at the same time pull back slightly to release latch, then throw forward as far as possible. **Caution:—Never try to start car with the hand brake set.**

Throw out clutch: The foot pedal to the left operates the clutch. Push the pedal as far forward as possible, to disengage the clutch and stop revolving of transmission gears. (See page 41).

*Gear Changing.

First speed or low gear: With the clutch still disengaged, grasp the gear shifting lever (now in "neutral" position in fig. 2), with the left hand and pull sideways towards you. Then with a firm, sharp motion move it into first gear. (Study the numbers indicating speed changes in chart 212, and page 49). Now slowly release the pressure on the clutch pedal, letting it back gently. The car will then start ahead.

When the clutch is being engaged, the increased work thrown on the engine will cause it to slow down. Therefore, at the same time the clutch is being engaged gradually give the engine more gas, by advancing throttle lever or pushing down on the accelerator pedal. If you fail to open the throttle as the load is thrown on the engine, it is very apt to "stall." **Remember, never try to shift gears without first disengaging the clutch.** (See page 41).

Continue to run the car very slowly on first gear until you become accustomed to the sensation of driving and have mastered the operation of the steering gear. It is advisable to form a good idea of where the front wheels of the car are going to ride over the road ahead of you. As you sit in the seat and are driving along a street car track, the wheels will fit the rails—one wheel on each rail. Now sight ahead across the radiator, mud guard or hood, and set an imaginary mark there somewhere exactly in line with the rail as it passes under the machine. Riding in car tracks is bad for tires, but try the same thing on country roads when you are compelled to run in deep ruts—become familiar with where the wheels of your car are going to run and you will then be surprised to find how easy it is to judge distances—in passing other vehicles, missing stones and holes in the road, etc.

Second speed or intermediate gear: When you desire to go into second speed, push down on the clutch pedal quickly, and hold it so for a second and at the same time, with a quick, firm movement, pull the gear lever straight back, into neutral position, then push sideways, that is away from you and pull straight back (or forward which ever the case may be) into second speed, again engaging the clutch gently, and at the same time accelerating the engine when the clutch begins to take hold.

Third speed or high gear: In going from second to third speed, release the clutch as previously explained, and push the gear lever straight forward (or backward) into third speed, and again engage the clutch gently; accelerating the engine when the clutch begins to take hold.

Most of the **running** of a car is done on the **high gear**. The **starting** of a car is always done on the **low gear**.

Regulate Spark.

In cranking, the spark was fairly well retarded, but since running on retarded spark for any length of time will cause the engine to overheat, the spark should be advanced as far as possible without causing a knock. Try for yourself the change that the time of spark makes in the running of the engine. Retard the spark and with the throttle opened so that the car is moving eight or ten miles an hour, gradually raise the spark advance lever. You will note that the car would gain speed and you will be able to draw the conclusion that by using the same amount of gasoline with the spark advanced you will be able to get a greater mileage per gallon of gasoline. Consequently always use as much spark and as little gasoline as possible. The general rule is that as the engine is speeded up, the spark lever should be advanced and as it is slowed down it should be retarded.

To Reverse Car.

Never attempt to reverse car when moving forward. Bring the gear shift lever into neutral position and pull it towards you and then straight back into reverse gear. Let the clutch in very slowly and the car will move backwards.

To Stop Car and Engine—see page 489.

*Gear changing position varies—see chart 212, page 490.

CHART NO. 210—Starting Car and Changing Gears—see also pages 50 and 51.

Preparing Car for Service.

See that tires are properly inflated—see Instruction 41 "inflating tires."

Fill radiator with pure water—if freezing weather, use a "non-freezing" solution—see page 193.

Fill oil pan of engine with good grade of cylinder oil—until gauge shows full—see pages 203 and 204. The oil is poured into engine through breather pipe, see upper illustration, page 71 for location of "breather."**

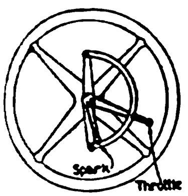
Fill grease cups—as per page 204, and see that all **wire connections** are tight—and also make sure that there is **gasoline in the tank.**

*Starting Engine.

Place gears in neutral: Be sure that the gear shifting lever stands vertical, so that no gears are engaged—see page 46.

Set hand throttle lever: The throttle is closed when the lever is down and opened when it is at the extreme top (varies; but this is general practice).

When starting, the lever should be raised about one and one-half inches from the lowest position. (This varies on different cars.) See chart 213, and page 153.



‡When starting the engine, "retard" the spark lever to its lowest position. After the engine has started, "advance" the spark lever half way, and leave it there while shifting gears.

As a general rule, the spark lever should be advanced farther for fast driving than for slow driving, and especially should it be retarded for heavy, sandy, or up-hill roads when the car is running slowly and the engine laboring. When using the low or intermediate gears on the hills or in the sand the spark lever may be advanced farther than when using the high gear.

When driving over smooth, level roads, carry the spark lever advanced three-quarters of the way up the sector for speeds between fifteen and thirty miles an hour. For speeds above thirty miles an hour, carry the spark fully advanced, that is at the extreme upper position.

Never attempt to accelerate from slow to high speeds, in high gear, without first retarding the spark to the half-way position. When attempting to pull slowly through deep sand or to go slowly up steep hills, in high gear, carry the spark not higher than the half-way position (also see chart 213).

Set carburetor air regulating handle (if one is provided): The handle usually on steering post or elsewhere (see page 159) controls the quantity of air supplied to the carburetor. When starting in cold weather, close the valve. This causes a rich mixture to be drawn in and less air. By a little experimenting you will be able to ascertain the best position for warm weather starting on your particular car.

Put switch key in place: The switch is usually located on the dash cowl. Insert the key as far as possible and give it a quarter turn. When released it will lock itself into position.

Crank the engine with starter: If a starting motor is provided, push the switch down as far as it will go with a firm unhesitating movement. Electrical connection is now made between the battery and starting motor and you can hear the engine turning over. Hold the switch down. In an instant the sound will change and the engine will then be running under its own power.

Important:—Just the moment the engine starts remove your foot from the starting switch and be sure that the lever springs back into its original position.

The time required for the operation varies from one-half second under good conditions when the engine is warm, to from five to ten seconds for cold weather starting. If the engine does not start within the mentioned time, release the starting switch, since you will know that something is out of adjustment and you are throwing an undue strain on the battery. (For full explanation of operation and care, see the starting motor instructions, referring to the type of motor system, cars are equipped with, in Instructions 25 and 26).

Regulate air to carburetor: When the air regulator handle (see page 159) is on the starting line, the air is practically shut off from the carburetor and the engine is drawing a mixture which is very rich in gasoline. A rich mixture aids in cold weather starting and the car can be driven immediately after the engine starts without waiting for things to warm up. However, a rich mixture consumes an excessive amount of fuel, is conductive of overheating and causes undue carbonization of the engine parts. Consequently, until you can get the engine to run on hot or cold air, open the air regulator to carburetor gradually to the left and leave in a position where it does the best work. Remember that air is cheaper than gasoline therefore run with as much air as possible, and slightly advance spark lever.

Close hand throttle: Do not allow the engine to race, i. e., run very fast without load. Move the throttle lever down until engine runs at fairly low speed. When leaving the car with the engine running the throttle should be entirely closed. With a little experience you will be able to ascertain for yourself the best position of the engine control parts for your particular car.

Test accelerator: Before attempting to put the car in motion, acquaint yourself

*See foot note bottom of page 489. **See also page 834. ‡This applies to starting engine by hand. Now that starting motors are used, the spark lever can be advanced slightly.

How To Change Gears.

Changing from Low Speed to Second Speed.

Fig. 2—Assuming the car started and running on first speed, before making the change to second speed fig. 2, it will be necessary to have the car traveling at such a rate—that the drop in speed during the length of time it takes to bring the gearshift lever from the first speed position, through the neutral gate and into the second—will not result in the car traveling so slowly that there will be difficulty in the engine picking up the load. It will not be necessary to attain a speed of more than 7 miles an hour to make this change on level ground. When a speed approximating this has been attained, make the change by a smooth but **quick** pull on the lever. You should practice the movement to such an extent, that the transverse movement in going through the neutral gate movement, will be made so quickly that it will hardly be apparent and will not interrupt—to a perceptible degree—the smooth movement of the gear-shift. In making the change to a higher speed, it is necessary that the throttle be opened as soon as the gears are meshed. The spark is also at once advanced slightly.

Changing from Low Speed to Second Speed —on a grade.

When the car is facing upwards, it is a little more difficult to be able to judge when the speed is sufficiently great to justify a change from first to second speed. The hill may be of such slope that it is an easy matter for the car to take it on high in ordinary running, but is still steep enough that the pause in the gearshifting act, is sufficient to cause the speed to drop considerably. In a case of this kind the driver should be able to judge just at what speed he should throw out his clutch and make the change. The steeper the hill the greater will be the speed required before the change can be safely made.

Fig. 3—In going from second to high speed the same directions apply, except that the complication of passing through the neutral gate is not present, and therefore the change is simplified to a slight extent.

In Changing from a Higher to a Lower Speed —high to first.

Fig. 9—In dropping from a higher to a lower speed a different set of circumstances will arise and a different method will have to be pursued.

When traveling through traffic it is sometimes desirable to change to a lower gear on level ground without slowing down the car. To attempt this by de-clutching and putting the lever directly into the lower speed notch—in the same way that this is done while ascending a hill—would be to invite a very noisy clash of the gears.

Instead: the change is made in three progressive steps, as shown in fig. 6 and fig. 1, and the speed of the car is not reduced to any appreciable degree.

The first movement shown at A in the illustration below is to disengage the clutch and carry lever forward from high to neutral. This leaves the car coasting with the engine running.

The clutch is now let in and the levers are in the position shown at B. Now this is the part where the skill is required and where practice is necessary.

—see further instructions under fig. 11 and illustrations below.

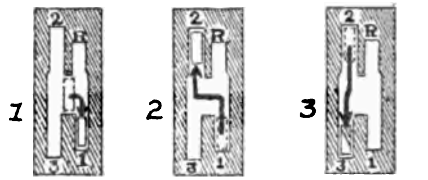
The engine is speeded up until it is turning over at the same rate of speed as it would be were the low speed engaged. It will take a little practice to accustom the ear to judge by the sound of the engine whether it is turning over at the correct speed or not.

After the engine is speeded up to the proper degree, the clutch pedal is depressed, and the change gear lever brought into low speed as at (C). **The same method will apply in going from second to first.**

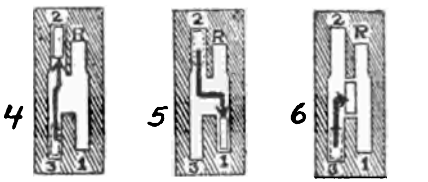
Trouble in dropping to lower speed on a hill can be averted, if the critical moment at which to make the change is learned. **If the driver waits too long** he may "kill the engine" and sometimes place himself in a very serious position.

If he tries to make the change too soon he will clash gears.

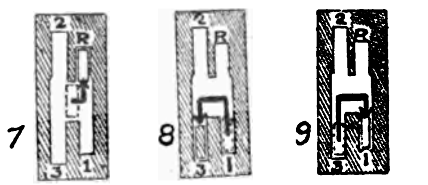
By changing at the critical moment however an easy, quick change can be made.



Neutral to Low Low to Second Second to High



High to Second Second to Low High to Neutral



Neutral to Reverse Low to High. High to Low

Above illustrations explain the movement of shift lever to obtain different changes of gear. For instance, Fig. 1 shows the change from neutral position to first or low speed; Fig. 2, shows change from 1st to 2nd, and Fig. 3. shows change from 2nd to 3rd.

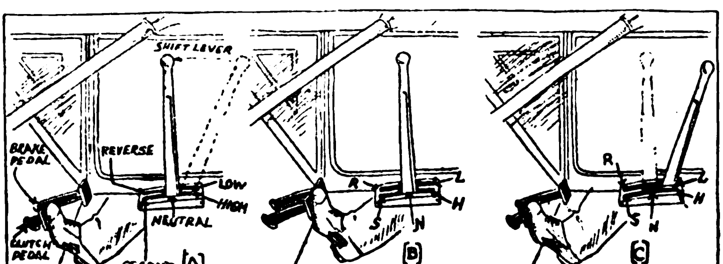


Fig. 11—Changing from "high" to "low."

A—clutch out and lever brought to neutral; B—clutch engaged with gears in neutral and engine speed regulated to correspond to speed of car on low gear; C—clutch held out with foot—gear shift lever is then moved back to low gear position and gear change is completed.

CHART NO. 211—Pointers on Changing Gears; movement of lever.

The above gear shift was used on early model Overland cars. The later Overland, Willys and Willys-Knight cars and in fact a majority of the three speed cars use gear shift as per fig. 1, page 490.

with the operation of the foot throttle or accelerator. The pedal is usually located between the two large pedals on the foot boards and by pressing down, the engine may be speeded up, but when released it will spring back, slowing down the engine to the speed allowed by the position of the hand throttle on the dash. Note how quickly the engine responds to the pressure of the foot. The success you will have in making gear changes, will largely depend upon the sensitiveness of your foot pressure. (See fig. 4, page 154, for explanation of an accelerator—see also chart 213).

Starting car and changing gears—see chart 210 and 211.

†To Stop Car.

Remove foot from accelerator to slow down engine and disengage clutch by pushing left pedal forward. Then apply the brake by pushing forward on the right pedal. When the clutch is disengaged the engine power ceases to drive the rear wheels, but the car will continue to coast, due to its momentum. The foot brake is used to overcome this momentum and should never be applied against the power of the engine, i. e., when the clutch is engaged. Do not slam down on the brake pedal and lock the rear wheels, for this not only shows lack of good judgment but is extremely hard on tires and may cause disastrous skidding. Anticipate the stop to be made far enough in advance, to enable you to bring the car to a gradual stop.

Before letting back on the clutch pedal move gear shift lever into neutral position. If you fail to do this the car will start ahead when the foot is removed from pedal and the engine is very apt to stop running, i. e., "kill the engine."

Emergency stop: Push both pedals forward and at the same time pull back as hard as possible on the hand or emergency brake lever. Do not get excited and pull back the gear shift lever. Remember, the brake is the longer lever furthest from you. (See fig. 1, chart 210).

If the road surface is wet and slippery a greater braking effect may be had by pushing in on the foot brake pedal intermittently, i. e., hold the brake pedal down for an instant only, then release and apply again. Keep doing this until the car is brought to a stop. If the brake is constantly applied the rear wheels will be locked and traction will be lost.

To Stop the Engine.

Turn switch key to "off" position. At the same time press the accelerator pedal, thus opening the throttle after the spark has been cut off and allowing the engine to draw in a rich mixture while coming to a stop. The gas drawn in will remain unexploded in the cylinders and greatly facilitate future starting. See page 321.

Be sure the clutch is thrown "out" or gear shift lever in "neutral" position when stopping engine.

To stop the engine in cold weather so that it can be restarted easily, shut off air to carburetor by moving the air regulating handle in a right-handed direction to starting position. If this in itself does not stop it, then push in the switch key to short circuit the magneto.

When leaving the car, always remove the key from the switch, so the engine cannot be started without your knowledge.

**Running a New Car.

In setting up and starting any new piece of complicated machinery, you would expect to watch it pretty closely and go a little easy until its various bearings, parts, etc., had become thoroughly "worked in." An automobile is no exception to the rule. While every bolt and nut in the automobile is drawn tight, and secured with either cotter pins or lock washers when the car leaves the factory, nevertheless it is advisable to go over a few of the more important points and make sure that everything is in perfect shape. (see pages 203 and 651, "running in" a new engine.)

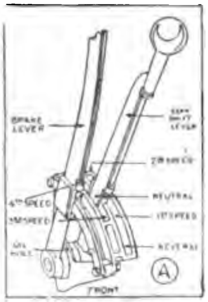
The folowing points should receive your special attention, during the time the car is being driven the first few hundred miles: Between the upper crank case and the oil pan, there is usually a gasket, see page 62 and 64. During the first few days of service the gasket may become slightly compressed, thus loosening the crank case to oil pan bolts, consequently go over the nuts on the bottom of the oil pan with a wrench and tighten them up. Drive a few days and try them again. Continue to do this until the gasket has become fully compressed and the parts have settled into permanent working position. If you will take this precaution the joint will be absolutely tight and you will never have any trouble, such as, loss of oil or water and dirt being washed into the oil pan and then circulated with the oil through the bearings, causing excessive wear and cutting.

At first, occasionally go over all of the **bolts** (illustration E, page 64), **that hold the engine to the frame,** and see that they are kept tight. If you find them perfectly tight after inspecting them two or three times, you

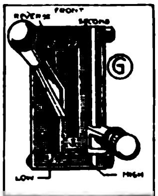
***Starting engine by opening switch** is unusual but it is obvious that the idea of flooding the carburetor is to obtain a temporary enriched mixture, but the value of the flooding is lost if it be done when the cylinder and induction pipe are full of mixture, any gasoline vapor left in this overnight having long since evaporated.

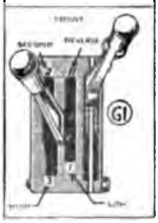
If the engine be turned over a few times with the switch off, the air is expelled, and a thin mixture of air and gasoline inhaled in its place. Flooding then gives a temporarily rich mixture in the cylinders and the engine will start at the first trial with switch on. Also see page 153.

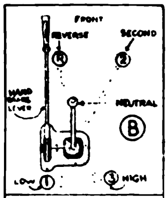
†See also page 495. **See pages 203 and 651.

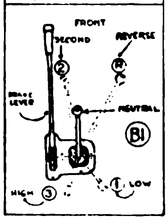


A four speed gate type gear shift; Pierce-Arrow. See page 500, fig. 22, for Locomobile.









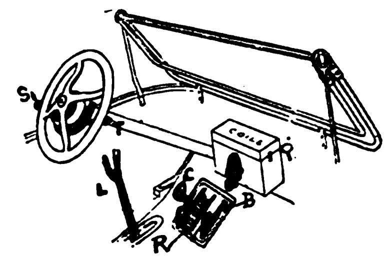


Fig. 9—The Ford—L, is the high speed and brake lever; C—clutch pedal; R—reverse; B—brake pedal; S—spark lever; T—throttle lever.

Gear Shift Movements.

The three gear shift principles in general use are shown in the above illustrations. The one other type, fig. 9, is the Ford, which is also explained under the Ford instruction.

Three speed gate type: The gate selector is plainly shown in G and G1. The gear shift lever is shown in neutral position. By moving this lever to the side, then forward or backwards the different gear shifts are obtained. Note in G, the first or low speed is obtained by moving the lever back, on the left side, whereas in G1, first speed is obtained by moving lever backwards to the right. G is the S. A. E. Standard fig. 1, below, and is used most.

The ball and socket type gear shift: Is shown in B and B1. This principle is also explained on page 49. The lever in this principle shifts the gears in precisely the same manner as in the gate type selector, but instead of a gate, the ball and socket is used to obtain the various movements.

When in center position, lever is in "neutral." Note in B, to obtain first or low speed, lever is shifted backwards, to the left, whereas in B1, it is shifted backwards to the right. The ball and socket type, is the one most cars are equipped with at the present time and B, corresponds with the S. A. E. Standard fig. 1 below and is used most.

Four speed gate type selector: The Pierce-Arrow gear shift is illustrated in A. This principle corresponds with S. A. E. Standard, fig. 2 below, see also page 500, fig. 22 for Locomobile four speed gear shift.

**S. A. E. Standard Gear Shift Movements.

The gear shifts as recommended by the Society of Automotive Engineers are illustrated as follows:

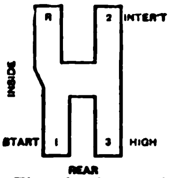

Fig. 1—3 speed.

Fig. 1 — Three speed movement; R—is reverse; 2—intermediate or second speed; 1 — low or first speed; 3—third or high speed. Note reverse and second speed are forward movements.

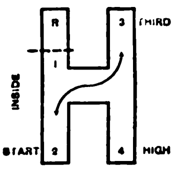

Fig. 2—4 speed.

Fig. 2—Four speed movement: This corresponds with Pierce-Arrow above (A) and Loco, fig. 22, page 500. Note the reverse is a further movement in slot with 1st speed movement.

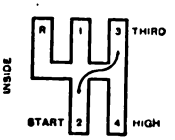

Fig. 3—4 speed.

Note difference is in reverse.

Fig. 3—Four speed; same as fig. 2, except the reverse (R) is in a separate slot; to the side of the 1st speed (1).

Four-speed transmissions for motor trucks shall have gear-shifts so arranged that the lever-handle positions for forward speeds are as shown in figs. 2 and 3. The high-gear (or 4th speed) position corresponds with that for three-speed transmissions (3—fig. 1), and low-gear (or 1st speed) position corresponds with reverse (R) for the three-speed transmission.

The location of reverse position is left optional, it may be as arranged in figs. 2 or 3, or could be in a separate slot as per fig. 3, but in rear instead of front —which is the method as used on the Garford truck and many others, but there must be protection by a latch or equivalent against accidental engagement of reverse.

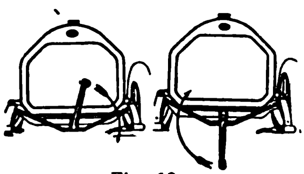

Fig. 12.

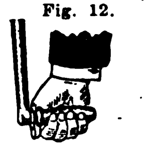

FIG. 13 How to Hold the Crank. Proper method to grasp handle of starting crank. If started by hand, otherwise see electric starting instruction

***How To Use A Starting Crank.**

Fig. 12 — Always pull up on a starting crank — never push down. With the crank hanging straight down, push it in as far as possible and turn in a right-handed or clockwise direction until it catches. Now pull crank over against the compression as quickly as possible by giving it a quarter or half-turn in the right hand direction. The engine should start. If it does not start after doing this three or four times, do not tire yourself out by continually cranking. Something is in need of attention. Analyze the cause of trouble in the manner outlined in "digest of troubles" Instruction 43, and remedy accordingly.

CHART NO. 212—Gear Shift Movements Explaining the Difference between the Gate and Ball and Socket Type—see also pages 49, 496, 497 and 543 to 546. **S. A. E. Standard Gear Shift Movements.**

*The starting crank is now seldom used but occasionally it is necessary, therefore instructions are given as a matter of information. **The gear shift of the A and B Army Truck is as per fig. 3 and 1.

need never fear that they will loosen up.

It is advisable to put a wrench to all nuts on different parts of the car and make sure that they are perfectly tight after it has been driven a hundred miles or so. When they have once been screwed up as tightly as possible and the car has been thoroughly "run in," there will not be so much danger of loosening up and causing damage.

Spring clips fig. 8 (upper illustration), **page 26, will loosen** if the nuts on the clips are not tightened ocasionally. It is **very** important to tighten these nuts often. **Fender bolts** also demand attention. **The universal joints** should be kept well supplied with grease, see bottom of page 43.

Lubrication of a new car. It is needless to remark that lubrication is one of the most important things to look after on a new car. All parts should be thoroughly lubricated and greased as directions provide on page 196, and follow along the lines as there suggested. In the absence of directions from the maker study the lubrication subject carefully. Remember one thing—cheap oil will cost ten times more—maybe a hundred times more in the long run, in the way of repairs. The best oil is none too good.

Draining oil from engine: When the engine is assembled every part is cleaned as thoroughly as possible but in the early stages of service, small metallic particles may be shaken or worn off the engine parts, falling into the oil reservoir. Consequently after the car has been driven about two hundred miles drain out all of the old oil as per directions. See also page 201.

After having drained the crank case and transmission case, rinse out with kerosene, replace screw plug in the oil reservoir and pour the kerosene through the breather pipe, if so equipped using a gallon or more. With switch plug **removed,** push in on the starter pedal so that the engine turns over rapidly for ten or fifteen seconds. By running the engine with the starter for a very short interval the kerosene will be forced through the entire oiling system, flushing it out and then running out the lower drain plug hole, which should be left open. Drain out the kerosene very thoroughly, and then replace all plugs and refill the oil reservoir. The transmission will be refilled by the fly wheel as soon as the engine starts (if it is a unit type). The oil will then lower and no doubt more oil will be necessary. If you wish to derive the best results from the oiling system, this operation should be repeated after the car has been driven another five hundred miles or thereabouts. After this the oiling system needs to be rinsed out only once every thousand miles and it will require no other attention since now the oil is bound to be clean and it is positively circulated to every moving part with little chance of failure.

Hill Climbing.

Until you have become thoroughly familiar with the operation of the car, and have mastered the things necessary to make a good driver, do not attempt to climb every hill you see" on high," because your neighbor possibly has said that his car would do it. There can be nothing more detrimental to the engine and driving parts than to try climbing every thing on "high." The first and second speed gears are placed in the car for a purpose, and if the hill that you are approaching is at all steep, shift into "**second**" a little before you are really on the hill. Do not try to go into "**second,**" however, at any time unless the speed of your car has been reduced to the pace at which the second speed would carry you if it had already been changed. Many accidents, and serious ones, have resulted from a driver attempting to rush a hill "on high," getting half way up and having the speed of the engine so reduced that when he came to shift into low it was too late; the engine would not accelerate sufficiently to carry the car up on low, and possibly the brakes were not working just as they should, the result being that the car would back down the hill faster and faster, until it finally landed in the ditch. Backing down hill with brakes is a task for a skillful and experienced driver and even he cannot guarantee a good job. It is a most confusing situation and requires instant good judgment.

The secret of successful hill climbing is to at all times keep your engine running a little faster than its work requires it to run, i. e., keep it "ahead" of its work so that it is ready for extra duty without stalling at the critical moment. The foregoing does not mean that it is impossible to climb many hills "on high," but it is best not to try until you are sure of yourself and of your ability to get into **second,** or even **first** if necessary, halfway up the hill, and also to determine from the sound of the engine whether it is "working hard." If you must go into a lower gear on a hill, shift with a quick, firm movement and take care not to let the momentum of your car be reduced any more than is absolutely necessary. Every second that you have the clutch disengaged on a hill for gear shifting, counts, as the car slows down at a very surprising rate.

If in climbing a hill on "third," the engine has been stalled before reaching the top, it may require considerable skill to start from your standing position on the incline. Immediately upon finding yourself in such a predicament, apply the emergency brake with all your strength and **be sure** that the brake ratchet catches, then throw the gear shifting lever into neutral. After starting the engine again, push out the clutch (leave the hand brake still on), push the gear lever into **first** speed and slightly race the engine (the only time it is permissible, excepting when in a mud hole or the like)—take hold of the hand brake and keep the engine speeded until the brake has been entirely released, the clutch entirely engaged, and a safe start has once more been made up the hill. Experience is the best possible teacher where there is a considerable amount of hill work to do.

Learn to drive your car by ear. Learn what the different little sounds that vary under different running conditions mean. If the speed of your engine has been so reduced by running through a heavy stretch of sand, that you can almost count the explosions and at each impulse you feel the whole car jar, you can rest assured it is high time you went into a lower gear and let your engine do the hard work a little more advantageously. No matter what the power of your car; hills, sand and hard work have to be met very much the same way. **Remember**, keep the engine ahead of its work and at the same time do not "race" it unnecessarily.

***In descending a long hill it is possible, even advisable to use the engine as a brake,** and if the hill is not too steep, the descent can be made without resorting to the use of the rear wheel brakes. To accomplish this, shift into first or low gear, close the throttle and leaving the gears and clutch engaged, open the ignition switch to stop the engine from firing. As the car coasts the rear wheels will be forced to turn the engine over against compresson in the cylinders, hence the braking effect. By opening the throttle the resistance is still further increased. The maximum of resistance and the best control on a dangerously steep hill may be obtained by shifting into first, switching off of the ignition, and applying the brakes at intervals. Just before reaching the bottom of the hill, with the car still moving at a fair pace, close the ignition switch and the engine will start firing again.

On a long descent, when you find it necessary to use the brakes, apply the hand and foot brakes alternately, to avoid burning out the brake linings.

Points to Remember in Operating a Car.

Starting by hand: This sounds ancient, but no doubt there are many of the older models of cars with hand starters still in use, therefore as a matter of "information" we will devote a few lines to the subject.

Grasp the starting handle as shown in fig. 13, chart 212; that is with the thumb on the same side of the handle as the palm. Never bear down on the crank. You may do it safely many times, but you incur the risk of a kickback; so don't do it.

Cranking is not an art, but simply a "knack." You will realize this better after you have seen some one physically much weaker than yourself start an engine that you seemed totally unable to throw over by main force. Get the fly wheel to rocking to and fro, until with a last, powerful acceleration the piston is carried over its compression by the momentum of the fly wheel as well as by the pull of your arm. A new engine always turns over somewhat stiffly, because all bearings are closely fitted, to insure long life. After a little while, it will "loosen up."

If it does not start on the first upward pull, because the cylinder walls are still cool, or because the first and incomplete suction stroke has not brought sufficient gas from the carburetor into the cylinders, repeat the operation once or twice and the engine will start at a lively pace; otherwise see "Digest of Troubles."

Control of the speed of engine: (See page 67 and chart 213.) The throttle lever connects to the throttle on the carburetor. By opening the throttle lever, more gas is permitted to enter the cylinder and consequently more speed.

To increase the speed of an engine, the usual procedure is to open throttle and as the throttle is advanced, gradually advance the spark.

To decrease speed, retard spark and throttle. When the spark lever is moved, on the steering wheel, it in turn moves the timing device, or commutator, or contact breaker; either advancing it so that it will make contact **early**, or retarding it so that it will make contact **late**. It is possible to often times govern the speed of an automobile when a small amount of gas is being used, by advancing or retarding the spark. In "advancing," the speed is increased and in "retarding," the speed is decreased.

The Accelerator.

There is another pedal which also performs some of the functions which so far have been taken care of by the hand throttle lever, and this other pedal is the so-called "foot throttle or accelerator." It is located in the neighborhood of the right foot. Pressing it down opens the throttle and a spring tends to close it as soon as the pressure against it is discontinued, as illustrated on page 154, and fig. 23, page 497.

The hand throttle lever and the accelerator are inter-connected. See fig. 4, page 154. Advancing or retarding the hand throttle lever will move the accelerator down or up. But pressing the accelerator will not actuate the hand throttle lever. It is therefore possible to set the hand throttle lever for any desired minimum speed and to this minimum speed the foot throttle, or accelerator will conform. For instance, should you first set the hand throttle so that the car would proceed at the rate of, say, twenty miles an hour, and then use only the accelerator, the latter will not close the throttle below the mark for which the hand throttle is set.

In operating the car it is possible to use either. Using the accelerator gives greater freedom to the operator's hands. The hand throttle lever is used in starting, and in touring as an occasional relief, to rest the foot at times when the car is run considerable distances without material changes in its speed (see chart 213).

*In other words the car will run the engine, and owing to the fact that you are in low the gear ratio is such that the car has the long end of the lever, to get an idea of what this means; jack up the hind end of your car sometime and put it in low; then try to turn the rear wheels.

*Importance of the Clutch.

The clutch of an automobile is a device by means of which the power of the engine and the driving mechanism may be connected or disconnected at the will of the driver. This particular part is probably used more than any other part of the car, and a careful study of its purpose and principle is advised. Though the device is simple and its use plain at first glance, the clutch, nevertheless, lends itself to a number of skillful uses in the hands of the experienced driver. **Remember to always "throw out" clutch before changing gears,** see chart 210, and pages 37 to 44.

When the clutch is "let in," or engaged, this should at all times be done smoothly and so gradually that the motion of the engine shaft is transmitted to the drive shaft without jarring.

A suddenly let-in clutch will do one of two things; either rack the mechanism of the entire car, or stall the engine. With a little practice the left foot may be schooled to let the clutch in quickly, yet gently and smoothly.

When you meet a stretch of road covered with sharp, broken stones, it is an excellent plan to speed your car a little before you reach the stones and then disengage your clutch, permitting your car to coast over the bad spot. By shutting off the driving power you protect your tires against a very destructive action, termed the "traction" which otherwise would be set up between the sharp stones and the tires.

When reversing, remember to bring the rear wheels to a dead stop before letting the clutch in. Complete familiarity with the motions of going from one speed to another and back again should also be acquired before attempting to run on the open road, see pages 51 and 488.

When the control of the engine and change speed gear is well understood, the first run on the road may be made, but first study the rules of the road (page 502).

Instructions on Steering a Car.

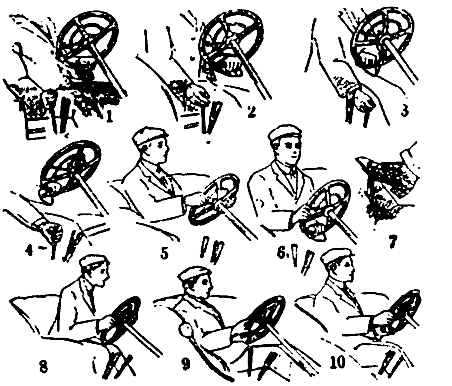

Fig. 4.—Correct and incorrect positions in driving: 1—Fierce grip, a bad method; 2—Correct hold for forward movement; 3—Finish of forward movement; 4—Alternative grip suitable for many gears; 5—Awkward hold of wheel; 6—Proper and comfortable hold; 7—Wrong foot position; 8—Nervous, uncomfortable position; 9—Careless, lounging position; 10—Correct "seat." (Popular Mechanics.)

The positions to assume in steering or driving a car are shown in fig. 4. A very slight movement of the steering wheel or lever is sufficient to turn the car, and too sudden a turn may cause an upset.

Select a straight road, as wide as possible, and with the engine running slowly, throw in the low speed. The car will move forward slowly, and it will then be necessary to steer. The first inclination will be to grip the wheel as tightly as possible, but after a little running a light grip will be found sufficient. At this stage it is necessary to learn **self-control** first and not to get rattled.

If the car begins to run off the road, or into an obstruction, throw out the clutch and apply the foot brake so that it comes to a standstill. When the excitement has died down, try again, and it will not be long before steering comes easily.

There is no time lost between the turning of the steering wheel and the turning of the car; when taking a corner do not move the wheel until the car is at the point where turning is necessary.

†Pointers on Changing Gears.

When taking your position in the car, place the speed gear lever in the "neutral" position, release the brakes, "throw out" the clutch. Practice pressing the clutch pedal and releasing it, until the feel of it is understood, (see fig. 1, chart 210).

The clutch pedal should be depressed sharply, and released slowly, which throws out the clutch quickly, and throws it in slowly. Do this a number of times, until it becomes natural and well understood.

Speed up the engine slightly, throw the clutch out, and move the control lever forward to the notch that indicates the slow or first speed.

Always let the clutch in slowly. The clutch must be permitted to take hold gradually—let it slip a little at first, to pick up more and more of the load, so that finally it turns the wheels steadily. When the clutch has taken firm hold, throw it out, and move the control lever back to the neutral position.

These motions should be gone through a number of times, until familiarity with it makes the gears and clutch go in and out of engagement smoothly.

Get the wheels going on low speed, and then move the control lever to the inter-

†By referring back to instruction No. 6, on pages 48 and 51, additional pointers and information can be obtained; see also page 488. See also, foot note page 662.

***Learn to drive by throttling the engine instead of constantly throwing clutch out.** The average driver uses the clutch about twice as much as he should.

mediate or second speed. Always throw clutch out with foot pedal before changing speeds.

When the change from low to second speed is well understood, and can be performed smoothly, move from second to high, increasing the speed of the engine sufficiently, and being sure to first throw out the clutch. *If the gears do not go into mesh easily, but grind and growl, try it over again, coming back to low speed first. Never try to force them, but make the change quickly.

When running fast, never suddenly make a change from high to a lower speed. This change must be made when car has slowed down, and it is evident that the engine will not pull the grade on the high speed. The gears, however, can be changed from first to second and second to high when engine is running moderately fast.

The usual plan is to start the car off on low speed, then after car is in motion, change to second, and when car is well under way, then to high speed.

The low speed and second speed are used principally for starting a car off and for climbing hills most of the running being on high speed.

When running on low and second speed, the engine speed should be as low as possible, to keep it from overheating.

A car is usually run on high speed, because then the engine is running slowly in relation to the speed of the car.

The best driver gets the greatest distance with the fewest revolutions of the engine, which means less wear, and less fuel and oil.

The lower speeds are principally necessary for hill climbing, for which the engine must have more pull or better leverage on the wheels to take the car up.

As the car ascends the hill, the engine will begin to slow down as it feels the load. Retard the spark gradually, giving more gas to keep engine working smoothly, but when it slows down and shows signs of distress, it is time to change to second speed.

Coasting.

Coasting mountain roads. Whenever you approach a long and steep grade, it is best to shut the throttle, switch off the ignition, put your gear speed lever into first speed and allow the car to run the engine.† This is better than using the brakes. As it gives you absolute control of the car at all times.

If the grade is long and steep, use the foot and emergency brakes alternately. This equalizes the wear on them.

While the speed of the car in going down hill may be kept under control by the brakes; the engine can also be used as a brake. The engine is then being driven by the forward movement of the car. The effect is to convert it into an air compressor, and the resistance it will present will keep the car in check on all but the steepest hills. This will also have a cooling effect on the engine and save the brakes, which on a long hill are liable to be burned and ruined. The switch should be turned on again, however, before the bottom of the hill is reached so that the engine will start to run again under its own power.

How to use the Brakes.

When the brakes are suddenly applied with full force to the wheels of a car speeding along at the rate of say, thirty miles an hour, the braking action will be so powerful as to stop immediately the rotation of the driving wheels—but the car will not come to an immediate standstill; its momentum will send it forward and the locked rear wheels will slide over the ground with most destructive effect on the tires.

When you consider that in railroad practice the so-called "flat wheel" is produced by too sudden braking, you will be able to appreciate the effect which a similar practice must have on the soft rubber tires of an automobile.

Bear in mind, therefore, that the best method of using the brakes is that which applies pressure on them so gradually that the forward movement of the car and the rotation of the wheels come to a stop **together.** See pages 492, 28 and 29.

Nothing is more severe on a car than the **spectacular** stopping often indulged in, by ignorant drivers, in an effort to "show off"

The careful driver shuts his power off before he reaches the stopping point and permits the car to carry him along on its momentum, bringing it with a gradual application of the brakes, to a halt at the exact spot.

Although the foot or service brake may be used to slow the car down while the clutch is in engagement, it is poor practice to do so and would burn the brake lining.

Whenever it becomes necessary to slow down, release the clutch first; that alone will have an immediate slowing-down effect on the movement of the car, because it disconnects the power. If additional checking is needed, apply the foot-brake or, for a quick stop, the foot and emergency brakes together. To make it plain the **clutch pedal goes down first, the brake pedal next.**

If a full stop is not desired, merely a temporary slackening of the speed, release the brake pedal first, then let clutch pedal

*See charts 211 and 212 and study the change of gears and operation of the selector lever.

†Note: This plan is used only in an emergency. The pistons have a tendency to draw gasoline into cylinders which works down into crank case and thins the lubricating oil.

come up. If you did the reverse, the engine would be compelled to pull against the brake, with consequent rapid wearing down of the brake lining. (See also "brake adjustments," in the repair subject.)

No motorist is qualified to give his car the best care until he has mastered the control of the gears and of the brakes.

Slipping brakes are usually caused by oil working out the rear axle onto brake lining.

If the Brakes Fail.

If the engine stops while descending a hill, the brakes should be thrown on at once to keep the car under control. If poor adjustment of the brakes renders them insufficient for this, then place gears in low speed, this will tend to check the car. It is then a matter of steering the car to best advantage. **If ascending a hill and engine stops and brakes fail,** try putting gears in reverse. This will then turn the engine in right direction and ought to start it. It may be possible to steer it—owing to its extremely slow speed—off the road into a bank or other obstruction that will stop the car without much damage to it or its occupants.

Situations such as this require a cool head and steady hand, and the more experience in operating the driver has, the greater are the chances for handling it in the right way.

*Stopping a Car.

Stopping a car on an up grade and starting again requires skill, for the brakes must be withdrawn and the clutch let in at the same instant with one movement.

Until this skill comes through experience, the best thing to do when this is necessary is to block the wheels with stones or pieces of wood.

The beginners' idea of stopping is to throw off the power and put on the brakes. While this will of course, produce the desired effect, it is not correct, for it would rack the car and damage the tires. The car is heavy, and when moving tends to keep on moving, so that its stops must be gradual.

To stop, first retard the spark and throttle, to keep the engine from racing when relieved of the load. Make up your mind just where the car is to stop, and throw out the clutch a sufficient distance ahead, for the car to come to a stand of its own accord.

Brakes should be applied suddenly only when it is absolutely necessary, for they are powerful enough to lock the wheels and make the car slide. Sliding grinds the tires and means their quick ruin. The flashy driver, who brings his car to a sudden stop, is piling up a big repair bill.

When the brakes are to be applied, pressure should be brought on them gently at first, being increased gradually so that the car slows down gently.

It is easy to learn to estimate the distance at which a car will come to a stop when the clutch is thrown out, so that the coasting of the car may be utilized in slowing and stopping it.

When stopping, get into the habit of retarding the spark and throttling the mixture. By opening throttle just before shutting down the engine (with clutch out) starting the next time will be easier, as you are filling cylinders with gas.

If only a short stop is to be made, the engine may be kept running at its slowest speed, called "idling," but if the stop is to be for some time, cut off the ignition.

For a quick emergency stop, bear down on your foot clutch and foot brake pedal, at the same time pull back on the emergency brake, chart 210, fig. 1. The foot brake pedal (called the running brake) will do for all ordinary purposes and the emergency is used only when a quick stop is desired.

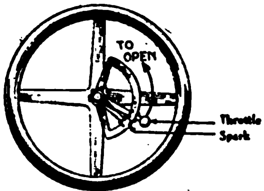
**When the Car Skids.

Although the driver feels helpless at first, a little experience will soon give him confidence. Most skids can be corrected by the manipulation of the steering and brakes. An expert driver can keep his car straight under almost any conditions, but it is impossible to explain just how he does it. Usually the rear end skids first, and in the right hand direction, this being caused by the crown of the road. Under such conditions, the skidding action will be aggravated if the brakes are applied, and the car may be ditched or continue to skid until it hits the curb.

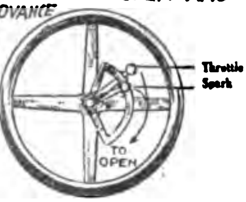
The correct action in an emergency of this kind is let up on the accelerator pedal to shut off the power; but not entirely so, or it will have the same effect as putting on the brake. If the car seems to right itself, the power may be applied gradually and it will be advisable to steer for the center of the road again. However, if the car continues to skid sideways, steer for the center of the road, applying the power gently. This will aggravate the skid for the moment but will leave you with the front wheels in the center of the road and the car pointing at an angle. By so doing, you can mount to the crown of the road again and the momentum of the car will take the rear wheels out of the ditch on the right hand side. It is customary to advise turning the front wheels in the direction that the car is skidding, in order to correct the action, but this can hardly be said to be true in all cases, it holds good where there is unlimited side room, but usually the car hits the curb or is in the ditch, before you can straighten it out with the steering wheel.

*See also page 489. **See page 551.

Spark and Throttle Lever Movements.



NO. 1- UP - TO OPEN AND ADVANCE



NO. 2 - DOWN - TO OPEN AND ADVANCE

The spark and throttle lever used on most cars, move up to open throttle and advance the time of spark—as in fig. 1.

Some of the cars using the up movement are: Jeffery, Overland, Studebaker, Saxon, Paige, Regal, National, Pullman, Moon, Westcott, Oakland, Olds, Allen, Hupmobile, King, Mitchell, Chalmers and Hudson.

Some few cars use the down movement as in fig. 2: Haynes, Buick, Maxwell, Chevrolet, Ford.

Dodge, Marmon and Cadillac the levers are arranged differently, but principle is the same.

The Packard spark lever moves from the left, up, to advance, and the throttle from the right up, to open.

The Pierce spark and throttle lever movement is shown in fig. 10.

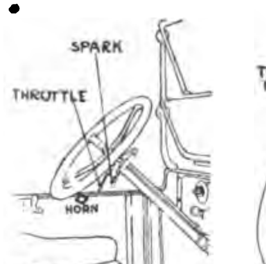
White spark lever moves down to advance. Throttle moves up to open.

Locomobile spark lever (54, page 500); when pulled as far back as it will go is fully retarded. When pushed forward, it is advanced. For driving between 15 to 45 miles advance the spark ¾ advance, below that speed retard to ½ advance. Above 45 miles, full advance. (see also page 497.)

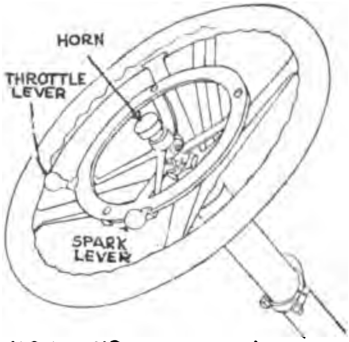
Franklin has but one lever (throttle) which moves up to open. The automatic advance of spark takes care of the spark advance. See page 249.

Where automatic spark advance is used, the spark lever is usually advanced ¾ of the way and the automatic advance takes care of further advance, at higher speed it is advanced full. Where automatic advance is used sometimes, there is no hand spark lever at all.

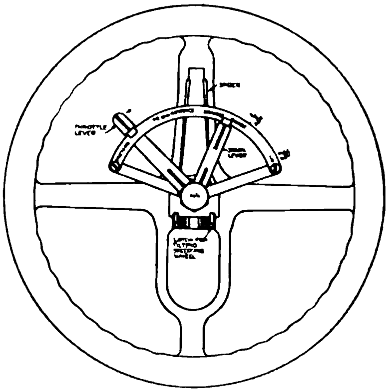
Accelerator: After engine is started, the throttle lever is opened just enough to keep engine from stalling and variation of speeds is made with the accelerator (see page 497, 154, 492). The spark advance is about 2/3 advanced.



DODGE - UP - to open & advance



MARMON - UP - to open & advance



Cadillac spark and throttle move from left to right to advance.

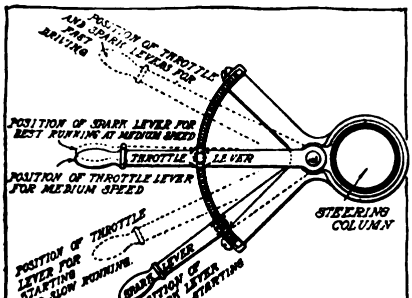


Fig. 10. Spark and throttle lever arrangement as used on the Pierce-Arrow, See page 500. Dotted lines show positions of spark and throttle levers in various running conditions.

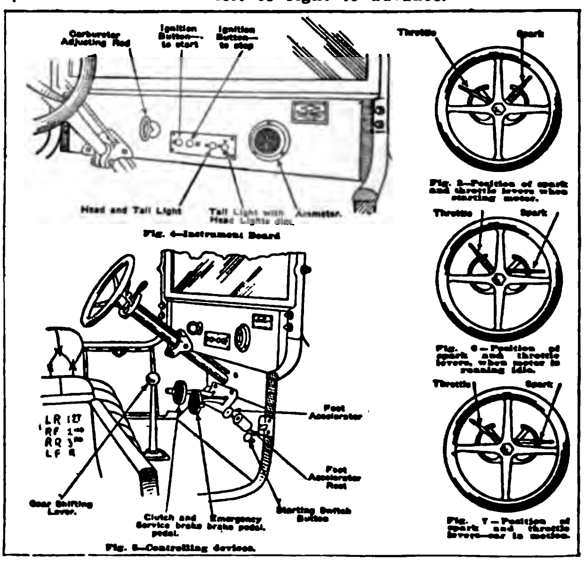
Ignition timing; C4—set magneto fully retarded, piston 1" after top; battery ignition; set breaker box ⅛" from full retard and piston on top. B4—set magneto retarded, piston 5/16" after top; battery ignition same as C4. A4—set magneto retarded, piston 1¾" after top; battery ignition ⅛" from full retard with piston ¼" after top.

Firing order, 1, 5, 3, 6, 2, 4. (see page 349 for electric system).



Chevrolet gear shift: LR—left rear; RF—right forward; RR—right rear; LF—left forward.

CHART NO. 213—Spark and Throttle Levers.

See page 499 "Willys-Knight;"—this illustration gives the average position of levers for different speeds.

Chandler.

Fig. 23—Chandler Dash and Control units—the gear shift movement is the S. A. E. standard 3 speed gear shift shown on page 490—which is used by most of the manufacturers, see page 542 for firing order.

CHART NO. 217—Dash and Control Units of Pierce-Arrow, Locomobile and Chandler, 1917-18.

*On the later model Pierce Arrow the switch (X and Y) are now two lever switches; ignition and lights; with starting button (U) mounted above the two levers and Klaxon horn button in top of steering column. Later models Locomobile and Chandler are practically the same as above.

INSTRUCTION No. 35.

RULES OF THE ROAD: Pointers on Driving. Traffic Regulations.

The driver of a car should be careful to observe the rules of the road, for damages are not so liable to be collected, if he can prove that he was where he should have been.

Throughout the United States, the invariable rule is to keep to the right; in England it is just the opposite.

The following is a fair example of traffic rules which may vary slightly, but practically represent the rules in different large cities.

*Street, Traffic and Parking Ordinances.

DEFINITIONS.

"Vehicle" includes animals that are led, ridden or driven and every horse-drawn or motor-driven conveyance except a street car. (Sec 1294. Rev. Code, 1914).

"Driver" includes the rider and driver of a horse, the rider of bicycles and motorcycles and the operator of any other vehicle. (Sec. 1294 R. C. 1914).

"Congested district" consists of the following described streets, to-wit: Third Street between Locust Street and Chestnut Street, Fourth Street between Washington Avenue and Chestnut Street. Broadway between Washington Avenue and Market Street. Sixth Street between Washington Avenue and Market Street. Seventh Street between Washington Avenue and Market Street. Eighth Street between Washington Avenue and Market Street. Ninth Street between Washington Avenue and Pine Street. Tenth Street between Washington Avenue and Pine Street. Market Street between Fourth Street and Eighth Street. Chestnut Street between Fourth Street and Ninth Street. Pine Street between Third Street and Tenth Street. St. Charles Street between Fourth Street and Tenth Street. Olive Street between Third Street and Twelfth Street. Locust Street between Third Street and Theresa Avenue. Washington Avenue between Fourth Street and Ninth Street. Grand Avenue between Lindell Boulevard and Morgan Street. (Sec. 1333 R. C. 1914) See map

"Street" designates every highway and place used by or laid out for the use of vehicles. (Sec. 1294, R. C. 1914).

"To park" means to stand or store any vehicle on a public highway when it is not being loaded or unloaded. (Sec. 1294, R. C. 1914).

AUTHORITY.

Drivers shall at all times promptly obey all reasonable directions of a police officer engaged in directing traffic as to stopping, starting, approaching or departing from any place; the manner of taking up or setting down passengers, loading or unloading goods in any place. (Sec. 1258, R. C 1914 amended by Ord. 30174).

LICENSE.

STATE LICENSE PLATES shall be conspicuously displayed and firmly fixed on the front and back of every motor vehicle, except motor cycles and motor tricycles, which shall display State License Plate permanently fastened to the back only (State Law, 1917)

License plates shall be kept reasonably clean (State Law, 1917)

LIGHTS.

MOTOR VEHICLES while on the public highways, whether in operation or otherwise from a half hour after sunset to a half hour before sunrise, and when fog or other atmospheric conditions render the operation of vehicles dangerous to traffic, shall carry at the front at least two lighted lamps, not exceeding 36 candle power each (except that motorcycles shall carry one lighted lamp) showing white lights visible at least 500 feet ahead and revealing objects 150 feet ahead, adjusted and directed so that on level ground the main shaft of light shall be projected straight forward, no portion of it being above the level of the lamp nor more than 42 inches above the ground. Electric headlights shall in addition, have their door glasses etched, ground or be so formed that the lighted filament shall appear blurred. (State Law, 1917; and Sec. 1314 R. C. 1914).

Red light on Rear. At all times when lights are required there shall be carried at the rear a lighted lamp exhibiting one red light, plainly visible for 500 feet towards the rear. (State Law, 1917; and Sec. 1315a, R. C. 1914).

Sidelights, or substitutes therefor, may be used with electric bulbs not stronger than 10 candle power each, provided the condensed light is projected forward and if possible downward, below the level of the lamp, and provided the glass openings emitting light are etched or ground as required of headlights. (State Law, 1917; and Sec. 1314a, R. C. 1914). Ground glass bulbs may be used instead of having the glass opening etched, ground, etc

Spotlights shall not be used on the public streets except in emergencies or when headlights are inadequate owing to rain or fog and then only providing shaft of light is directed well downward and at no time into the eyes of other persons. Outside of the city, they may be used if directed well downward and not into the eyes of other persons. (State Law, 1917; and Sec. 1315, R. C. 1914).

HORSEDRAWN VEHICLES from one half hour after sunset to one half hour before sunrise during the months from October to March, inclusive and from one hour after sunset to one hour before sunrise during the months from April to September. inclusive, shall carry at least one light showing white from the front and red from the rear, visible a distance of at least 300 feet. (Sec. 1308, R. C 1914).

LIGHTS AND WARNINGS UPON EXTENSIONS shall be placed when any part of the load projects more than five feet beyond the rear of the vehicle. Such extra light or warning must be placed at the extremity of the projection and be visible from both sides and from the rear. (Sec. 1311 R. C. 1914 and penalty Sec. 1312, R. C. 1914)

VEHICLE BEING TOWED shall have separately displayed thereon the lights required on vehicles of the class to which it belongs. (Sec. 1310 and 1312, R. C. 1914).

BICYCLES while on public highways, whether in operation or otherwise, at the times and under the conditions specified for MOTOR VEHICLES shall carry one lighted lamp showing a white light, visible at least 200 feet to the front, and also one red light or one red reflex mirror plainly visible from the rear. (State Law, 1917; and Sec. 1308, R. C. 1914).

COLOR OF LIGHTS. No vehicle shall show any other than white light to the front and red light to the rear. (State Law, 1917; and Sec. 1308, R. C. 1914).

RULES OF THE ROAD FOR VEHICLES.

HOW TO DRIVE. All vehicles shall be driven in a careful manner, with due regard for the safety of other vehicles and persons. (Sec. 1301, R. C. 1914).

RIGHTS OF VEHICLES. Two vehicles, which are passing each other in opposite directions, shall have the right of way, and no other vehicle to the rear of either of such two vehicles shall pass or attempt to pass such two vehicles. (State Law, 1917).

OVERTAKING, MEETING AND PASSING. If overtaking another vehicle (except a street car), pass on its left. (Sec. 1267, R. C. 1914). In meeting another vehicle, pass it to the right Keep to the right side of the street. (Secs. 1300 and 1266 R. C. 1914).

VEHICLES TO PASS OTHER VEHICLES—HOW—EXCEPT STREET CARS. A vehicle overtaking another shall, in passing, keep to the left, and shall not pull over to the right until entirely clear of it, nor shall it leave the line on the right unless there is a clear way of at least one hundred feet in advance on the left. (Sec. 1267. R. C. 1914).

RIGHT OF WAY. Vehicles in the service of the Police and Fire Departments and United States Mail, underwriters' salvage corps, emergency repair vehicles of public utility companies, and ambulances, when in the course of their regular duty, shall have right-of-way over other vehicles. (Sec. 1278, R. C. 1914). East and west bound vehicles shall have right-of-way over north and south bound vehicles. (Sec. 1250, R. C. 1914). Excepting where controlled by traffic regulations of a city, the driver of a vehicle approaching an intersection of highways shall yield the right-of-way to a vehicle approaching on his right. (State Law, 1917).

STOP BACK OF STREET CARS. The driver of every vehicle shall stop at the rear of any street car which has stopped to take on or let off passengers, and shall remain at a standstill until such street car has resumed motion; provided that on streets in the congested district vehicles may pass street cars so stopping if they clear the running board, or lower step by six feet. (Sec. 1283, R. C. 1914).

STOP BACK OF BUILDING LINE. When so signalled by traffic officer, vehicles shall stop back of building line, leaving the crossing clear for pedestrians. (Ord. No. 30174).

VEHICLE LIKELY TO DELAY TRAFFIC. No one shall drive any vehicle in such condition or so loaded as to be likely to delay traffic, or cause an accident. (Sec. 1285, R. C. 1914).

WIDTH OF VEHICLE AND LOAD. No person shall drive through the streets a vehicle the width of which, with its load, shall exceed ten feet, except on permit from the Director of Streets and Sewers. (Sec. 1287, R. C. 1914).

LEFT SIDE TO CURB NOT PERMITTED. No vehicle shall stop with its left side to the curb. (Sec. 1289, R. C. 1914). See Special rules for One-Way Streets and Alleys for exception.

STOPPING ALONGSIDE ANOTHER VEHICLE NOT PERMITTED. No vehicle shall stop abreast another vehicle lengthwise of a public street except in an emergency. (Sec. 1290, R. C. 1914).

SLOW UP ON APPROACHING A PEDESTRIAN. Driver of a motor vehicle shall slow up on approaching a pedestrian who is on the travelled part of the roadway and signal audibly. (State Law, 1917, see Secs. 1276 and 1277 R. C., 1914).

SLOW UP ON APPROACHING INTERSECTING HIGHWAY, CURVE OR CORNER. The driver of a motor vehicle on approaching an intersecting highway, curve or corner where his view is obstructed shall slow up so as to readily stop. (State Law. 1917 and see Secs. 1276, 1277 and 1301, R. C. 1914).

SAFETY ZONES. No vehicles shall cross or enter safety zones as designated by the signs. (See Secs. 787 to 789, R. C. 1914).

TURNING. A vehicle wishing to cross from one side of the street to the other in a business district, except in the congested district, shall go to the next intersecting street before making the turn. (See Secs. 1271 and 1272, R. C. 1914, and Sec. 1334 Cong. Dist).

Vehicle turning into another street to the right shall keep as near the right hand curb as possible. (Sec. 1269, R. C.. 1914). See Special Rules for One-Way Streets and Alleys for exception.

Vehicle turning into another street to the left shall turn around the intersection of the center lines of the two streets. (Sec. 1270 R. C. 1914). See Special Rules for One-Way Streets and Alleys for exception.

SIGNALS ON LEAVING CURB, SLOWING UP, STOPPING OR TURNING. The driver shall give an advance signal to those behind by holding out the hand or by some approved signalling device, so as to indicate intention to slow up, stop or turn. In approaching an intersecting street where other vehicles are approaching or where a traffic officer is located, the drivers of vehicles shall designate the direction in which they wish to proceed by signals or words. (Secs. 1273 and 1274, R. C. 1914).

BACKING. The driver shall give ample warning to those behind by hand or by some approved signalling device before backing and constant care shall be exercised to avoid a collision while doing so. (Sec. 1275, R. C. 1914).

*St. Louis Traffic Laws and Regulations as an Example. Compiled by Mr. J. F. O'Donnell, Atty., under direction of Mr. C. M. Talbert, Director of Streets, St. Louis, Mo.

—continued on page 503.

Safety First—Read and Remember.

The following is an advertisement in which Chicago manufacturers, public service corporations, financial institutions, insurance companies, firms and individuals co-operated. It speaks for itself.

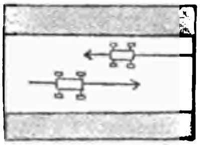

Fig. 1—Cars going in opposite direction; keep well to the right.

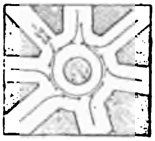

Fig. 2—On approaching a circle; arrows point the way

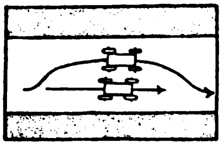

Fig. 3—One car passing another vehicle going in the same direction.

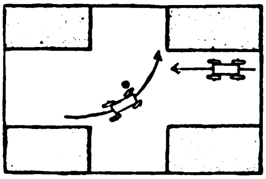

Fig. 4—In turning corners with a car coming, use signal with your hand to indicate the direction you intend to go and for him to slow up. Always observe a central point O in the intersection of streets and clear it when turning.

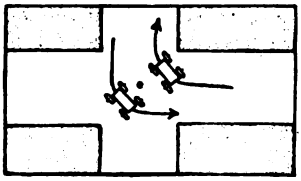

Fig. 5—The driver of a vehicle turning to the left from right hand side; should pass the center of the street intersection before making a turn. In case he wishes to make a right hand turn he should hug curb as closely as possible.

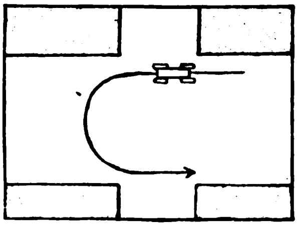

Fig. 7—Turning, go to the far corner; then make a wide swing to turn

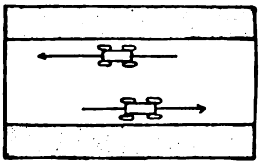

Fig. 6—In stopping, do not face car in wrong direction Stop with the right side of car to the curb

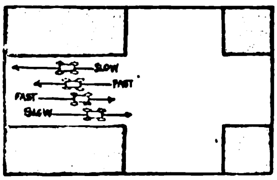

Fig. 8—Slow going vehicles; keep close to curb

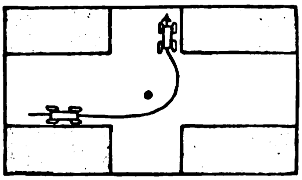

Fig. 9—How an auto should turn a corner

Don'ts for Drivers.

Don't approach street intersections at high speed.

Don't resent the traffic officer's directions—he is doing his best to prevent accidents.

Don't overlook the rights of the pedestrian—his life is just as important as yours.

Don't fail to give signal with hand when turning or stopping.

Don't drive on the left side of street or cut corners.

Don't permit your chauffeur to speed. You are just as guilty as he.

Don't use your big headlights—they blind other drivers and pedestrians.

Don'ts for Pedestrians.

Don't cross streets before looking both ways.

Don't stand in traffic route when waiting for street car. Remain on sidewalk or in safety zone.

Don't cross street except at the regular crossing.

Safety for Children.

Don't cross a street without first stopping and looking both ways.

Don't play in the stret, especially in one frequently used by automobiles.

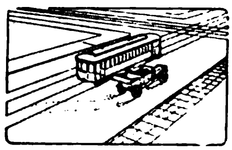
Don't steal rides by hanging on the back of wagons, trucks, automobiles.

Don't throw a stone or other missile at any vehicle.

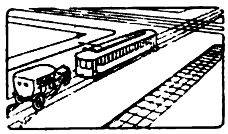
Don't use roller skates or coasters on the streets.

Don't ride on the left side of the street and near the curb while riding a bicycle—stay on the right side.

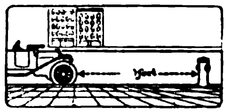
Don't catch on to automobiles when riding bicycle.



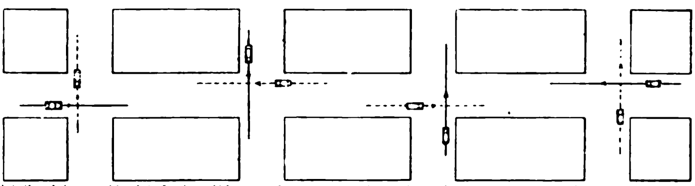
The right way to pass street cars is the safe way



Passing a street car at the left, a violation of the law



Cars must not be left near hydrants



It is the rule in many cities that when two vehicles approach a street intersection simultaneously, in the manner illustrated, the vehicle at the right, as indicated by the heavy lines, shall have the right of way, regardless of the directlon it is traveling

It is the rule in many cities that when two vehicles approach a street intersection simultaneously in the manner illustrated, the vehicle at the right, as indicated by the heavy lines, shall have the right of way regardless of the direction traveled.

CHART NO. 218—Rules of the Road in Driving Straight Ahead, Passing and Turning.

STOP ON APPROACH OF FIRE APPARATUS. The driver of a vehicle, on approach of fire engine or fire apparatus, shall immediately draw up said vehicle as near as practicable to right hand curb, parallel thereto, and bring it to a standstill. Street cars shall immediately stop between intersecting streets and keep stationary on the approach of fire engine or other fire apparatus (Secs. 1282 and 1281, R. C. 1914)

VEHICLES TO KEEP NEAR RIGHT HAND CURB—EXCEPTIONS. All vehicles shall keep to the right and as near the curb as possible, except when passing vehicles ahead. (Sec. 1266 R. C., 1914)

TAXICABS AND OTHER VEHICLES REGULATED BY PERMITS shall comply strictly with the provisions set forth in their respective permits. (See Secs. 525 to 554 R. C., 1914.)

NO ONE UNDER 16 YEARS OLD TO DRIVE. No one under sixteen years old shall drive any public, numbered, licensed or business vehicle on a public highway. (Sec. 1296, R. C. 1914)

NO CHAUFFEUR UNDER 18 YEARS OLD. No certificate of registration of a chauffeur shall be issued to any person under eighteen years old. (State Law, 1917).

KEEP TO RIGHT DRIVE ON DIVIDED PARKWAY. On a street divided longitudinally by a parkway vehicles shall keep to the right of such subdivision. (Sec. 1268 R. C. 1914).

VEHICLES—STOP WHERE—NEAR CURB. No vehicle, unless in an emergency, or to allow another vehicle or pedestrian to cross its path shall stop in any public street or highway, except near the right hand curb, and so as not to obstruct a crossing, and shall not stop or stand within the intersection of any streets. (Sec. 1292 R C 1914) See Reg. one-way streets.

ACCIDENTS. In case of an accident due to the operation of any vehicle, the driver thereof shall stop and render such assistance as he can, give his name and address to the person injured or to any other persons who question him, and report the same immediately to the Police. (State Law, 1917).

INTOXICATION. No person while under the influence of intoxicating liquor shall drive any kind of vehicle on the public highways (State Law, 1917).

PROCESSIONS. No vehicle shall be driven through a funeral procession except Police, Fire Department, Salvage Corps, emergency repair vehicles of public utility companies, United States Mail and ambulances, when on duty. (Sec. 1189, R. C. 1914).

OBSTRUCTION BY VEHICLES AND INTERFERENCE WITH STREET CARS. No vehicle shall so stand on any street as to interrupt or interfere with the passage of street cars or other vehicles. (Sec. 1325, R. C. 1914; see Sec. 1292, R C. 1914). This applies particularly to vehicles standing near the corner so as to interfere with street cars rounding curves.

NO AUTOMOBILE SHALL BE LEFT UNATTENDED WITH MACHINERY IN MOTION. No automobile shall be left upon any street unattended while any portion of its machinery is in motion. (Sec. 1291, R. C. 1914).

VEHICLES NOT TO OBSTRUCT MAIL BOXES. No vehicle shall be allowed to stand opposite a United States mail box so that convenient access thereto is obstructed. (Sec. 1326, R C 1914).

LENGTH OF TOW LINES. Any vehicle being towed shall be so connected as not to leave a distance of more than 12 feet between vehicles.

GLASS ON STREET, ALLEY OR DRIVEWAY. No person, firm or corporation shall throw or place any glass upon any public street, alley or driveway. Penalty up to $100 for each offense. (Sec. 1208 and 1209, R. C. 1914)

RULES OF THE ROAD FOR PEDESTRIANS.

OBSERVATION OF THE RULES. Pedestrians by observing the rules will facilitate the movement of traffic and minimize danger to themselves. While they have the right to cross the roadway in safety, it is intended, primarily, for vehicular traffic.

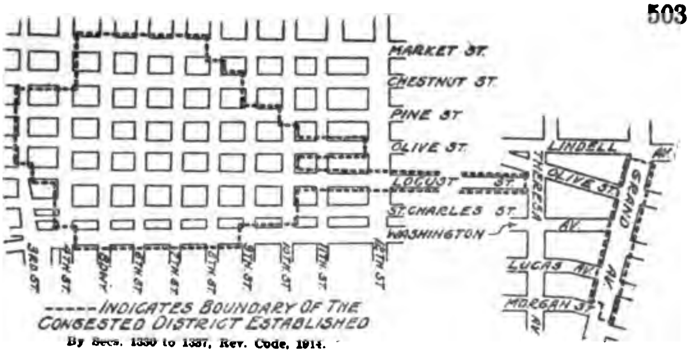
LOOK BEFORE STEPPING FROM THE CURB, first to the left and then to the right for vehicles.

USE THE REGULAR CROSSING, and cross at right angles and not in the middle of the block or diagonally at intersections.

STAND ON SIDEWALK WHEN WAITING FOR STREET CAR until the car approaches.

OBEY TRAFFIC OFFICER'S SIGNALS AND COMMANDS.

DON'T CROSS BEHIND STREET CARS. When alighting from street cars, be sure the way is clear before crossing behind car.



By Secs. 1330 to 1337, Rev. Code, 1914.

CONGESTED DISTRICT.

(See "Definitions" and Map for Boundary.)

Between the hours of 7 A. M. and 7 P. M. the following regulations shall be enforced in the "Congested District." (Sec. 1330, R. C 1914 and Sec. 1333).

NOT TO PARK LONGER THAN ONE HOUR. No vehicle shall remain continuously at the same place in the congested district for a longer period than one hour. Disabled vehicles and vehicles for public hire, operating under proper permit, are exempt. (Ord. No. 30405).

VEHICLES FOR ADVERTISING NOT TO STOP. Vehicles for display advertising or public inspection shall not stop within the congested district, except on direction of traffic officer or on approach of fire apparatus, and shall move at not less than three miles per hour. (Sec. 1330, R. C. 1914).

"NO PARKING" SPACES. The Director of Streets and Sewers is authorized to designate spaces on either side of any street where no vehicle shall stand for a longer period than is necessary for the discharge or receipt of passengers or freight and not longer than fifteen minutes while so engaged. These spaces shall be designated by official signs. It shall be unlawful for any person to place any sign designating any portion of a street as a place at which vehicles shall not be parked except the signs authorized as above (Sec. 1335, R. C. 1914).

ENTRANCE TO PUBLIC BUILDINGS. No vehicle shall park before any entrance to a building for a longer period than thirty minutes. (Sec. 1331, R. C. 1914).

COMPLETE TURN AT INTERSECTION PROHIBITED. No vehicle shall make a complete turn so as to face in the opposite direction on any street in the congested district, but such vehicle, in order to turn around, shall be driven around the block. (Sec. 1334, R. C. 1914). Owner or driver may be misdemeanant, under this section.

FIRE HYDRANT RESERVATION. No vehicle unattended shall be left standing at any time within 6 feet of a fire hydrant. (Sec 1330 (c) R. C. 1914).

SPEED.

Vehicles on the public highways shall be driven in a careful manner and at such speed as not to endanger the safety or injure the property of anyone. (State Law, 1917; Sec. 1301, R. C. 1914).

TEN FEET BETWEEN VEHICLES AT CROSSING WHEN PEDESTRIAN ABOUT TO CROSS. No person in charge of a vehicle shall allow same to come within ten feet of any vehicle in front of him when approaching and passing over a crossing when pedestrian is about to pass (Sec. 1276 R. C.. 1914).

SPECIAL RULES FOR ONE-WAY STREETS AND ALLEYS.

Sixth, Seventh, Eighth and Ninth Streets, and all alleys in the business district are one-way One-way streets have been designated to facilitate the movement of traffic. Vehicles move in the same direction as street cars and on the dead side. Parked vehicles stand on live side of street cars, leaving space for safety zones. Thus vehicle traffic is not interrupted by stopping while street cars take on and discharge passengers and the latter are not endangered by moving vehicles. In parking at an angle, autos are required to back in, thus the top when down overhangs the walk while if headed in, the tops of the larger machines would not clear the street cars.

SIXTH STREET AND EIGHTH STREET BETWEEN WASHINGTON AND MARKET SOUTHBOUND. Vehicular traffic shall move south on the east side of the street. Waiting vehicles shall stand on west side, facing south, at an angle of 30 degrees with the curb.

SEVENTH STREET, BETWEEN WASHINGTON AND MARKET AND NINTH STREET BETWEEN WASHINGTON AND PINE NORTHBOUND. Vehicular traffic shall move north on the west side of the street. Waiting vehicles shall stand on the east side, facing north at an angle of 30 degrees with the curb.

VEHICLES STOP WITH LEFT TO CURB. Since traffic is moving ahead on the left side of the street, vehicles may stop with left side to the left curb, long enough to load or unload, but if intending to park must take up position on the right-hand side of the street.

TURNING. In turning to the right into a one-way street the center line of the latter must be passed before making the turn. In turning to the left into a one-way street, the center line of latter must not be passed before making turn

ALLEYS IN BUSINESS DISTRICT. In all east and west alleys, vehicular traffic shall move west; and in all north and south alleys it shall move south.

SIGNS.

"SAFETY ZONES." (Secs. 787 to 789, R. C. 1914). These signs are placed to designate the space reserved for pedestrians waiting for street cars and through which vehicles must not be driven.

"CONGESTED DISTRICT" signs are placed at all street corners within the congested district.

"NO PARKING" signs are furnished and placed by the Department of Streets and Sewers on the curb to designate the ends of the space within which vehicles must not be parked, in accordance with the congested district regulations. (Sec 1335, R. C. 1914).

"ONE-WAY TRAFFIC STREET." These signs are placed at each street corner on a one-way traffic street, designating the direction in which traffic must move.

"IN" or "OUT" signs are placed at entrance to one-way alleys in the downtown district, to designate the direction of traffic through the same.

"SCHOOL ZONE" signs are placed on either side of and 100 ft. from school buildings as a warning to drivers to use exceeding care for the protection of children crossing street.

"ZONES OF QUIET" signs are placed in the neighborhood of hospitals and similar institutions, where particular care is to be exercised in preventing unnecessary noise. (Secs. 1196-1198, R. C. 1914).

PEDESTRIAN LINES. At certain street crossings in the downtown district white lines are marked on the roadway pavement, within which pedestrians are expected to stay when crossing the street.

EQUIPMENT OF MOTOR VEHICLES.

BRAKES. Adequate brakes must be provided and kept in good working order at all times (State Law, 1917).

WARNING SIGNALS. Every motor vehicle operated on the public highway shall be equipped with a warning device capable of emitting a sound adequate in volume to give warning of the approach of said vehicle Every person operating motor vehicle shall sound the warning device whenever necessary, but not at other times. (State Law, 1917; see Sec. 1323 and 1324. R. C. 1914).

MUFFLERS shall be attached to the engines of all motor vehicles and shall be of such capacity as to quiet the maximum possible exhaust noise as completely as practicable. (State Law, 1917; and Sec. 1317 to 19, R. C. 1914).

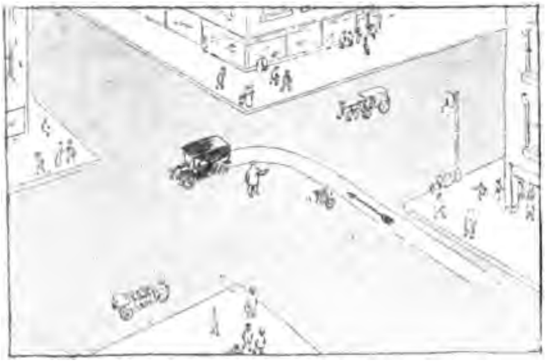
MUFFLER CUT-OUT shall be completely closed and disconnected from its operating lever so that it cannot be opened while said vehicle is in motion. No vehicle shall be driven in such manner as to produce unnecessary noise. (State Law, 1917; and Secs. 1317 to 19, R. C. 1914).

LOCKS. Motor vehicles should be provided with good and sufficient locks, installed in a manner that will allow the moving of the car, when necessary, by the Police and Fire Department.

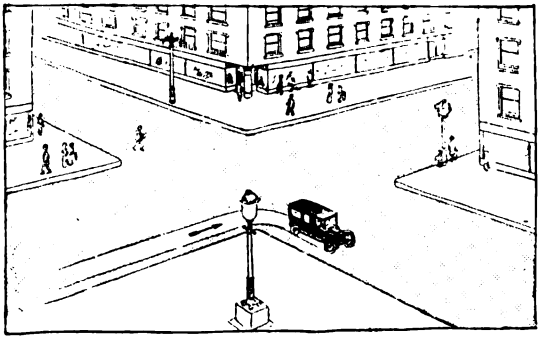
Traffic ordinances similar—are provided free to motorists in every large city. When touring, one should secure a copy for each large city he enters.

One way streets are usually those in which street cars run in one direction only. Alleys in business districts are also one way.

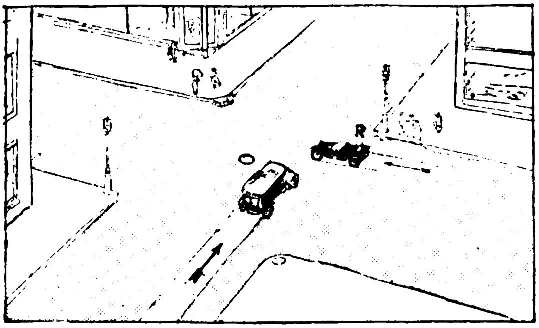
Section 1335, under "Congested District" above has been amended. For instance, "No Parking" space, would apply to other than congested districts, if in the judgment of the Director of Streets such spaces are necessary, for interest of a business firm in loading and unloading freight, etc.



When turning to the left—pass around the center of intersection of two streets.



When turning to the right keep near right hand curb.



On crossing a street—the right hand vehicle has the right of way.

Rules For Driving.

Approaching rail roads—In approaching a railroad crossing, especially if there is an incline or grade, the car should be dropped back into second speed and the approach made carefully, first to determine whether to make the crossing or not, and second, to be in position to accelerate your car suddenly with very little chance of stalling your engine.

Many accidents have happened because inexperienced drivers have become confused and stalled their engine. On noting the approach of the train, they have thrown on their power, or let in their clutch suddenly, with the result that the engine is stalled and it is then too late to move out of danger.

In crossing street car tracks and climbing out of ruts—skidding can be prevented and accidents avoided, also the life of your tires lengthened, if you will learn how to turn your car out of street car tracks and ruts. Make a sharp turn of your front wheel. Do not allow the wheel to climb along the edge of the rut and finally jump off suddenly, and do not attempt to climb out of these conditions at speed.

Rounding corners at speed—Driving a car around a sharp corner at twenty-five miles an hour does more damage to the tires than does fifteen or twenty-five miles of straight road work. This is an economical reason why one should drive around corners cautiously and slowly. The other reasons are obvious.

In passing a slower moving vehicle going the same direction, always pass on the left, so it is to your right. If you attempt to pass on his right, you may be run into the gutter. **In passing another car going the same direction, don't run immediately in front of it.** More accidents have resulted from this practice than in any other manner.

When a car comes up from behind, and shows signs of desiring to pass, give it the road by swinging to the right. Before starting to race it, remember that it is about the most dangerous thing that can be done, and that racing has caused many automobile accidents.

In passing street cars, never pass it on the left, but on the right—another car may be coming the opposite direction (if double track which is usually the case), you would then be bound to place yourself on the wrong side of the street.

If passengers are getting on or off cars—stop, don't crowd between them and the curb, its against the law in most cities. **Do not follow a car too closely**—it may stop suddenly, without warning.

Stop when there is an accident, whether it is your fault or not. Render all the assistance possible, and as a safeguard get the names and addresses of witnesses.

Excessive sounding of the horn is proof that the motorist is a novice. Sometimes in the presence of a frightened horse, it may be better not to use the horn at all. No accepted rules exist in regard to the meaning of horn blasts, but it is reasonable to assume that prolonged honking indicates that the car behind is going to pass and desires a clear road.

If you are driving in front of another signal to the party behind you as above when stopping, slowing down or turning.

Remember: That a nervous driver may pull the wrong rein. That a pedestrian cannot make up his mind in a hurry when he wants to cross the road. That it is your business to avoid danger, not the other man's. That the road is free for all, and that it pays to be courteous.

Use of head lights: Do not use the electric head lights turned to the "bright" position when approaching or passing a car or other vehicle on a narrow road, unless you are traveling in the same direction. The light confuses them and may result in a serious accident.

Headlight Courtesy on the Road.

You know how very difficult it is to see when you are approaching another machine with glaring headlights. You are simply blinded and cannot tell whether you are running off the road, are too close to the oncoming machine or are striking obstructions. It is a peculiarly helpless feeling to be directing a car when confronted by the other fellow's glaring lights in this way.

If your headlights are on, he is in just the same predicament, however, and it is the least either of you can do to dim the headlights while passing. This is a safety factor as well, for it protects both from running into one another or off the road.

In most states a law prohibits the use of glaring headlights—see page 438.

CHART NO. 219—Rules For Driving. Signals for the Motorist Behind.

INSTRUCTION No. 36.

CARE OF CAR: Pointers on Driving, Washing, Polishing, and Cleaning Car. Home Made and Other Polishes. Painting a Car at Home. Systematic Car Inspection. Shipping.

General Pointers on Driving and Care of the Car.

The driver must keep his eyes and ears open, watching the other occupants of the road as well as the running of the car.

The ear is the best judge of the running of the engine, as it shows any defect by a change in its steady throb. With practice it becomes easy to recognize a new noise and the cause should be located and remedied at once. A squeak or rattle that comes at regular intervals may be located in one of the revolving parts, and if not regular, it comes from something that is not revolving—the springs, brakes or similar part.

Irregular running of the engine may not be serious, but rather the result of a rough road or loose ignition connections. **Knocks or pounds should be located at once,** for they may lead to serious breakdown.

Know Your Car.

Remember that in the care and operation of a motor car, much must be left to the judgment of the operator, who should study the construction of his car and thoroughly acquaint himself with its mechanism, the functions of its various parts and the why of everything connected with it.

Learn the speed of which the car will take a turn on mud or wet asphalt, without skidding or side-slipping, and never exceed it. Learn the grade of a hill that the car will climb easily, and on steeper grades do not wait for the engine to labor before changing the speed.

Learn the turn that it will make for every position of the steering wheel, and always make the broadest turns that the width of the road will permit. A sharp turn is more likely to strain and injure the tires, running gear and steering mechanism, than a broad turn, and if the car is speeding, more likely to cause an upset.

Learn the distance that the car will travel before refilling the tanks—not from the catalogue, but from your own experience, so that hold-up on the road for supplies may be prevented.

Learn the rapidity with which the car will pick up speed after a slow-down, as it will help when running through traffic, or when it is necessary to dodge another vehicle.

It is important to learn the shortest distance in which the car can be stopped for its different speeds, and the exact amount that it slows down for each application of the brakes. Learn to use the brakes so that the motion becomes automatic, and can be done without wasting time thinking about it. Learn to judge distance, and the speeds at which the car travels; ability to estimate speeds may prevent arrest.

Learn to recognize the noises of the engine when it is running smoothly; the click of the valves, the hum of the timing, pump and magneto gears, the puff of the exhaust, so that unusual noises may be easily recognized.

Learn the feel of the compression, by cranking the engine, so that leaks may be detected. Learn the effort required to push the car on a smooth floor by hand, so that a binding brake or a tight bearing may be felt. In short, get in tune with your car—be part of it—make it part of you; that is, if you want to get good service from it, and save on the repair bills.

Something to Remember.

The flashy driver, who makes quick turns and sudden stops, attracts attention, but ruins the car. The more smoothly a car is operated, the longer it will last, and the less often it will get out of order. Driving is not a thing to worry about, but to be taken easily.

Easy turns, gentle stops, the running of the engine as slowly as possible for the speed desired, proper adjustments, and constant care, mean long life to the car, and freedom from trouble.

When the engine is not acting right, do not rush in and re-adjust the ignition or carburetor without first being sure that the trouble has been correctly located. Throwing the carburetor out of adjustment on a guess makes it all the harder to get going again, for its re-adjustment must be added to the trouble already present. An automobile is not difficult to handle, but neither is it so simple that brain work is not necessary. Get all of the facts possible before doing anything to the mechanism—the noise that the engine made in stopping, the way it stopped, the reasons for the unnatural noises, and the bolts from which nuts may have dropped off. An automobile is constantly in a state of severe vibration, and almost any part is liable to work loose when least expected.

Some accessories are convenient, and others are nuisances. Do not load the dash up with devices that are not of practical use, for they only add to the parts that must be watched and taken care of. Provide the car with a good horn, and use it well when necessary, but never needlessly.

The lubrication is important and must be watched carefully; it takes only a little running without oil to cut the cylinder walls and piston rings. Excessive oil in the crank case means fouled spark points, and should never be permitted, however, it is better to have too much than not enough.

In running, keep to the right, and in meeting another vehicle turn farther to the right, so that it will have room to pass. (See charts 218 and 219).

In passing a vehicle going in the same direction, pass so that it is on your right, and do not swing back to the right side of the road too close in front of it. The other vehicle may speed up as you pass, and be closer than you realize.

Get thoroughly familiar with the different speeds, so that there will always be time to stop when necessary. Keep your eye on the people alongside of the road, for they may start to cross without warning. Children are liable to run out of a gate or cross the road, when they are least expected. Cross roads and cross streets must be watched, for vehicles or people may come along them.

It is dangerous to run over a dog, for the steering mechanism may be broken or the car upset. It is far safer to slow down when one is barking in front of the car than to try to push it out of the way.

Blow the horn when approaching a turn in the road, for another car may be coming. Do not run on the low speeds if it is possible to run on the high.

Save the Tires.

If a tire blows out, do not jam on the brakes—cut off the power and let the car coast to a stop. Jamming on the brakes might cause a skid, and that would fatally ruin the tire.

In crossing loose or broken stone as on a new road, do not drive the car over, but get up speed and as it strikes the stones throw out the clutch so that it will coast. If the car has not enough momentum to cross, let it go as far as possible before again throwing in the clutch. **Driving across sharp stones forces the wheels to grind against them, while if the car moves without being driven, the tires roll over the stones, and are not so liable to injury.**

Jamming on the brakes grinds the tires, and wears them as nothing else does. Letting in the clutch quickly, so that the wheels spin before taking hold of the road, has the same effect.

Tires that are not sufficiently inflated will rim cut and are more liable to puncture than if blown up hard. **Oil rots rubber;** therefore, keep the tires clear from it. If they get oily, wipe them with a cloth soaked with gasoline.

If the car is to be idle for a week or more, jack up the wheels to take the weight from the tires—it will be better for them.

Rusty rims cause rim cuts; therefore, keep them smooth. When rim rusts, scrape them or rub with emery cloth and give them a coat of shellac or lead paint to prevent them from rusting again.

In applying new tires, put them on the rear wheels, moving the half-worn one to the front wheels—this will give them a longer life. In applying a single new tire, put it on the right hand rear wheel, as this is the one that has the hardest work, and needs to be stronger than others.

An extra inner tube should always be carried, ready to insert in case of a puncture. Take out the old tube and put in the extra, then have the damaged one vulcanized. It does not pay to cement a patch on a tube; have it vulcanized. The best plan is to have demountable type of rims and carry a complete extra tire inflated, ready to mount on wheel.

Skidding ordinarily occurs only on slippery surfaces and in rounding turns at high speed. In skidding, the wheels of the car slip on the ground, especially on wet asphalt, although the car will occasionally slide on dry surfaces, like sand, loose gravel, etc. See page 495 for "skidding."

A Few Words About Gasoline and Fire.

Gasoline must be handled with care and common sense. It is dangerous if handled carelessly but need not be so if the operator uses judgment. Gasoline vaporizes easily and as the vapor is heavier than air, it sinks to the ground.

When filling the tank, be sure that there are no open lights near, or a fire. If the tank is to be filled at night, don't use a lamp, use a pocket electric flash lamp instead. Have a funnel for gasoline and do not use it for anything else. Also see index for "gasoline."

***In case of fire, do not try to put it out with water,** for the burning gasoline will float and spread the fire. Always keep a

*Fires are usually caused by dripping gasoline from carburetor and a stray ignition spark. Be careful the carburetor does not drip. **See also pages 158 and 161.**

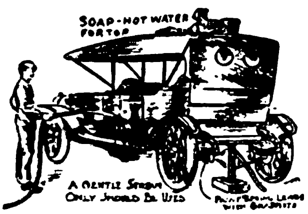
pail or two of sand handy and smother the flames with it. In case of fire, the **first thing to do if it is possible, is to turn off** the supply cock from the tank to the carburetor, and then push the car away from the blazing gasoline on the ground. Do not let a pool of gasoline drip from the carburetor when priming it as a chance short circuit may give a spark that will set it on fire.

***Engine bearings:** After an automobile has run a great many miles the crank shaft ("main") bearings wear and allow play as also do the connecting rod bearings. The first evidence of a worn bearing is an "engine knock." **To test bearings** grasp the fly wheel and jerk it vigorously; if play is discovered it is an indication that the bearings should be "taken up." The bearings are "split," that is, arranged in two halves bolted together, see page 74. Between the halves, "shims" (very thin strips of metal) are placed. As the bearings wear, one or more shims can be removed and the bearings drawn up.

See also pages 203, 793 and 651; "running in a new engine" and page 489 for "running a new car."

Tighten bolts and nuts: It is very important that you should go over your car periodically and tighten up all loose nuts and bolts. This should be taken care of especially during long hard tours and about once a month under average driving conditions.

Washing Car.



First dust off the car and top, then wash car using only clear water. If soap is used, get a good carriage soap that has no alkali in it. **If it contains alkali it will take off** the varnish.

Mud should not be rubbed off for the varnish would be scratched. Let the water run gently out of the hose (using no nozzle) and flow over the mud, so that it washes away slowly.

The full force of the water may be used to remove mud **from under side of fenders; but not from any varnished part.** If a hose cannot be used, pour the water on so that the mud is carried away. Dry mud is more difficult to remove, but if the varnish is to be kept bright use only the above method, and take time to it.

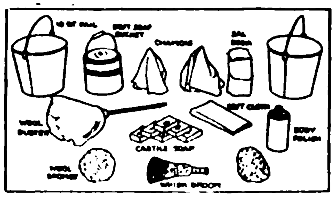
When the body is clean, go over it with a soft sponge using plenty of water and dry it with soft, clean chamois skin or wash leather. It is advisable to have a sponge and chamois skin for the running gear and a separate sponge and chamois skin for the body.

After having washed the body it should be gently dried with a piece of clean chamois skin. Wring out the water from the chamois as the car is wiped with it.

For removing grease, a sponge with castile soap and tepid water should be used and then body polish applied.

A car ought to be washed and chamoised off immediately if rained upon, otherwise spots will remain if left to dry. See Instruction 45 for "a home made washer."

Supplies for cleaning the car: Two good clean soft "wool" sponges, two ten-quart pails, several clean soft chamois, a quantity of canton flannel, a quantity of ivory or pure castile soap, clear running water, a soft wool duster, gasoline for use in extreme cases.



The two sets of pails, sponges and chamois are recommended so that the pail and sponge used for the first washing, may be kept separate from those used in the final washing.

Washing Radiator.

When it is necessary to clear the radiator spaces of accumulated mud you should flush the radiator from the rear, not from the front. In that way you avoid getting water into the magneto, which is often short-circuited when moisture enters it.

Sponge off your Hood.

Particular attention should be given to the hood after the car has been run in a heavy rain, inasmuch as after a long run it becomes fairly hot and if rain-drops are left to dry upon it they will stain it much more than the body. The car should be washed down at once, or if this is not possible, the hood should be sponged off and wiped dry immediately.

A good body polish will remove grease and rain spots from a hood or body.

Body, Metal and Glass Polishes.

Polishing body, removing rain spots and grease: A much recommended polish is made by mixing the following ingredients; turpentine 1 gallon, paraffine oil 1 pint, oil of citronella 3½ ounces, oil of cedar 1½ ounces. This should be applied **after**

*See also, pages 640 and 641.

the car is washed and dried. Apply this with soft, clean cotton waste and rub dry with a clean flannel cloth. If not rubbed dry the dust will collect. This preparation in most cases will remove rain spots and grease.

Another method is to use a mixture of boiled linseed oil and turpentine, applying it sparingly and rubbing absolutely dry. The use of these polishes will restore even an old car to a degree of brightness that will surprise you.

Another body polish that is highly recommended is made by using 1 gallon of soft water, 4 ounces of ordinary soap, 1 pound of white wax in shavings. Boil well and add 2 ounces of pearlash. This may be diluted with water and laid on with a paint brush, then rubbed off with a cloth. Another formula often used is 3 ounces of shellac, ½ ounce of gum mastic and 1 pint of methylated spirits of wine, dissolved. In our opinion however, better results will be obtained by using some one of the varnish polishes that are on the market and can be found at almost any hardware or paint store.

A good cleanser for enameled parts of the car when parts are greasy and very dull, may be made of the following:

One pound of washing soda crystals to one pail, or 2½ gallons of water. This should be very briskly applied with a soft rag. Then polish with canton flannel.

The solution, before applying, should be carefully inspected to see that all crystals have been dissolved, as any crystals remaining will scratch the surface.

This solution should be used only on enameled parts of the car as it will ruin varnish or paint. The enameled parts of the car are the radiator, radiator splashers, bonnet, front and rear fenders, gasoline tank, tire carriers, steering column, shifter lever, black engine parts and enameled part of lamps.

Brass.

Any good brass polish will work satisfactorily. All these preparations contain some fine abrasive, for which reason care must be taken not to let the polish come into contact with the varnish body surfaces.

Nickel-Plated Parts.

All nickel plated parts may be cleaned with regular silver cleaner paste. Use only the softest flannel rag or chamois to rub with.

Do not clean lamp reflectors except when absolutely necessary and then use Putz pomade, applied with a very soft clean chamois skin. Reflectors are often silver plated and are very easily spoiled by frequent polishing.

Nickel trimmings should be rubbed over with an oily rag; that will keep them bright without polishing. When going out for a run in damp or rainy weather it saves labor to give the brass work a light coat of vaseline to protect it from tarnishing, and put rubber bags over the lamps. When there is little time to give to cleaning the brass work, paint it with black or colored enamel which looks better than uncleaned brass.

Metal and Glass Polish.

Mix one part wheat flour, five parts of dry powdered fire or potter's clay and used with a damp woolen cloth. This will be found the finest polish ever used and is cheap. It can't be beaten for cleaning fly specks, grease, paint and other stains from glass or metal.

To Clean Glass and Reflectors.

For cleaning glass — windows, wind shields, lamp lenses, mirror lenses, etc.— there is nothing better than a mixture of half alcohol and half water, which readily will clean off dirt and leave a bright polish. With a soft cloth, or a piece of tissue paper, the work can be done expeditiously. See page 435 for cleaning and polishing reflectors. Putz pomade applied with a very soft, clean, chamois skin is also excellent for cleaning reflectors.

**Cleaning Tops.

To clean top—outside. A top that has been in use for some time can be cleaned by using the following mixture:

½ pint raw linseed oil; 4 cups water; ½ cup turpentine. Apply with clean rag and rub dry.

A dressing for leather tops: A very good receipt for the purpose: One part liquid asphaltum to two parts castor oil, to which add ½ ounce of ivory black to each pint of the mixture. Apply with a soft brush. This dressing is excellent for a rubber top.

Mohair tops should be frequently dusted and brushed off. Pantasote tops and curtains are best cleaned with a soft brush dipped in water in which a little ammonia has been added. Afterwards rub dry. Never attempt to clean top and curtains with gasoline or kerosene.

Do not fold the top until it has become thoroughly dry, because any moisture remaining in the folds is apt to cause mildew, beside making the top leaky and unsightly with spots. When the car is not used for some time it is best to open the top, which keeps it well stretched and smooth.

If top is mohair, a pail of tepid water and a bar of castile soap should be used. Place soap in pail and work with the hands until a good lather is obtained. A large clean sponge is dipped into the water and top thoroughly washed.

If top is dirty use broom first. After cleaned with soap go over it with clear water so no alkali spots will appear.

To prevent rain or snow from sticking to glass: mix about 2 oz. glycerine with 1 oz. of water and a dram of salt. Apply to wind shield with cheese cloth—wiping up and down or in a vertical direction.

For Cleaning Engine—see index. **See also index; "Repairing Tops."

Cleaning Leather Upholstering.

Do not use gasoline in cleaning leather upholstery. Plain water with a little ammonia will remove the dirt, and a brisk rubbing with a clean woolen or flannel cloth will do the rest. For still more careful treatment, use a regular leather dressing on all leather.

Receipt for a dressing for leather upholstering: Raw linseed oil and turpentine mixed in proportions two of the former to one of the latter, is a time honored formula.

For cleaning cloth upholstery use clear water and a mixture of ¾ of an ounce of common salt and two ounces of either grain, or wood alcohol, simply rubbing the cloth with a sponge dampened in the above mixture.

To remove ordinary dust from cloth upholstery, beat cushions and backs lightly with stick or carpet beater, then remove dust with whisk broom or brush. (The vacuum plan is best.)

Grease or oil may be removed by the application of a solution of luke warm water and ivory soap, applied with a woolen cloth. Any of the approved methods for cleaning woolen cloth may be used with success on this upholstery. Gasoline and benzine have a tendency to spread instead of remove the dirt. We, therefore, do not recommend their use although they work no injury to the fabric.

*Suggestions for Repainting Car at Home.

In some cases the car owner may feel disposed to do some of the work himself, and then pass it on for the professional painter to put on the finishing coats.

He may, for example, give the car as thorough and complete a washing up as the painter will do. Then by getting the car up on stout wooden horses, so that he can work under it conveniently the grease and dirt may be removed from the chassis. This is a somewhat smeary job but anyone who isn't afraid of work can save some money by doing it. Saturate the greasy parts with one-third turpentine and two-thirds kerosene or crude oil, and let the applied mixture stand for several hours to soften up the hardened oil and dirt.

Then take a one-half inch putty knife and a couple of mowing machine knives and some pieces of coarse burlap and proceed to cut and scrape the accumulations off and wipe the parts up. It may take two or three applications of the oil and turpentine mixture, and a lot of rubbing with the burlap to get the surface clean, but it is all necessary work.

If the surface is worn and the paint beaten off, and the bare metal or wood disclosed, these pieces will need touching up with a paint mixture containing at least one part raw linseed oil and two parts turpentine. Mix thoroughly, some ground white lead and lamp-black and add a little at a time to the oil and turpentine. Apply with a small round brush.

Next get some dry white lead and a small quantity of finely ground whiting, and using one part of the whiting to two parts dry white lead, knead it to a good working body in equal parts of coach japan and rubbing varnish. Then with your putty knife, putty up all the holes and surface fractures, filling them smooth and level with the surrounding surface. While this class of work is somewhat difficult to do well, with care and some practice it may be taken care of.

If the surface is in a condition suitable to sand paper, apply the color without any further surfacing. The professional painter may then, if so desired be called in to sand this putty and the surface down smooth and apply a coat of color to the car. If any striping is to be applied, the lines may be run on this coat of color after which apply one or two coats of varnish, according to the class of finish desired.

In case the car needs simply a coat of varnish, with perhaps a few worn or bruised spots touched up with a bit of color, it should first receive a thorough washing and cleaning. The body surface will need going over with water and pulverized pumicestone to lay down the gloss and fit it for the varnish. Then touch up with the color where necessary, and apply a coat of body finishing varnish. Likewise, give the chassis a stout coat of varnish.

In this connection, it may be stated that the amount and kind of work to be applied to the car depends altogether upon the condition of the surface at the time the work is to be done, as it naturally also depends upon the sum of money the owner wishes to expend upon the work. Generally speaking, if the car is kept well varnished, it will not need heavy painting repairs only at long intervals.

**Painting Radiator, Engine, Cylinders, Manifold, etc.

To paint radiator, mix 3 oz. boiled linseed oil, 4 oz. lamp black, 1 oz. turpentine and thin down with turpentine to the proper consistency. In applying, the radiator must be either dipped into solution (in this case a great deal more must be mixed), or sprayed (see page 194 and index; "painting radiator,") or the radiator can be placed on boxes, face up and with a thin mixture as above, applied plentifully so it will run through the cellular parts of radiator. A camels hair brush can be used to reach places not covered.

†To paint cylinders, mix 8 oz. white lead in oil, 6 oz. boiled linseed oil, 2 oz. turpentine and ½ oz. of lamp black. If too heavy thin down with turpentine. This will make a gray paint and sufficient for 6 cylinders.

Aluminum mixed with bronzing liquid can also be used.

To paint intake manifold—use regular aluminum secured at any drug store.

To paint exhaust manifold—use aluminum. No paint has as yet been found which will remain on hot exhaust pipes; here is a recipe suggested:

Heat proof paint—use two parts of black oxide of manganese, three parts of graphite and nine parts of Fuller's earth, thoroughly mixed, to which add a compound of 10 parts of sodium silicate one part of glucose and four parts of water, until it is of such consistency that it may be applied with a brush.

*****Tire paint, liquid rubber** is a preservative and beautifier of tires. It gives the tire a white coating. It is made of pure unvulcanized rubber in solution. It can be applied with a brush and if used at regular intervals, it is claimed it will prolong the life of the tire because it penetrates and runs into any small cuts or holes and seals them over, thus in a measure preventing moisture from reaching the fabric. It is also suitable for golf balls, rubber mats, and a highly satisfactory rust preventive for rims. Secured at supply houses.

See index for these various subjects. **See also index; "top repairing." †See also page 588.

A very satisfactory tire paint for finishing the inside of a tire after repairing may be made by mixing thoroughly one gallon gasoline, one half pint C-35 cement, 1½ pounds soapstone and ½ pound whiting. Many successful repairmen are using this formula with the best of results.

***See page 571; how to make paint to paint inside and outside of tire.

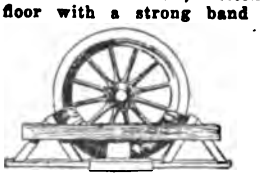
Pointers on Shipping an Auto.

An auto will only be received for transport by freight either crated or set up. The usual method in shipping by freight is to ship it complete and run it right into the car; see that the railroad company block the wheels so that the auto will not pitch forward or backward. It is also well to see that the machine is braced from the side.

Get a clear bill of lading from the railroad company so that you have something to secure damages with in case of car being smashed. It is well to box the cushions and all loose parts separately. The charge for conveyance must be ascertained by the railway company

Place the vehicle in the car parallel with the sides; and see that the front wheels are in line with the back wheels. Wrap the lower third of the tires with burlap to prevent chafing; and set the brakes.

To block wheels, fasten each wheel to the floor with a strong band of canvas or several layers of burlap of the width between two spokes. Secure the band to the floor on each side of the wheel with blocks 2 by 4 by 12 inches. Place these blocks parallel with the wheel, using plenty of nails or spikes.



Use blocking in front and behind each tire one-third as high as the diameter of the wheel, and at least one inch wider than the tire. Fasten this securely to the floor and tie together with one or two-inch lumber from block to block. Have the blocking of sufficient width so that the boards used to tie blocks together will clear the tire at least one-half inch on each side.

In packing the auto, empty the gasoline and water tanks and disconnect the batteries, if electric cars, remove batteries.

The tires should be tightly inflated; and the edges of the boards and blocks next to the tire should be rounded or beveled, so that if they should become deflated or in any way come in contact with the boards or blocking, they will not be so liable to chafe. Place covering over the vehicle to keep off dust. Also remove lamps to prevent damage to them.

Freight cars should be carefully inspected to see that they are fit for loading. If there are nails or other projections in the floor or sides of the car they should be removed. If the roof appears to be leaky, or its fastenings for doors, both end and side, are not complete or ample, the car should be refused and a car suitable for loading demanded. Failure on the part of the shipper to do this renders him liable for the damages resulting from having loaded the vehicle in a car manifestly unfit.

Daily and Periodical System of Car Inspection.

Look to the following every few days:

(1) Fill gasoline tank. The funnel that is used for gasoline should never be used for water, lubricating oil, or anything but gasoline.

(2) Fill radiator.

(3) "Tickle" or prime the carburetor, to make sure that the float is free and the gasoline flowing. At the same time inspect the connections of the gasoline line for leaks and loose joints.

(4) Test the batteries, and see that the storage cells are properly filled with electrolyte. (see page 454.)

(5) See that the ignition is working properly and no miss.

(6) Lubricate the engine—See page 204. Make sure that the oil has not drained out of the crank case.

Beginning at the front of the car and working to the rear, screw the grease cups down slightly, filling those that are nearly empty.

While doing this, watch for loose nuts, and for parts that may be out of place, loose or in need of attention.

Be particular to keep the steering mechanism in good condition, and plentifully lubricated.

(8) Pump up the tires, and keep them pumped up. For pressure to use see tire subject.

(9) See that the tools, supplies and extra parts are on board.

(7) Test the brakes, (very important.)

When accustomed to it, this system will not require much time and it will result in the condition of the car being under observation at all times.

The above points should be observed for every run, but others should be attended to from time to time.

Look to the following about every week or every 1000 miles:

(1) When the car has run 1,000 miles, the crank case should be drained and washed out with kerosene. See "cleaning crank case," page 201.

Grit and dirt will work in and thicken the oil, and must be removed.

(2) Drain and wash the change speed gear case.

Constant use will grind particles of steel from the gears, and cause rapid wear.

(3) Fill the gear case so that the smallest gear dips into the oil about a half inch. See page 203.

(4) If the differential runs in oil, wash it and renew the oil two or three times a season; if it is packed with grease, one filling a season is sufficient. (see page 205.)

(5) Every 2,000 miles, take off the wheels, clean and examine their bearings, and repack with lubricant, being careful to readjust them correctly.

††Inspection Before a Long Tour:

(1) Wash and polish the car.

(2) Drain and flush out the radiator; put in fresh water.

(3) Clean and inspect the engine; change the oil in the oiling system, after draining old oil. See pages 200 and 201.

(4) Clean and adjust the clutch.

(5) Clean the gearset and add new lubricants.

(6) Clean and lubricate the universal joints.

(7) Clean, adjust and lubricate rear axle.

(8) Clean and adjust the brake—see index.

(9) Inspect and adjust the wheel bearings.

(10) Clean, inspect, adjust and grease the steering mechanism.

(11) Inspect the tires, and have cuts or injuries repaired.

(12) Clean out the gasoline tank and line, especially the strainer.

(13) Clean out engine, put in fresh oil and clean carbon—see pages 200 and 201, also index.

(14) Inspect the ignition wiring and storage battery and clean distributor points and interrupter.

(15) See that wheels and axles are in proper alignment.

(16) Adjust the carburetor and see if well tightened to manifold.

(17) Fill the radiator with an anti-freezing solution (if cold weather). See page 198.

(18) Examine and test the storage battery—see page 450.

(19) Test the compression of your engine—see index.

(20) Tighten all spring bolts and nuts.

††See instruction 37 for "Necessary" Accessories for Touring.

INSTRUCTION No. 37.

ACCESSORIES; TOURING: Necessary Accessories. Desirable Accessories; Speedometers; Horns, etc. Touring Equipment. How and What to Cook. Lincoln Highway. Transcontinental Tour.

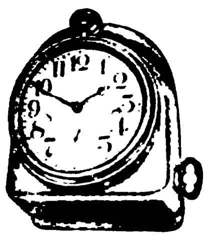
**Concerning Accessories and Equipment.

To differentiate between the accessories and spare parts actually "necessary" on a car, and those which are really only luxuries or "desirable" accessories, one has to have used them all under varying conditions and over extended periods to gain a knowledge of the desirability of each and an intimacy with their general utility.

Many a novice having unfortunately got into the clutches of an unscrupulous dealer, has bought nearly every fitting on the market being assured it is the right thing for an up-to-date car to be so equipped. Poor man! He finds it expensive work, and if the brass cleaner says little, he thinks a lot. In the beginning, be it understood that this article is primarily and exclusively intended for beginners, for I neither claim nor pretend to be able to teach the "old hands" much, as they, no doubt like myself, have learned these things for themselves.

Necessary Accessories.

‡**The necessary equipment for a car should consist of:** Lamp globes or bulbs, horn, tire tools, tire repairs, extra tire and tube, tool kit, jack, tow-rope, top, windshield, speedometer, bumper, hydrometer, odometer and a good clock.



Automobile clocks are made in many designs by Waltham Watch Co., Waltham, Mass. Note the "O" on dial. A red signal will appear every 8 days which is a notice to wind.

Though the clock is the last on this list it is very necessary, and it should be of the best and well built to stand vibration. As cars are driven in all seasons of the year the clock should have a compensating balance so that it will not be affected by extremes in temperature.

Experienced automomile drivers advise a clock to do away with the inconvenience of referring to their watch when clothed for cold or stormy weather as a few seconds necessary to do this might result in an accident to the machine or passengers.

Necessity of a speedometer. A speedometer is necessary in testing a car to learn its speed capabilities under various conditions—in order to time trips over various distances—to avoid violation of the speed limit laws, the penalty for which is arrest and fine.

Purpose of a speedometer. The speedometer for automobiles is an instrument for measuring and indicating—in miles per hour—the exact speed at which a car is being driven. The number of miles per hour shown at the dial of the speedometer is the actual speed at which the car is traveling at the instant of indication. For this reason the numbers shown constantly change as the car is driven faster or slower.

†**Necessity of an odometer.** The odometer is necessary in auditing the cost of operating and maintaining a car. It enables the owner to tell how much gasoline is used per mile—how much his tire expense per mile amounts to—how much mileage he gets out of his car. Thus it enables the owner to make comparison of the cost of operating and maintaining his car, with the cost of operating and maintaining a car of another make. The recording and re-setting features of the trip register part of the odometer is a necessity in following a guide book when touring.

Purpose of an odometer. The odometer (combined with the speedometer) is an instrument for measuring and recording—in miles and tenths of miles—the distance a car travels in making a trip. It also records the entire distance traveled during an entire season.

Purpose of a grade indicator. The grade indicator sometimes combined with the speedometer, is an instrument for indicating the exact grades of ascents or hills negotiated by the car. This instrument would come under "desirable" and not "necessary" accessories, see also page 539.

In selecting lamps or lighting outfit, I would insist on electric light equipment with a first class lighting battery and lamps with adjustable reflectors and non-glare headlight lens, if car is not already equipped.

I would also insist on a good **jack,** not the average, as usually included with car, but a good one. The Hartford, Buckeye or Badger.

A bumper will often save the radiator and is quite often placed on the rear of car as well as in front.

A motometer (as shown on page 188), should be on the radiator of every car.

*See page 349, for description of an electric clock. ‡A gauge to indicate quantity of gasoline in tank per page 823, would be considered as necessary.

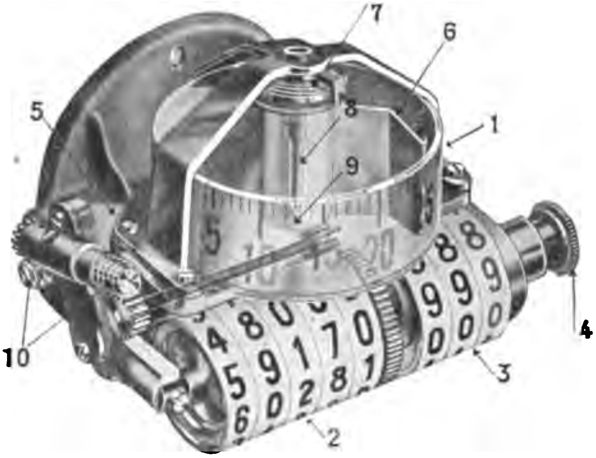
**For accessories to sell in a garage and equipment of stock room—see Instruction 45.

†The odometer is usually embodied in the same case with speedometer—see next page.

*Brief Description of Van Sicklen Speedmeter

The Van Sicklen speedmeter is an instrument which calibrates an air current and translates the result into miles per hour. The air circulator consists of two intermeshing aluminum gears housed in a chamber in which there are two openings, one from the outside and away from which the gears rotate, the other opening conducting the air into the speed dial chamber where the air is directed against a light vane attached to inside of speed dial.

The speed dial is an inverted aluminum cup mounted on a pivot set in jeweled bearings. The amount of air directed against the vane in speed dial is governed by the speed at which the air circulator is driven by the flexible shaft. The speed dial when the car is at rest is held at zero by the action of a nickeled steel hair spring.



Mechanism of the Van Sicklen Speedmeter and Odometer.

Illustration to the left shows the odometer and a phantom view of the speed dial.

1—Aluminum speed dial.
2—Records mileage for the season.
3—Records mileage for each trip.
4—For resetting trip register.
5—Case containing air circulator gears.
6—Vane inside of speed dial.
7—Hair spring holding speed dial in position.
8—Pivot of speed dial.
9—Jeweled bearings in which pivot of speed dial is set.
10—Gears driving odometer. Tenths of miles are recorded on dial at the extreme right.

Checking a Speedometer.

A simple test worked out by Mr. S. T. Williams of Motor World is shown in table below and as follows:

When the drive is from front wheel, jack up wheel. A chalk mark is then placed on rim of wheel and wheel turned as fast as possible.

At a signal, one person reads the speedometer, and another counts the revolutions for one minute as timed by a stop watch, or second hand of a watch. The number of revolutions of the wheel, and the speedometer reading at the start and finish are noted. (By adding the two speedometer readings, and dividing them by two, the average speed as recorded by the speedometer is determined.)

The actual speed may be obtained from the chart in fig. 5. Supposing the revolutions in the minute to have been 94, a horizontal line is followed until it meets the slanting line representing the diameter at the front wheel. Dropping down vertically, the speed is seen to be 9.6 miles per hour—which should correspond to the speedometer readings. If carefully made, this test is quite accurate, and requires little time.

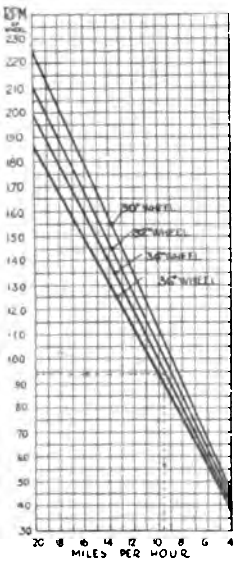


Fig. 5

Troubles

The indications of trouble are dial or pointer vibration, or failure of the instrument to register. Starting with the road wheel, examine the parts as per fig. 3. Begin with 1. The head (7) is the last part to inspect.

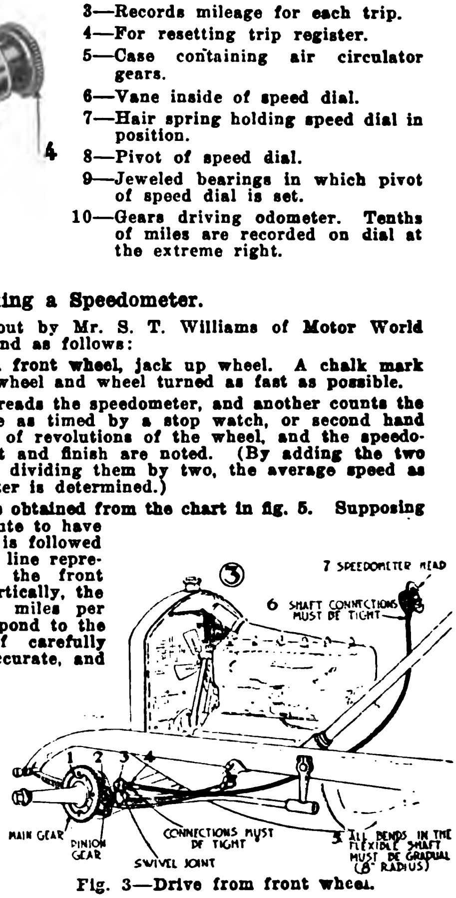

Fig. 3—Drive from front wheel.

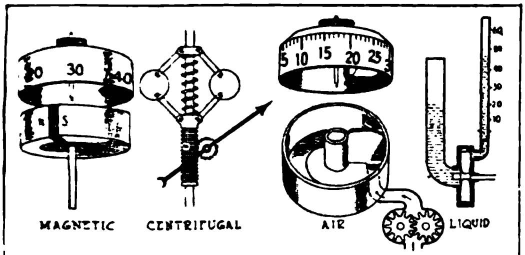
CHART NO. 220—Van Sicklen Speedmeter. Transmission Shaft. Checking a Speedometer For Accuracy. Speedometer Troubles.

On all Stewart speedometers the space between the main gear (1—fig. 3) and the pinion gear should be 1/16". Also note that the main gear (fig. 4) should have twice the number of teeth that there are inches in the diameter of the tire—see page 513. ***The Van Sicklen term their make of instrument a "Speedmeter"—otherwise term** "Speedometer" is always used.



The four principles of speedometer operation: Magnetic, in which a revolving magnet exerts its drag on the dial; centrifugal, in which revolving weights supply the energy due to centrifugal force; air, in which a current of air flows against a vane carrying the dial, and liquid, in which a column of liquid is lifted a height proportional to the speed of pump drive

Speedometer Principles.

The magnetic principle as indicated in Stewart-Warner and American Ever-Ready instruments, utilizes a revolving magnet positively driven from the car wheel or other part. The magnet exerts its influence on a metal part which is separated from it by an air gap and which in turn is connected with the indicating mechanism. The metal part is generally aluminum, as the inertia of the part must be kept as low as possible to make the speedometer quickly sensible to speed changes. A feature of the magnetic design is that the travel of the dial bears a direct ratio to the speed of travel of the magnet, and in order to compensate for changes in the drag due to temperature differences, a compensating unit is fitted.

Centrifugal control as utilized in speedometers is very much the same as that on a fly-ball engine governor. Standard, Johns-Manville, Sears-Cross, Corbin-Brown, Hoffeker and Garford use this principle. Weights are mounted on the revolving shaft by bell crank levers which allow them to travel further from the axis of the shaft as the speed of the drive increases. The centrifugal force of the weights increases as the square of the velocity of the shaft, meaning that at four times the speed, the force doubles.

This tendency of the weights to fly from the axial center of the shaft under the influence of centrifugal force furnishes the basis of the indicating needle movement. An ingenious feature in centrifugal design is that although the movement of the weights would naturally vary as the square of the speed, the levers or cams governing the movement are so calculated that calibrations on the dial are uniform or nearly so. Another feature which is carefully watched is the balance of the weights. The governors are made very sensitive so that even at low speeds the correct rate of travel may be indicated.

The air principle is used on one make, the Van Sicklen, which is described in chart 220.

Liquid or hydraulic principle: One instrument, the Veeder, which employs the hydraulic system, uses a centrifugal pump which is connected with the drive and which lifts a liquid to a height proportional to the speed of the drive. The tube in which the colored liquid is lifted is calibrated to register speed. See illustration.

Speedometer Drive Methods.

Front wheel drive: The speedometer can be driven from the front wheel (fig. 3, page 512 and fig. 4, this page) or off the transmission shaft as per fig. 5. The usual plan is to drive with gears.

Transmission drive: Instead of placing the speedometer drive on the front wheel which has been the standard former method, it is now quite often placed just rear of the transmission, on transmission main shaft. Fig. 5 shows how the driving gear is attached to the front of the forward universal joint. The swivel joint and gear section are clearly depicted. Other manufacturers are now adopting a set of gears inside of the transmission case, to drive the speedometer shaft.

Ratio of Gearing.

Ratio of gears for speedometer when driven from front wheels is found by doubling the diameter of tire and this gives the number of teeth necessary in the large **driving or road wheel gear.** For example a 30x4 tire would require a 60 tooth gear, etc. **Driven pinion** (small one) on all Stewart-Warner speedometers, for front axle drive have the same number of teeth, viz., 16, and drive through a 2½ to 1 swivel joint reduction.

The gear reduction in the swivel joint is mounted close to the driven pinion, as shown in figs. 4 and 5, and when installed on the left hand wheel, a swivel joint is used which reverses the direction of rotation.

Calibration: The Stewart-Warner speedometer flexible shaft, travels 1009 revolutions per minute when the car is traveling 60 miles per hour.

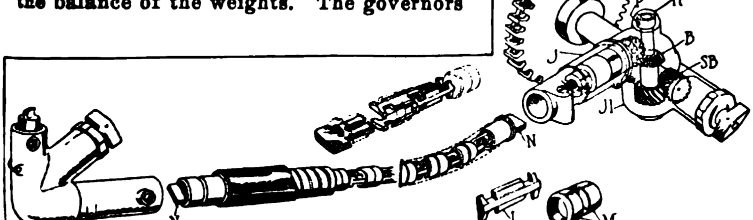


Fig. 4—Showing the flexible shaft together with other fittings, including swivel and angle joints

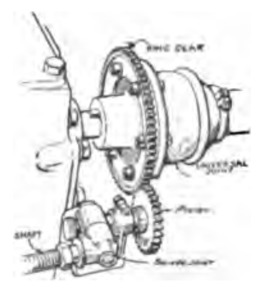

FIG 5 STEWART SPEEDOMETER PROPELLER SHAFT DRIVE

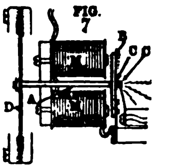
On the Waltham, which is illustrated above, (to the left), the flexible shaft is made up of a series of links, L, which are held in position by a series of steel collars M.

CHART NO. 221—Speedometer Principles Exemplified; Magnetic, Centrifugal, Air and Hydraulic.

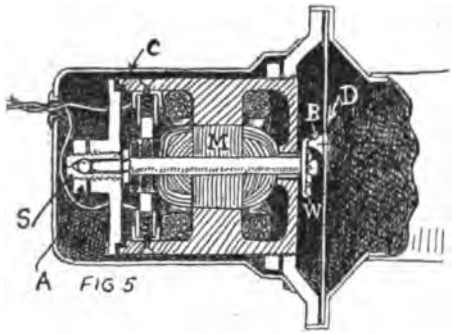
The Electric Horn.

There are two types, the vibrator type and the electric motor type.

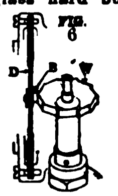


The electric vibrator horn, fig. 7: There are no revolving parts. The magnets (M) cause the vibrating spring (B) to strike the adjustable rod (A) which is attached to diaphragm (D) and breaks contact at points (C C). The construction of the vibrator is similar to an electric bell as is also the adjustment. The idea being to adjust vibrator (B) in relation to rod (A) to obtain a greater or less number of vibrations (similar to fig. 1, page 234) which increases or decreases the sound.

Points (C C) should be of iridium platinum, else will wear down and stick. Amperage consumed is 4 to 6.



The electric-motor horn, fig. 5; consists of a small electric motor with armature (M), field winding, commutator and brushes. When armature revolves the glass hard toothed wheel (W) rubs the glass hard button (B) which is riveted to a diaphragm (D)—see figs. 5 and 6. It is from this diaphram that the sound is obtained.



The voltage required for Klaxon horns is 6 to 8 volts. A storage battery or 6 to 8 dry cells can be used.

The amperage or current consumption is fixed for each size of Klaxon horn as stated under illustrations.

If in testing horn, as per page 418, it is found that the current or amperage consumption is greater than the fixed amount, then it is likely due to dry or dirty bearings, commutator and brushes, caused by instrument not receiving the proper lubrication.

Connections can be two wire or grounded, per page 515.

*To Adjust the Klaxon Horn.

To adjust 20L, fig. 1; loosen the lock nut (A), start the current by pressing the push button. While it is sounding twist the motor case until no sound is heard except the buzzing of the motor. Continue twisting, in either direction, until note is loud and clear. When note is as desired tighten lock nut.

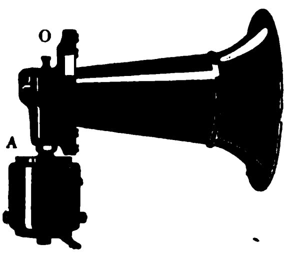


Fig. 1. Klaxon 20L uses 7 amperes.

To adjust the Klaxon 12-L and Klaxon-6, figs. 2 and 3, loosen the screws and remove cover (C). You will find a lock nut (A), fig. 5. While motor is running adjust screw (S) until the note is as desired. This action forces the armature shaft with its wheel (W) against the button (B). Replace cover and tighten screws.

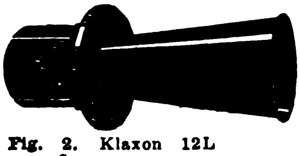

Fig. 2. Klaxon 12L uses 8 amperes.

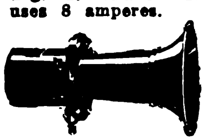

Fig. 3. Klaxon-6 uses 5 amperes and Klaxette not shown, 3 amperes.

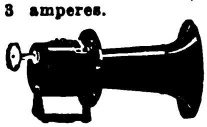

Fig. 4. Klaxon-3, hand type. Klaxon 88 type is same except it has a vertical push rack.

To lubricate; clean and lubricate commutator once a month as follows: With a dry cloth wipe commutator clean. Apply a little vaseline with a clean cloth. Use thin oil in winter. Apply this to commutator. The slightest film is all that is necessary. Every three or four months a little vaseline should be applied to toothed wheel (W). Oil shaft bearing once a month. On the Klaxon 20-L oil once a week through oil hole (O), fig. 1. Give two drops of cylinder oil.

Miscellaneous Accessories.

Fig. 4—The Buell compression whistle, screwed into cylinder in place of relief cock, operated from seat. Mfg'd by Buell Mfg. Co., Chicago.

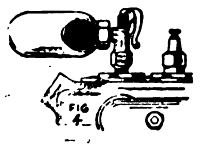

Fig. 3—A mirror useful for seeing car behind.

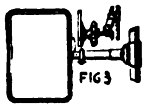

Fig. 5—A bumper will save lamps and radiator in case of collision. Should be on rear as well as front of car—(see page 736).

Fig. 6 — Tonneau wind shield, mfg'd by J. H. Tonneau Shield Co., 1777 Broadway, N. Y. A very desirable accessory, useful for winter or summer.

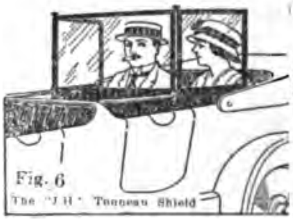

Fig. 6 The "J H" Tonneau Shield

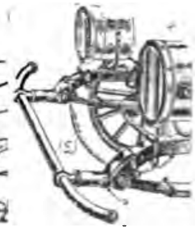

**The Magnetic Gasoline Tank Gauge.

These gauges are made for either pressure or gravity-feed tank; the amount of pressure makes no difference. The principle of the "Triumph" gauges is simplicity itself. A hollow metal float (F), (fig. 2), tested to one hundred pounds pressure, is threaded upon a gun metal bronze ribbon (R), which is suspended from the top of the tube and to which a permanent magnet (M) is attached. See p. 162, 823.

The bronze ribbon passes through a tube in the center of the float.

As the float travels up and down inside the tube of the gauge with the rise and fall of the fluid in the tank, it is turned by a spiral cut (C) in the tube. This naturally causes the metal ribbon to make a turn, also turning the m a g n e t which exercises its power through the solid head of the gauge, and turns the magnetic hand on the face of the dial.

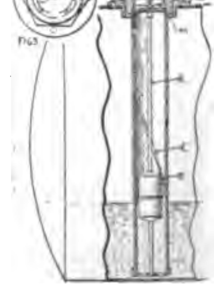

CHART NO. 222—The Electric Horn. Miscellaneous Accessories.

*See page 418, testing an electric horn. Write Klaxon Co. Newark, N. J. for instruction pamphlet on adjusting and caring for the Klaxon. **See page 823 for the "Gasograph," a very necessary accessory.

**The desirable accessories are such as; shock absorbers, which will save their cost in time by preventing broken springs and vibration and jar to the car (see page 26). The greatest shock when going over rough places on the road is during the rebound. The shock absorber absorbs this rebound motion and also prevents broken springs. See index "shock absorber."

A mirror on windshield so placed that the driver can see behind him, is another desirable accessory, as is also a mechanical tire pump. An electric hand lamp with several feet of lamp cord—for exploring around the engine or car—which attaches to the dash light socket by removing the bulb, is also very handy.

A tonneau windshield as per fig. 6, page 514 might be termed a necessary accessory.

Lack of space prohibits the enumerating of other desirable accessories both wise and otherwise.

Signal Alarms.

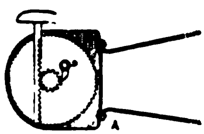
There are a variety of devices properly designated as signal alarms including: bells, bulb horns, electric horns, exhaust whistles, compression whistles, etc.

In the early days the mechanical electric bell, operated by the foot, was the applied method for warning the pedestrian—possibly this was not necessary as the cars in those days made sufficient noise to warn a block ahead.

Then came the bulb horn, but the old style bulb horn has about seen its days. It is seldom used, because of its difficult method of bulb operation and getting out of adjustment at the reed.

The compression whistle is the type shown in fig. 4, chart 222. It is desirable where there is no battery or where the battery is not of sufficient size to operate an electric horn. This type of alarm is very popular and saves battery current.

The exhaust horn or whistle was used extensively at one time, but is now seldom used.



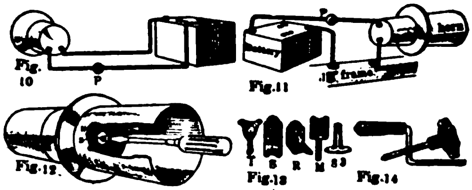
A
HAND
ACTUATED

The hand operated horn, as per fig. 4, is not desirable for two reasons: one is as per above and the second it is operated by hand at an inconvenient place. It is too near driver, whereas it ought to be nearer the front of car. When side curtains are down the result is, the noise is thrown inside of car instead of outside.

The vibrating type of electric horn is similar to a vibrator on an electric bell. Instead of the clapper striking a bell, it strikes against an adjustable rod, which is connected to a diaphragm (D), as explained in fig. 7, chart 222.

†**The motor type of electric horn** consists of an electric motor of small size with its armature and winding (M). On the end of the armature shaft a case hardened steel rachet wheel (W) (see figs. 5 and 6) strikes against a hardened steel button (B) on the diagram (D). The motor horn is the more desirable.

Construction of the electric motor horn; there are two types. The vibrator type of horn as shown in fig. 7, chart 222, and the motor type, figs. 1, 2, 3, 5 and 6; fig. 4 is a hand operated type.



Wiring on electric horn can be either "two-wires." fig. 10, or "grounded" return, fig. 11.

Fitting the electric horn to a car; a horn ought to be placed on the opposite side from driver and far away, in front of car if possible. The reason is, the noise is then away from occupants of car and the signal is placed where it is most effective, usually under the hood, to the front.

Adjusting a Stewart electric horn, fig. 12, is very simple. Always lock screw (3) with nut (N) after adjusting.

Horn brackets fig. 13 are for automobile use and are arranged so that horn can be mounted at different angles. M and 83 are for motor boat use. American Electric Co., Chicago, supply brackets.

Handles for hand actuated horns (fig. 14) can be had of some of the horn manufacturers,—suitable for long continued blasts when used on boats.

*A Transcontinental Tour—The Lincoln Highway.

The transcontinental tour is now comparatively easy and decidedly worth while to anyone who can possibly arrange to take it. I say "now," because such has not been the case in the past. Until very recently, a trip across the continent has been more or less of an adventure, a somewhat hazardous as well as an expensive and lengthy undertaking, requiring some measure of endurance.

Frank Trego in writing an article for Motor Age gives some very interesting data on touring. This article,—a part of which we give—was printed in Motor Age, some time ago, and is reproduced on following pages. —continued on page 517

*For a shorter tour, the reader can go over the lists on pages 517 to 520 and select what he thinks will be required.

**Lamp lens which are not glaring are necessary in most States. †See page 418 testing electric horn.

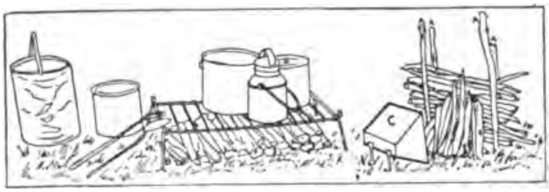


FIG.5 COOKING FIRE   FIG 6 BAKING FIRE

Fig. 5—Explains the method of making a cooking fire as described in Mr. Trego's instructions on pages 519 and 520, note the iron rods (B) and iron frame with cross rods.

Fig. 6—Explains the method for building a baking fire which must be high. Note the sticks (A) are of green material whereas the burning material is dry. C is the patented baker, made of aluminum.

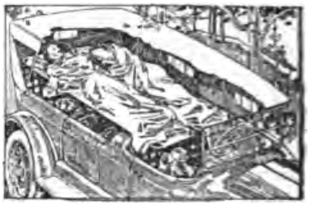

Fig. 22.—The Auto-Kot Co. manufacture a very serviceable and compact adjustable cot which can be placed on the top of rear seat, and front seat of a 5 or 7 passenger car. It can be folded in a very compact form and placed back of the front seats. (Peoria Auto-Kot Co., Peoria, Illinois.)

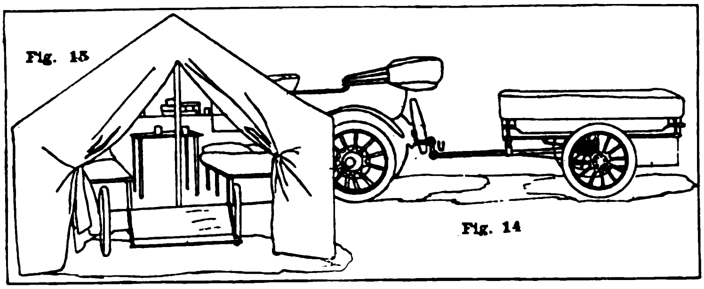

Fig. 15   Fig. 14

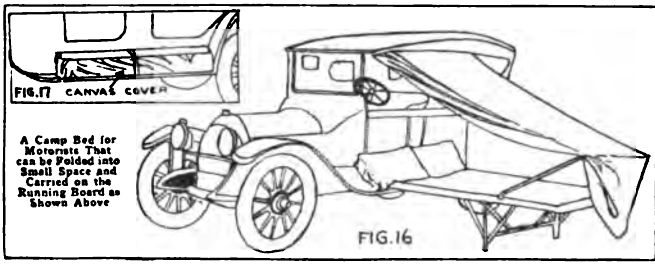

FIG.17 CANVAS COVER

A Camp Bed for Motorists That can be Folded into Small Space and Carried on the Running Board as Shown Above

FIG.16

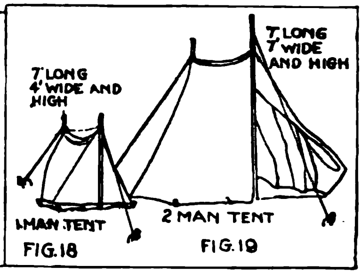

FIG.18   FIG.19

Fig. 14—Pictures a new idea of camping. A trailer (fig. 14) is carried with you and it is stated it will travel 50 miles per hour along with car. The tent and all parts are placed into this trailer.

Fig. 15—Shows the tent when removed from trailer and trailer used as the floor, and tail gate of trailer is utilized for a step. This outfit is made by the Auto-Kamp Equipment Co., Saginaw, Mich.

Fig. 16 shows another principle. Note the compact form of the outfit (fig. 17) when placed in box on running board and covered with canvas.

Fig. 18—Explains Mr. Trego's method for erecting tent as explained on page 517. The one man and two man tent is shown. Note the bottom of tent itself is used to hold the sides. This tent made of balloon silk can be swung between two trees or poles.

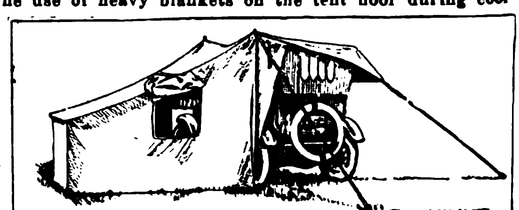
Fig. 20.—To use your watch as a compass: Point the hour hand of your watch to the sun at any time of the day, then lay the watch flat in your hand. A point midway between hour hand and 12 on dial will be due South.

Another outfit shown below: The tent has a floor 8 feet square which is sewed in. An extension of about 2 feet on the front edge of the floor can be fastened over the running board of the car. The front wall of the tent is 7 feet high and extends over the top of the car when the tent is pitched in this way, or it may be used as a straightfront for the closed tent when the car is not attached.

Two 7-foot poles prevent undue strain on the car top. The poles were cut with slip joints to be of proper 4-foot length to carry on the running board. The side walls have extensions of about 10 inches on the front edges to fasten to convenient places about the car, making a tightly closed tent in case of storm or cold wind. One side wall has a window, and the other has a door.

The rear wall is about 3½ feet high and was kept at a convenient height by its location near a fence, tree or other object to which ropes could be attached.

The tent was made of khaki at a cost of $18. Folding camp cots were used. The use of heavy blankets on the tent floor during cool weather was preferred to the cots. The tent was adapted to an Overland by a 6 inch flap sewed to the front wall to make sure of protection for the car. The size given is suitable for a car having a 7½ or 8-ft. top



This shows the arrangement of the tent in relation to the motor car. The tent can be used also without being attached to the car

—continued from page 515.

One can drive for nearly 2,000 miles across the country without once being more than half a mile from the familiar red, white and blue Lincoln Highway markers.

The only thing which might make a coast-to-coast automobile trip a hardship, would be a lack of proper equipment and perhaps the wrong time of year.

The greatest asset on a trip of this kind is "common sense." The next greatest asset is "efficient equipment."

The time required for the trip, with easy driving, will be nineteen days, driving approximately ten hours per day. This will make an average of approximately eighteen miles per hour, during the driving time.

Dress: White collars and cuffs are impossible in camp and soiled linen looks a thousand times worse than a flannel shirt. The khaki and flannel are much more welcome in a hotel.

Make ready before starting—not after. Fit yourself as well as your car.

The tent: If a one person affair where two sleep together—a balloon silk tent, 7x7x7 feet, A-shaped with water proof canvas floor sewed in, and loops along the ridge to tie rope when stretched between trees or in using poles. (See fig. 19, chart 228.)

The one person tent, (fig. 18,) called the **Trego tent** can be A-shaped, 7 feet long, 4 feet high by 4 feet wide, with a ridge rope sewed on and extending about 10 feet beyond each end. Floor, water proof canvas sewed into the sidewalls which hang over slightly.

At the head end is a little window covered with mosquito netting sewed in, and outside of this is a curtain which may be raised and lowered at will from the inside of the tent. At the foot are two flaps, overlapping each other when closed, and equipped with snaps and rings for fastening either open or closed. Sleep with the flaps and window of your tent open unless it is storming. A rope loop is attached to each corner for stakes, but, as a rule, the stakes will not be necessary, as the bedding holds down the floor.

This tent may be slung between two trees. If not used in this manner, the ropes at each end should be led over 4-foot stakes of some kind and the corners of the tent must then be staked down, so that the walls will act as cross pieces to keep the end poles upright.

This size tent will take blankets folded once over, and all of the extra clothing, etc., can go under the blankets at head and serve as a pillow.

The blankets are to be pinned across the foot of the head end, with horse blanket safety pins, procurable at any harness store, spacing them about 8 inches apart. There should be 2 pair of heavy blankets and one cheap cotton quilt. Fold this last mentioned over once and place under blankets to serve as a mattress.

Always keep a small whisk broom handy.

Sleep with clothes on, unless weather is warm, simply remove your shoes, leggings (use only canvas leggings, not leather), hat and handkerchief.

Camp location. Pitch where natural drainage will carry water off in case of rain. In the forest, cut a lot of small pine branches, no thicker than your finger, and rip-rap these with the stems to the foot, making a pad the full width of your tent, and about a foot thick, before you lie upon it. If there are no trees to furnish this, dig a trench about 3 inches deep by 8 inches wide just where your hip will come when you lie upon your side. This will add wonderfully to your comfort.

It makes no difference how the tent is placed, except do not get the foot or open end toward the wind.

Protection from the wind; try to get the camp out of the wind, on account of cooking. Along side of the woods is much better than in them, on account of the mosquitoes, flies, bugs, etc. Get near running water, if possible, although by carrying a 5 gallon milk can on running board you are independent.

Drinking water: Should be selected and carried in a 5 gallon milk can which can have a wood circle placed on running board to hold in place and straps made on the order of a harness over same. Don't be dependent upon other water—keep a supply on hand.

***When stuck in mud:** If the rear wheels are stuck in the mud, dig holes in front of the front wheels for them to fall into to give the initial start, and, if the car does not continue, then block the rear wheels instantly and repeat the operation. Place brush in front of the rear wheels and turn them as slowly as possible to keep from churning. If one rear wheel is on good road, try putting on the handbrake fairly tight to destroy the action of the differential, or fasten the mired wheel so that it cannot turn, and the other wheel will do the work and slide the mired wheel along the ground.

The instant you realize you are getting stuck in sand or mud, stop right there and look over the situation, instead of fighting the car and burying it deeper and deeper.

Start early and stop before dark to select the camp site.

Use the windshield up to keep the hot, dry air from burning your face, and have the top up all of the time for like protection.

Get all of your guide books before you **start.**

In asking directions, always apply to a garage or livery stable, but do not depend upon farmers, as their knowledge of the road does not extend very far.

If a party of four, let one do the cooking, another gather fire wood, another put up the tents, and the fourth go over the car with oil can and turn up all grease cups, adjust brakes, etc.

The Car Kitchen.

This outfit is designed for four people and weighs about 10 pounds. All items marked ‡ may be purchased at Von Lengerke & Antoine, Chicago, or Abercrombie & Fitch Co., New York, and the unmarked items may be obtained at almost any store dealing in such goods.

1 Arizona camp grate, 24 by 12 ins.‡
1 Set pot hooks.‡
1 Aluminum folding baker, 8 by 18 ins.‡
1 Canvas case for above baker.‡

The following Armorsteel pieces of cooking outfit may all be purchased at above mentioned firms.

1 Frying pan, 9⅝ inches wide, with patent handle.
1 Cooking pot, 9⅝ inches wide.
1 Cooking pot, 8⅛ inches wide.
1 Cooking pot, 7¼ inches wide.
1 Coffee pot 6⅝ inches wide.
4 Soup bowls, 4⅝ inches wide.
5 Cups, 4 inches wide.

Don't use aluminum cups.

6 Plates, 8⅝ inches wide.
4 Forks, with four prongs, 7¼ ins. long.
4 Knives, 8⅝ inches long.
6 Teaspoons.
2 Cooking spoons.
1 Carving knife, 10¼ inches long.
1 Sharpening stone.
1 Set tin lids for the pots and frying pan.
1 Pancake turner, 3 by 4½ inches.
1 3-prong cooking fork.
1 Collapsible wash basin, 12 by 3 ins.‡
1 Camper's carbide lamp.
Abercrombie & Fitch Co. No. 3A937.
Be careful to read the instructions.
1 lb. Carbide for above lamp.‡
2 Canvas duffle bags, 10 by 24 inches (use for food only).‡
1 doz. Food bags, 9 by 9 inches.‡
2 Food bags, 9 by 14 inches.‡
1 Agateware milk can with tight lid—2-quart. Use for the stewed fruit only.
2 Patent egg carriers.
1 Tin bread pan, 10 by 4 inches. Use also for washing dishes.

*Pull-U-Out Sales Co., 2024 Market St., St. Louis, Mo., manufacture a device suitable for this purpose, see index.
‡Read matter under head of "The Car Kitchen" above. The Prentiss Wabers Stove Co., 34 Spring St., Grand Rapids, Mich., manufacture camp stoves. Marshall Field Co., Chicago, supply complete camping outfits.

1 Inspirator, for camp fire—(2 feet small rubber hose, one end of which is slipped over one end of a 3-inch piece of copper tubing and the other end of this tubing is flattened to make a slit about $\frac{1}{16}$ inch opening). This is a wonderfully handy thing for getting a balky fire going.

Car Equipment:

This equipment is suitable for a transcontinental trip of for a shorter one:

2 Extra tires mounted on demountable rims.
2 Extra tires with tubes, covers on them.
4 Extra tubes in bags, under rear seat.
5 Gallons good water.
*60 Feet $\frac{1}{16}$ inch flexible steel cable.
1 Medium size shovel, strapped to running board.
2 Gallons engine oil, in 1-gallon cans. Under front seat.
1 Set weed chains, heavy type.
6 Extra cross chains.
1 Set spring chain tighteners.
1 Set regular tools for car.
1 Car jack.
1 Pair good cutting plyers.
1 Piece hardwood 1½ inches by 4 feet by 10 inches.
1 2-quart canteen. Buy west of Missouri river.
1 Blow-out patch for casing.
8 Extra spark plugs.
8 Feet high-tension wire.
8 Feet low-tension wire.
1 Extra valve and spring complete.
1 Medium-sized axe. Strap to running board.
1 Small can Le Page's glue, for mending camera, etc.
1 Hose, upper radiator connection.
1 Hose, lower radiator connection.
1 Canvas folding bucket for water; 9 by 12 inches.
1 Can cup grease. Under front seat, and so packed that it cannot upset when melted.
1 Set extra electric lamp bulbs.
1 Set extra fuses for electrical system.
2 Packages small, cheap towels, for wiping machinery, etc.; one dozen in each package.
150 Feet ¼-inch best Manila rope, for packing, etc.

Personal Equipment:

When on a camping motor trip, the first thing of importance is common sense. The second is proper equipment.

Now for the list. This is the minimum for a long trip, and of course, may be added to according to the tastes and ideas of the individual, but more is entirely unnecessary and should be avoided, if possible.

1 Pair tan shoes, light-weight. Don't wear new shoes.
3 Pairs light cotton lisle socks.
1 Pair canvas puttees, light-weight. Don't wear leather.‡
2 Pairs kahki riding breeches, laced below the knee. Don't wear corduroy.‡
2 Pairs light wool drawers.
2 Light-weight wool shirts to match above.
2 Pairs B. V. D. under suits.
2 U. S. Army officers' brown shirts with patch pockets. These are twice as warm as $2.50 flannel shirts, and are practically wind-proof.‡
1 Light-weight kahki coat. To wear in towns.‡
1 Heavy mackinaw coat with shawl collar. For driving when it is cold at high altitude and by the camp fire.‡
1 Pair light-weight gauntlets, for driving.
1 Pair old street gloves, for wear around camp.
1 Kahki hat with narrow brim. Cut ½-inch ventilating holes on each side.‡
2 Blue and white bandanna handkerchiefs. Tie up snug to your neck and don't wear loose like the pictures of cowboys.
6 Pocket handkerchiefs.
1 Pair light-weight moccasins. For wear around camp and to sleep in.‡
1 Toothbrush.
1 Hair comb.
1 Pocket knife, three blades and strong.
1 Pocket compass.‡
1 Safety razor and two extra blades.
1 Can shaving powder.
1 Shaving brush.
1 Mirror, small.
1 Ingersoll watch, with fob.
1 Pair yellow goggles. Don't forget these.
1 Pair white goggles.
1 Tube tooth paste.
1 Package bachelor buttons.
1 Pair scissors, small.
1 Set needles and thread.
1 Pair manicure scissors. Don't forget these. Hangnails are a great source of trouble on long trips.
1 Narrow leather belt.
1 Stick camphor ice. Much better than any form of cold cream and very handy in package. Use it only at night unless riding in the shade of the top, as the hot sun will blister the lips on account of the beads of moisture acting as lenses on the lips after using the camphor ice.
2 Dozen cathartic tablets
1 Package gauze.
3 Rolls gauze bandages, 2 inches wide.
1 Tube vaseline, for burns, guns, etc.
2 Pairs 5-lb. wool double blankets.‡
1 Cotton quilt.
1 Tent. Trego sleeping tent. Purchase at Von Lengerke & Antoine, Chicago.
1 Camera.
12 Rolls film for camera.
1 Welcome photographic exposure record. This is a red book bought at any photo supply store.
1 Small whisk broom, for use in tent, etc.
1 Silk sleeping cap, to pull down over the ears.
2 Coarse towels.
2 Pipes, if you are a smoker, and plenty of your favorite tobacco.

What to Cook and How.

Bacon: This is the standby of all camping parties and is really the best meat to carry, as it keeps well and is easy to cook. It should be placed on bread and eaten as a sandwich, thus you will not miss butter. Fresh meat should be attempted only by the expert cook. There is a science in cooking bacon, and but few people seem to catch the idea. I will try to make it as clear as possible.

In the first place, do not buy the sliced bacon under any circumstances. Buy the bacon in the slab, as lean as possible, and of the very best quality. Buy one full slab at a time as you go along and cut this into three pieces to go into one of the larger food bags. Now, when slicing the bacon before each meal, cut the slices at least $\frac{1}{16}$ to ⅛-inch thick. Bacon which is sliced thin, cannot possibly be fried properly, as it will curl up in spite of you and burn one end while the other end is raw.

Cutting the bacon: After cutting the slices down to the rind, cut this off by passing the knife under the slices horizontally, with the slab lying flat. Lay the slices in the frying pan, putting in as many as may be required, regardless of whether they rest on top of each other or not. Set the pan on the grate and, after the grease begins to form, tilt the pan this way and that, so that the grease flows all through the slices. Watch it carefully and turn the slices frequently with your fork. In the meantime, have a plate warming on one corner of the grate, and as the slices become fairly brown on both sides, pick them out with the fork and pile them up as closely as possible on this plate. As soon as all are done, cover the plate with another and set where it will be kept warm. This will keep the slices moist with the heat and grease left in them and they will not become brittle and dry. The remaining grease in the pan can now be poured into one of the cups for future use, or that meal, for frying eggs, etc. **Eggs fried with bacon** grease have a fine flavor.

It is astonishing how few cooks know how to cook rice so that the grains will be soft and yet stand apart.

*A good auto tow line (flexible wire) is manufactured by A. Leschen & Sons Rope Co., St. Louis. It is called "Hercules Wire Rope Towing Line" and is 25 ft. long between end fittings.

‡See foot note page 517.

Boiled rice is a great dish for camp, if properly cooked, but is miserable stuff if cooked into a thick paste.

Take next to the largest pot and fill it about three-quarters full of cold water and add about one-half teaspoon of salt, then put in three-quarter cup of rice and put on the lid, placing the pot over the fire on the grate where it will get a good heat to boil. The rice should boil for about 30 minutes, and if desired, it may be tested by gathering a little in the spoon and chewing it, to see that the grains are soft. Stir frequently and scrape the bottom of the pot with the spoon.

After the rice is done, take the pot to one side of the camp and pour off all the water you can by holding the lid in place and turning the pot almost upside-down. Now set it to one side with the lid on until needed, and the rice will steam so that the grains will stand apart. You will find this a delicious dish, which should be served with evaporated milk and sugar, or with a sauce of fruit juice. Cook a fresh lot for each time served and do not try to save it for the next meal. If you have too much rice for the quantity of water it will produce a mixture like glue, and is poor stuff to eat.

Fifteen-minute bread: Most campers will shy at making bread, but really it is very simple and is made in about 15 minutes. The patent baker is a marvel and will brown the loaf equally on top and bottom, no matter how the wind blows. A special kind of fire is required to bake bread, so do not attempt it at the regular cooking fire.

***To build the correct fire,** drive two stakes in the ground about 2 inches apart and 2 feet from there drive in 2 more likewise. Between the vertical stakes, lay a wall of sticks about 1 to 1½-inch thick, perferably green sticks, and against this wall set a lot of fire stuff which will burn rapidly and make a high flame with little smoke. You must have a high flame. This should be kept going brightly until the bread is done. (See fig. 6, chart 223.)

Test the bread by piercing the loaf with a sliver of wood. If no dough sticks to the sliver, then the bread is done. Of course, it should be fairly brown on top before testing. Leave the pan in the baker and remove from the fire, setting to one side where it will receive a little heat from the regular fire to keep warm. The aluminum baker will retain the heat for quite a while.

Carry whole wheat flour only, and in the larger food bag. Of this take one and one-half cups and put it into the bread pan for mixing. Add to this one and one-half heaping teaspoonsful of baking powder, one level teaspoon of salt, three teaspoons of sugar and one and one-half cups of water. Stir gently until thoroughly mixed, but do not beat. Warm the baking pan and then grease it all over the bottom and around the sides and corners with a strip of bacon rind, then pour in the batter you have made and place the pan in the patent baker. Set this before the baking fire quite close, say one to two feet. It will begin to rise immediately and will bake into a loaf about one to one-half inches thick, which will be just right for four hungry people. This bread is great, and will stick to your ribs on the long hike. It is so much better than baker's bread and very little trouble after you once get the hang of it.

Dessert a la tour: You will find that stewed fruit is far ahead of the canned goods and much better food. In the food list you will notice that peaches, prunes and apricots are specified, dried. These will all be mixed together and used that way. The flavor is much better than when used separately.

Fill your 2-quart milk can about one-third full of this dried fruit and then fill up with cold water, adding three tablespoons of sugar the day before you start, and then at the first night stop, place the can on the grate over the fire and allow to simmer, first loosening up the lid to let the steam escape. After serving the fruit, you can put in more fruit, add more water and sugar and carry it with you to the next stop, repeating the simmering process. In this manner the mixture will become quite syrupy and of fine flavor. About every 3 days empty the can and wash out with hot water, beginning over again as you did in the first place.

The breakfast drink: Use 8 teaspoons of ground coffee to one cup of cold water in the coffee pot. Set on the fire until it comes to a boil, then pour one-half cup of cold water over the top, going round and round, and a little down the spout. Set the pot aside until served and then pour carefully and slowly, and the coffee will be clear.

No egg or anything of that sort is needed to make clear coffee. If the coffee food bag is tied tightly, it will keep in the ground state all right, so do not carry it in the can in which it is sold.

Tea: If tea is used immediately, pour boiling water over the tea leaves and let stand for a few moments only. If it stands very long with the leaves in the pot, it will make a mixture which will absolutely tan the lining of your stomach. If the tea is to be kept for any length of time, put the tea leaves in a piece of cheese cloth and tie with a bit of string, fishing this out of the pot after the tea has soaked for a moment in the boiling water. Shake out the cloth and put away for the next time. If the cloth is used, you can save the tea for a long time and serve cold, if desired. This is often handy for the late hunter in camp, if side hunting trips are made away from the car.

The army ration: Erbswurst, (pea sausage in English) powdered pea meal and bacon. This is a very palatable and nourishing food, and is used extensively as the perfect army foot by the nations of Europe. It is sold in round packages about 1 inch in diameter and 4 inches long, and each package is marked in 6 divisions, one of which is to be used for each cup of water. Boil for 20 minutes. It is already seasoned.

Pan cakes are very nice for a change and should be served with maple syrup, as one craves sweets when living out of doors. Buy the syrup in small cans. For the cakes, buy self-rising buckwheat flour and mix with cold water, with possibly an egg added for richness, until the batter is quite thin and will run readily from the spoon. Rub the frying pan with grass or a rag thoroughly to smooth its surface, then grease with a strip of bacon rind and pour in a large spoonful of batter at a time, while the pan is piping hot. The pan will hold 3 cakes of this size at a time. Cut them apart with the pancake turner as soon as you can and loosen them from the frying pan by slipping the turner under the cake without lifting it. As soon as you can handle them on the turner, flop them over to brown on the other side. If the batter is not thin enough, the cakes will be tough and heavy.

Potatoes are really a necessary article of food on a long trip lasting several weeks, and should be served about once each day, if convenient. Peel the potatoes and then boil them in the largest pot for about 20 minutes if you are going to fry them, and 40 minutes if they are to be served boiled only.

In high altitude, the boiling process will require much longer, as the water boils at lower temperature. "All that bubbles does not boil" in the high mountains.

To fry the potatoes, first boil them as above directed and then cut into slices about ¼-inch thick. Pour about $\frac{1}{16}$-inch of the bacon grease into the frying pan, covering it evenly. Heat this on the fire until it sizzles and put in the potatoes. Take a knife and immediately chop the potatoes into small pieces and put on the cover. Stir and turn over frequently with the knife and test them for softness with its point. When nice and soft they are ready to serve and the bacon grease will give them the desired browning. The bacon grease has a much better flavor than lard.

Canned Goods: These are good for a change, where they can be conveniently carried, but are not at all necessary. In all cases of vegetables and soups, simply pour the contents of the can into one of your pots and heat it over the fire. Do not forget to stir it to keep the mixture from sticking to the bottom of the pot.

*See page 519 for building a "cooking fire" and "camp fire".

Water: Be very careful of the water you drink, especially west of the Missouri river. If there is a white deposit around the edge of the lake or pond from which you wish to get the water, it is alkaline and will make you very sick. Fill your big milk can with good water in the towns and then drink that instead of taking a chance on water found by the roadside. Animals can drink alkali water without harm, whereas it would seriously affect a human being.

This 5-gallon supply of water will be used for all purposes, as it will be required only for the radiator in case of accident. Fill the radiator when you fill the gasoline tank and you will have all you need.

Cooking fire: This fire is to be built under the grate the four legs of which have been driven into the ground until the grate is about 8 inches high. Build this fire of small sticks, from the size of your finger to 1-inch diameter. No larger. Have this fire at some distance from the cars and from the main camp fire and on the lee side of both. The sticks should not be over 14 inches long. The smaller the fire, the better to keep the heat down, so that the cook is not roasted as well as the food. You may build the fire the full length of the grate if you wish, but keep it down. Do not attempt to cook at the camp fire, for the smoke and heat will make it a martyr's job. Fig. 5 shows the proper method.

A baking fire: Build this away from the other two as shown in fig. 6.

Camp fire: Do not build this near the cars and be sure to have it on the lee side of them on account of possible sparks. Build a moderate sized fire only, so that you can gather closely around it and converse easily. "Injun build little fire and sit up close—white man build big fire and sit away off." Build yours the Indian style.

Be sure to put out all fires with your shovel before breaking camp. The western forestry laws are very strict about this.

Packing: Packing the outfit on the car is quite important and it should be standarized at the start and then everything always should go back in the same place. Much time may be saved if this is carried out as all of the party become familiar with the location of each item and the car will be loaded in an astonishingly short time.

Method of stowing is as follows:

Cooking grate—Under floor mat in tonneau.

Large water can—Right running board forward.

Extra tires not on rims—Left running board forward.

2 tent beds—On end, each side of back of front seat. Tie to robe rail.

Cooking utensils—Between these beds in tonneau.

1 tent bed—Right running board. Strapped on.

1 tent bed—Left running board. Strapped on.

Shovel—Left running board behind tires.

Axe—Tonneau floor just back of beds.

Food bag—Tonneau floor. Passengers can rest feet on it.

Patent baker—Hanging where it will not be crushed.

The cooking utensils all go into a canvas bag which is sold with them and the outfit is very compact.

Food List:

2 Slabs best bacon—lean.
5 Pounds whole wheat flour.
5 Pounds sugar.
1 Pound salt.
2 Pounds best baking powder.
2 Cans maple syrup, small cans.
1 Can pepper, small.
8 Pounds ground coffee.
12 Cans evaporated milk, unsweetened.
1 Roll surgeon's plaster 1 inch wide—for sealing cans, etc.
5 Pounds dried fruit—apricots, peaches, prunes in equal portions.
1 Pound tea.
1 Can cocoa.
1 Pound self-rising buckwheat flour.
3 Pounds rice.
2 Cans tomatoes.
2 Cans corn.
2 Boxes graham crackers.
4 Quarts potatoes.
12 Packages Erbswurst.
2 Dozen eggs in patent carriers.
2 Boxes bouillon cubes.

The Official Automobile Blue Book, a Road Guide

Assists in planning a tour and gives detail running directions.

Vol. No. 1. New York and Adjacent Canada.
Vol. No. 2. New England and Maritime Provinces.
Vol. No. 3. New Jersey, Pennsylvania, Delaware, Maryland, District of Columbia and W. Virignia.
Vol. No. 4. Lower Mich., Ind., Ohio and Ky.
Vol. No. 5. Ill., So. Wis., Iowa, Mo. & W. Ky.
Vol. No. 6. The Southeastern States.
Vol. No. 7. Colo., N. Mex., Texas, Kansas, Okla., Ark., La.
Vol. No. 8. Calif., Utah, Nev., Ariz.
Vol. No. 9. Wash., Oreg., Idaho, B. C. & Alta.
Vol. No. 10. Mont., Wyo., N. & S. Dak., Nebr. and No. Col.
Vol. No. 11. Wiscn., Minn., No. Ia., No. Ill., upper Mich.
Vol. A. New York City Metropolitan Blue Book.
Vol. T. Main trunkline highways of U. S.

The price of each volume is $3.00. The address of publishers are The Automobile Blue Book Publishing Co., 243 W. 39th St., New York, 910 S. Michigan Ave., Chicago.

The Jefferson Highway is another international highway, extending from Winnipeg, Canada, to New Orleans, La. Headquarters are St. Joseph, Mo.

A very large space in which to carry needed articles on a tour is to provide a long box, width of running board and cover with black rubber carriage top cloth. This will make a good dust and rain proof receptacle in which to carry clothing, lunch boxes, etc.

INSTRUCTION No. 38.

INSURANCE, LICENSE AND LAWS: Kinds of Insurance. Automobile Registration Fees. Chauffeurs' License. Laws of Different States. Some of the Questions Asked by Some of the State Board of Examiners. SELECTING A CAR; buying a new car; judging a second-hand car; buying a commercial car.

*Insurance.

Fire insurance is very essential to the operation of an automobile, on account of the exposure it is subjected to, both on the street and in the garage, and most owners carry fire and theft policies.

Liability insurance is also a very important asset, and owners should be very careful about their selection of a company to carry their risk. The company should necessarily be one with large assets, and of sufficient financial strength to protect the policy holder through years of action in the courts, because in some cases; especially where serious injury is involved regardless of the cause or blame for the accident, years have elapsed before settlement is agreed upon, or final judgment is rendered.

Kinds of Insurance.

There are five classes of automobile insurance, as follows:

(1) Fire and theft.
(2) Liability.
(3) Property damage.
(4) Collision.
(5) Loss of use.

Fire and theft can be combined in one policy, or fire insurance can be written separate excluding theft; but the theft feature cannot be written unless accompanied by the fire insurance. Collision can also be included in the fire only, or the fire and theft policy, but it like the theft insurance cannot be written separately. Liability and property damage is usually written in a separate policy, although several companies are writing a joint "all risks" policy covering fire, theft, liability, property damage and collision. This can be done by re-insurance between the liability and the fire companies.

(1) The standard automobile fire and theft policy covers the body, machinery and equipment of the car. Extra bodies, robes, automobile coats, hats, caps, gloves, leggings, boots, goggles and chauffeur's livery are not included unless provided for under a separate endorsement, for which additional premium is charged in accordance with the amount of coverage desired. Automobile fire insurance is written in two forms; one covers fire and theft, and is known as a "valued policy" on account of the company being liable for the amount stated in the policy at the time of a loss; the other provides that the company may deduct a reasonable amount from the loss for depreciation however caused. A credit in the rate is given for the latter form of coverage which is known as the "non-valued form." A credit of 15 per cent is granted from the fire rate where an approved chemical fire extinguisher is attached to the automobile.

Theft insurance as stated above can only be written in connection with a fire policy, and the same conditions regarding "valued" and "non-valued" clauses apply. On all cars listing under $2000.00 the companies require the attachment of an approved locking device for which a credit of 15% is granted from the theft rate. Where no lock is provided an additional charge of $15.00 is made.

(2) Liability insurance provides protection against accidents to the public resulting in injury or death. The usual limits of liability are $5,000.00 for an accident resulting in an injury to one person and $10,000 for an accident resulting in injury to more than one person. The purpose of this insurance is to pay judgments, costs of court, attorney fees, witness fees, investigation and settlement costs, and other expense necessary to the protection of the automobilist, not exceeding however, the limits above stated. These limits may be increased where necessary by payment of additional premium.

(3) Property damage insurance covers damage to the property of others, not exceeding one thousand dollars.

(4) Collision Insurance covers loss or damage to your car caused by a collision with another object. There are three classes of collision insurance; one known as the ($50.00 deductable form), provides that the company will deduct $50.00 from each claim; another known as the ($100.00 deductable form), provides that the company will deduct $100.00 from each claim, and still another known as the (full coverage form), which provides that the company will pay all claims in any amount. The insurable value on collision insurance is based upon the same principle as fire insurance, a fixed percentage of the list price of the car being granted in accordance with the age, use, physical condition, etc.

(5) Loss of use: This form of coverage has just recently been included, and applies in connection with the property damage insurance, providing reimbursement to the owner on account of sums he may be called upon to pay to others through the loss of the vehicle which has been damaged; i. e.: cost of rental of another vehicle pending repairs to the one damaged, not exceeding one thousand dollars.

Rates.

Insurance rates vary in different parts of the country, therefore it is advisable to see your local insurance agent.

* AUTOMOBILE LICENSE OF DIFFERENT STATES; the cost and how to secure a license.

There are two kinds of license issued for automobiles; one to the owner of the car which covers a tax or fee on a car as well as the privilege of the owner to drive the car. The other, is a license issued to a professional chauffeur.

Some states do not require chauffeurs' license. Other states require the chauffeur to obtain a license which is usually done by writing to the secretary of the state at the capitol city for a form to fill out, which, when filled in and the amount of license remitted, he is then supplied with a badge and receipt. Other states require an examination. The table below gives the name of the states requiring the above and where to send for the license.

The information, even though you do not purchase a license can be obtained by writing to the secretary of your state. Inasmuch as the laws are sometimes amended or changed, it would be well for the reader to write for the information, which will be supplied to him gratis.

The age of driver of an automobile must not be less than 18 years, in all states except California (16), Colorado (15), Nebraska (16), New Hampshire (16), New Mexico (14), New Jersey (16), Ohio (16), Pennsylvania (16), Rhode Island (16), Wyoming (15), Delaware (16). Some of the other states do not set an age limit.

State.	Registration.				Licenses.				Non-Resid'ts.	Speed Regulation.
	Where to Apply.	Fees.	Duration.	Renewal.	Requirements.	Fees.	Duration.	Renewal.		
ALABAMA	Sec. of State. Montgomery	Less than 20 h. p., $7.50; under 30, $12.50; under 40, $17.50; 40 h. p. or more, $30; trade, $100 per garage, dealers, $125; rented cars, $25.	Annual	October 1st.	No examination.	Chauffeur's licence, $5, original; $2.50, renewal.	Annual.	Oct. 1st.	Exempt (reciprocity).	Prima facie evidence of excess; 30 miles per hour ¼ of a mile.
ARIZONA	Sec. of State, Phoenix.	25 h. p. and less, $5; 25-40, $10; over 40, $15; manufacturers and dealers, one registration; 50c. for each additional seal.	Annual	January 1st.	None.	Chauffeur's license, $5.	Perpetual.	None.	Exempt, 6 months.	Closely built up, 10 m.; elsewhere in city or town, 15 m.; open country, 20 m.
ARKANSAS	Sheriff of County.	$10. Manufacturers and dealers one $10 license for each class of car.	Annual	January 1st.	No examination.	Chauffeur's license only, $1.	Annual from date of filing.	——	Exempt.	Prima facie evidence excess; cities, towns, 15 m. for ½ m.; open country, 20 m. for ¼ m.
CALIFORNIA	Motor Vehicle Division, Sacramento.	$2.00. Manufacturers and dealers, $2.00 for each class of machine; 50c. for each additional tag.	Annual	January 1st.	No examination.	Chauffeur's license only, $2.	Annual from date of issue.	Expiration.	Exempt 3 months in calendar year.	Cities, 15 m.; open country, 20 m.
COLORADO	Sec. of State, Denver	Up to 20 h. p., $2.50; 21-40, $5, 41 up, $10. Trade, $5, five cars.	Annual	January 1st.	No examination.	Chauffeurs, $1.	Annual.	Jan. 1st.	Exempt 90 days.	No general speed limits.
CONNECTICUT	Sec. of State Hartford.	50c. per h. p. Manufacturers, $1.00 each, not less than 25 machine. Dealers, $50.00.	Annual	January 1st.	No examination.	All operators, $2.	Annual.	Mar. 1st.	Exempt.	Prima facie evidence of excess; 25 m. for ¼ m.
DELAWARE	Sec. of State, Dover.	$5. Trade, $5.00 each car with same number	Annual	January 1st.	No examination.	All operators, $5; family $8.	Annual.	Jan. 1st.	Exempt (reciprocity).	Cities and towns, 12 m.; open country, 20 m.
DISTRICT OF COLUMBIA	Automobile Board, Washington.	$2. Fees paid to Collector of Taxes, Washington.	Perpetual.	——	Examination. Operator's permit.	All operators, $2.	Perpetual for one car and owner.	——	Exempt (reciprocity).	Maximum, 20 m.;
FLORIDA	Tax Collector of County.	Less than 10 h. p., $3; 11-20 h. p., $6; 20-40, $10; 41-50, h. p., $15; 51-60, $20; 61-70, $30; over 70, $50.	Annual	October 1st.	No examination.	Chauffeurs, $2.	——	——	Exempt, 15 days.	No general speed limits.
GEORGIA	Sec. of State, Atlanta.	$5.00.	Annual	March 1st.	None.	None.	——	——	Exempt, 30 days.	
IDAHO	Sec. Highway Commission, Boise.	20 h. p. or less, $15; 20-40, $20; 41-50, $25; over 50, $40.	Annual	January 1st.	No examination.	——	——	——	Exempt (reciprocity).	Prima facie evidence of excess; 20 m. per hour for ¼ mile.
ILLINOIS	Sec. of State, Springfield.	25 h. p. or less, $4; 26-35 h. p., $6; 36-50 h. p., $8, over 50 h. p., $10; electrics, $6; trade, $15.	Annual	January 1st.	Owner's sworn application. Chauffeur's examination.	Chauffeurs only: $5, original, $3, renewal.	Annual.	Jan. 1st.	Exempt, 60 days.	Prima facie evidence of excess; cities, 20 m.; open country, 25 m.

*See page 857 relative to Ill. light law. In some of the states these laws may have been changed. See page 435 for requirement of light lens. Above prepared some time ago. Write to Secretary of State for latest revised laws.

INDIANA	Sec. of State, Indianapolis.	Up to 25 h. p., $6; 25-40, $8; 40-50, $15; over 50, $20. Elec., $3, commercial, $6. Trade, $25, dup. plates, $1.	Annual	January 1st.	Examination, chauffeurs only.	$2.00	Annual.	Jan. 1st	Exempt, 60 days.	Business portion, city or town, 10 m.; residence, 15 or 20 m.; open country, 25 m.
IOWA	Sec. of State, Des Moines.	20 h. p. or less, $8; over 20, 40 cents per h. p.; electric or steam, $15; trade, $15; each set of dup. tags, $1.	Annual	January 1st	None.	—	—	—	Exempt (reciprocity).	Presumptive evidence of excess; over 25 m.
KANSAS	County Treasurer.	$5. Trade: register one car of each class.	Annual	July 1st,	No examination.	—	—	—	Exempt, 30 days.	Cities or towns, 12 m.; open country, 25 m.
KENTUCKY	Sec. of State, Frankfort.	Less than 25 h. p., $6; less than 50 h. p., $11; 50 h. p. and over, $20. Trade: one registration in each class.	Annual	January 1st.	No examination; no license.	—	—	—	Exempt (reciprocity).	Prima facie evidence of excess; cities, 10 and 15 m. for ¼ m.; open country, 20 m. for ¼ m.
MAINE	Sec. of State, Augusta.	20 h. p. and under, $5; 21-35 h. p., $10; over 35 h. p., $15. Trade: $25, registering all vehicles.	Annual	January 1st.	Examination optional with Sec. of State.	All operators, $2.	Annual.	Jan. 1st.	Exempt, 20 days.	Cities and towns, 10 m.; open country, 25 m.
MARYLAND	Com. of Motor Vehicles, Baltimore.	10 h. p., $5; 20 h. p., $10; 30 h. p., $15; 40 h. p., $20; over 40, $25. Trade: $6 per car or flat sum $100.	Annual	January 1st.	Examination optional with Commissioner.	Owners, $2 perpetual, chauffeurs, $6.	Annual.	Y- from date.	Exempt, 2 periods of 7 days reciprocity.	Prima facie evidence of excess; cities, 18 m.; open country, 25 m.
MASSACHUSETTS	State Highway Commission, Boston.	Under 20 h. p., $5; 20-29 h. p., $10; 30-39 h. p., $15; 40-50 h.p., $20; 50 h.p. up, $25. Trade: $5 car.	Annual	January 1st.	Examination for chauffeurs.	All operators; original, $2; renewal, 50c; exam., $2.	Annual.	On date of issue.	Exempt (reciprocity), (3).	Prima facie evidence excess: open country, 20 m. for ¼ m.; cities, towns, 15 m. for ¼ m. or more than 8 m. where view is obscured.
MICHIGAN	Sec. of State, Lansing.	$3. Manufacturers and dealers, $10; $2 duplicate sets of plates.	Annual	January 1st.	No examination.	Chauffeurs, $2.	Annual.	Jan. 1st.	Exempt (reciprocity).	Business portions, 10 m.; elsewhere, cities and towns, 15 m.; open country, 25 m.
MINNESOTA	Sec. of State, St. Paul.	$1.50. Trade: $10.00, with $1.00 for each set of duplicate tags	Triennial.	January 1st.	Examination.	Chauffeurs, $3 first year; $2 annually thereafter.	—	Jan. 1st.	Exempt, 30 days.	Prima facie evidence of excess; cities, 15 m. for ¼ m.; open country, 25 m. for ¼ m.
MISSISSIPPI	State Auditor, Jackson.	$2 per vehicle perpetual and 30c. per h. p. annual.	Perpetual.	June 1st.	—	—	—	—	Exempt, 60 days.	—
MISSOURI	Sec. of State, Jefferson City	Up to 12 h. p., $2; 12-23 h. p., $3; 24-35, $5; 36-47, $7; 48-59, $8; 60-71, $10; 72 h. p. up, $12. Trade: $10	Annual	February 1st.	No examination.	Chauffeur's license only, $1.50.	Annual.	Feb. 1st.	Exempt, 20 days.	Over 25 m. for ¼ m. presumptive evidence of excess
MONTANA	Secretary of State, Helena.	Trade, $10, for each type, $2.	Perpetual.	January 1st.	No examination.	Chauffeur's license, $2.	Perpetual.		Exempt.	Reasonable and proper.
NEBRASKA	Sec. of State, Lincoln	$2.00. Trade: register one vehicle of each class.	1 year from issue.	—	No license.	—	—	—	Exempt 30 days at a time.	Cities and towns, 12 m.; open country, 25 m.
NEVADA	Secretary of State, Carson City	12½ cents per h. p.; $2.50 minimum. Trade: registers one vehicle of each type, dup. plates, $1.	Annual	January 1st.	No examination.	No fees.			Exempt 30 days.	Reasonable and proper.
NEW HAMPSHIRE	Sec. of State, Concord	Up to 15 h. p., $10; 16-20, $15; 21-40, $20; 41-50, $25; 51-60, $30; over 60, $40 Trade: $25.	Annual	January 1st	Examination.	All operators; see (4) below.	Annual.	Jan. 1st.	Exempt ten days. (3).	Conclusive evidence excess: city or town, 15 m. for ¼ m.; open country, 25 m. for ¼ m.
NEW JERSEY	Com. of Motor Vehicles, Trenton, N. J.	10 h. p. or less, $4.50; 11-29 h. p., $7.50; 30 h. p. or more, $15. Trade: one number for 5 cars, $5 per car.	Annual	January 1st.	Examination. All new operators.	Less than 30 h. p., $2; 30 h. p. and over, $4.	Annual.	Jan. 1st.	Reciprocity, 15 days.	Cities, 12 m.; open country, 25 m.
NEW MEXICO	Sec. of State, Santa Fe	Less than 12 h. p., $2; 12-19, $4; 20-29, $6; 30-39, $8; 40-49, $10; 50 or more, $12. Dealers, $12	Annual	January 1st.	None.	—	—	—	Exempt, 60 days.	No general speed limits.
NEW YORK	Sec. of State, Albany, New York & Buffalo	25 h. p. or less, $5; 25-34, $10; 35-49, $15; 50 h. p. up, $25. Trade: $15. $1 for each duplicate tag.	Annual	February 1st.	Examination. Chauffeurs only.	$2 for examination; $3 license fee; renewal, $2.	Annual.	Feb. 1st.	Exempt (reciprocity).	Presumptive evidence of excess; 30 m. for ¼ mile.
NORTH CAROLINA	Sec. of State, Raleigh.	Up to 25 h. p., $5; 25 to 40 h. p., $7.50; over 40 h. p., $10. Trade, $10; duplicate plates, $1.	Annual	July 1st.	None.	—	—	—	Exempt, 15 days.	Business portion, city or town, 10 m.; residence, 15 m.; open country, 25 m.
NORTH DAKOTA	Sec. of State, Bismarck.	$3.00.	Annual	January 1st.	None.	—	—	—	Exempt.	Cities and towns, 10 m.; open highway, 20 m.
OHIO	Sec. of State, Columbus.	Gasoline and steam vehicles, $5; electric, $3. Trade: $20 for each make (motive power) of machine.	Annual	January 1st.	Chauffeur's examination only.	Chauffeur's license only, $3.	Annual.	Jan. 1st.	Exempt.	Closely built up, 8 m.; cities, 15 m.; open country, 20 m.
OKLAHOMA	Highway Commissioner, Oklahoma City.	$1.00	Annual	January 1st.	No examination.	No fees.	—	—	Not exempt.	No speed limits.
OREGON	Sec. of State, Salem.	Electric vehicle, $3 and $5; others: 26 h. p., $3; 27-36, $5; 37-40, $7.50, above 40 h. p., $10. Dealers, $10.	Annual	January 1st.	No examination.	Chauffeur's license only, $2 (5).	Annual.	Jan. 1st.	Exempt, 30 days.	25 m.
PENNSYLVANIA	State Highway Dept., Harrisburg	Up to 20 h. p., $5; 20-35 h. p., $10; 35-50 h. p., $15; 50 h. p. up, $20. Trade: $10 per car, 10 cars per application, half fees after July 1. Solid tires by weight.	Annual	January 1st.	No examination; see (6) below.	Chauffeur's license only, $2.	Annual.	Jan. 1st.	Exempt (reciprocity).	24 m.
RHODE ISLAND	State B'd Pub. Rds., Providence	20 h. p. or less, $5, over 20 h. p., $10, over 30 h. p., $15; over 40 h. p., $25; trucks, $7. Trade: $50.	Annual, from date of issue.	—	Must show knowledge.	All operators, $2.	Annual from date of issue.	—	Exempt, 10 days.	Cities and towns, 15 m.; open country, 25 m.
SOUTH CAROLINA	Clerk County Court.	$1.00	—	—	None.	—	—	—	Not exempt.	15 m.
SOUTH DAKOTA	County Treasurer.	$6.00. Trade: $10. $2 per set dup. plates.	Annual	January 1st.	None.	—	—	—	Exempt (reciprocity).	25 m. presumptive excess.
TENNESSEE	Sec. of State, Nashville.	Secretary of State, $2. County Clerk, $1.	Perpetual.	—	None.	—	—	—	Not exempt.	20 m.
TEXAS	County Clerk.	0.50.	—	—	None.	—	—	—	Not exempt.	City or town, 8 m.; open country, 18 m.
UTAH	Sec. of State, Salt Lake City.	$2. Manufacturers and dealers, $2 for each style of machine.	Perpetual.		No examination.	Chauffeur's license only, $2.	Perpetual.	—	Exempt.	Closely built up, 10 m.; elsewhere, city or town, 15 m.; open country, 20 m.
VERMONT	Sec. of State, Montpelier.	First year, $1 per h. p., second year, 75% of first; third year on, 50% of first registration. Trade: $25.	Annual	January 1st.	Examination discretionary with Sec.	All operators, $2.	Annual from date of issue.	—	Exempt (reciprocity), see (7) below.	Prima facie evidence of excess; city or town, over 10 m.; open country over 25 m.
VIRGINIA	Sec. of Commonwealth, Richmond.	30 h. p. or less, $5; over 20 h. p. and under 45 h. p., $10; 45 h. p. and over, $20. Trade: $50.	Annual	January 1st.	No examination.	Chauffeur's only, $2.50.	Annual.	Jan. 1st.	Exempt 2 periods of 7 consecutive days.	Cities, 8 m.; open country, 20 m.
WASHINGTON	Sec. of State, Olympia.	$2.00.	Annual	June 1st.	None.	—	—	—	Exempt.	Business portion of city or town, 12 m.; open country, 24 m.
WEST VIRGINIA	State Aud., Charleston.	$10.00.	Annual	July 1st.	No examination.	Chauffeur's license only, $2.	Perpetual.	—	Exempt (reciprocity).	Cities, 15 m.; open country, 20 m.
WISCONSIN	Sec. of State, Madison.	$5. Trade: $10 for each garage with 6 number tags; additional tags, 50 cents each.	Annual	January 1st.	None.	—	—	—	Exempt.	Cities and towns, 15 m.; open country, 25 m.

Note. Above prepared sometime ago—see foot note, page 522.

ADMISSION OF CARS INTO CANADA.

The customs regulations governing the temporary admission of motor cars into Canada, as contained in memorandum No. 1571B, in force April 1, 1910, and reprinted below, require generally a bond for double the estimated duties and a deposit of $25. For motor cars remaining in Canada not more than three days, a permit is issued, apparently without deposit or bond.

1. Motor cars manufactured abroad and not duty paid, when imported into Canada by the owners personally who are non-residents of Canada or temporary visitors therein, may be admitted under bond or upon cash deposit, for owners for touring purposes only, provided the owner is in nowise connected with any motor car business and that the machine is not to be used for any commercial or business pursuits whatever while in Canada, and subject to the following regulations and conditions:

(a) The motor car shall be reported on form approved (E29½) in duplicate, at the customhouse at the port of importation, where a careful examination and appraisement shall be made.

(b) As invoice showing the selling price of the motor car shall be produced when practicable, as an aid to the collector in determining the value.

(c) Upon receiving a deposit of $25 and a bond executed in Canada in approved form for double the estimated duties, conditional for th' due exporation of the motor car covered thereby within three months from date of bond, the collector may grant a permit accordingly, to be in dorsed on the duplicate report, for the use of the motor car in Canada for touring purposes.

(d) The bond shall be signed by the importer and by two residents; or by the importer and by a resident of Canada who has deposited with the collector of the port of entry, the general guaranty of an incorporated guaranty company, authorized to do business in Canada, and which guaranty is then available as a security in the case; provided, that the special bond of an incorporated guaranty company authorized to do business in Canada, may also be accepted, in approved form, instead of the bond first herein mentioned, and that the cash deposit of $25 may be dispensed with in any case covered by a special or general guaranty bond.

(e) The bond shall be filed by the collector with the tourist's report attached, and the duplicate report shall be handed to the tourist with permit and receipt for deposit indorsed thereon.

(f) The deposit shall be subject to refund by the collector upon return of permit, with proof of the exportation of the motor car within three months from date of bond. In default of the exportation of the motor car with proof of such exportation, to the satisfaction of the collector within three months from the date of importation, the deposit is to be entered as customs duty, and the provisions of the bond enforced.

(g) The term "motor car" herein is to be held as including the outfit accompanying the motor car.

2. Motor cars manufactured abroad and not duty paid, may not be reimported for touring purposes within six months from the time of their exportation after previous entry in bond for touring purposes. This limitation, however. shall not apply to motor cars provided for in the section next following:

4. The regulations in memorandum 940B, of July 31, 1897, concerning teams and carriages crossing the frontier, provide that where the persons in charge of such teams and carriages are well known to the customs officer, he may allow the outfit to cross the frontier and return within one week, subject only to the usual report, search and examination. This provision may be extended to tourists' motor cars when the customs officer is satisfied that the motor cars will be used only within the limits of the port of importation, and vicinity in conformity with customs, laws and regulations.

British Columbia.

Write The Western Canadian Motorist, Fourth Floor, World Bldg., Vancouver B. C. for copy of the laws. The registrations are made with the superintendent of Provincial Police.

Vancouver, B. C. have a street traffic by-laws. issued by the city of Vancouver.

Quebec.

Quebec Moto-Vehicle Laws can be obtained from The Provincial Treasurer, or Mr. C. F. Dawson, Collector of Inland Revenue; City Hall. Montreal, Quebec.

Canal Zone.

Write to Colonel Chester Hardy, Governor—for information.

CHAUFFEURS' EXAMINATION QUESTIONS.

The questions below are not a standard set but merely gives an idea as to the questions sometimes asked the applicant for chauffeur's license, in those states requiring examination. In some states the applicant must also show his ability to drive a car.

Q. 1.—What vehicles usually have the right of way in large cities?

A.—Fire department, ambulance, mail wagons and heavily loaded trucks, police and emergency wagons.

Q. 2.—What do you do when running parallel to a street car and the latter stops to allow passengers to alight?

A.—Slow up, stop, or pass 8 feet away.

Q. 3.—What would you do if your car caught fire?

A.—Turn off gas at supply pipe, smother flames with coat, blanket or sand (do not use water) and get a fire extinguisher into action as quickly as possible.

Q. 4.—Of what use is the carburetor to a gasoline engine?

A.—It mixes air with the gasoline in proper proportion.

Q. 5.—How can you detect when your engine is losing compression?

A.—By loss of power when running, or by cranking slowly to test each cylinder, or by a hissing noise on compression stroke.

Q. 6.—What would you do when climbing a hill and your brakes refused to hold and your gear refused to mesh?

A.—Back car crossway of road.

Q. 7—What would you do if ascending a hill at a high rate of speed and a car crossed your path from a crossroad?

A.—Blow horn and slow up, or stop or turn car in same direction as other car is running.

Q. 8.—How would you ascertain the amount of gasoline in your tank at night?

A.—Measure it with a stick or rule, being careful to keep any flame away from opening of tank.

Q. 9.—What offense would justify a magistrate to revoke your license?

A.—Driving while intoxicated or trying to escape after an accident on the highway.

Q. 10.—How can you tell when your differential is out of order?

A.—By unusual noises or if both rear wheels do not run evenly after ascertaining that the brakes do not need adjusting.

Q. 11.—What precautions do you take in driving on a dark or rainy day?

A.—Put on skid chains drive slowly and carefully.

Q. 12.—What action would you take if you injured any person on a highway?

A.—Stop and render any assistance possible. notify an officer.

Q. 13.—What are several causes of your engine overheating?

A.—Lack of water, no oil, running on too rich a mixture or too far retarded spark, loose or broken fan belt.

Q. 14.—What are the road and street speed laws of most cities?

A.—Not allowing to run over 30 miles an hour, and 4, 6 or 8 in the city; use judgment.

Q. 15.—What are the causes of the rear tires wearing unevenly?

A.—Wheels out of alignment, brakes out of adjustment.

Q. 16.—How would you start the car if unable to turn the crank?
A.—Jack up the rear wheel, putting speed lever into high gear. After starting the engine, put the lever in neutral.

Q. 17.—What would you do if your engine stalled in the middle of a R. R. track?
A.—Flag a train that may be approaching or push car off track, put speed lever in neutral and start engine as quickly as possible.

Q. 18.—What is the cause of light smoke issuing from the exhaust pipe?
A.—Too much oil in crank case or too much gasoline.

Q. 19.—In what position would you leave your car at the curb?
A.—As near the curb as possible, right side on.

Q. 20.—What precaution would you observe in driving near a fire hydrant and discharging passengers from your car?
A.—Stop at least ten feet from the hydrant. (varies from 6 to 20 feet.)

Q. 21.—What is your spark lever for?
A.—For controlling the timer or breaker on the magneto.

Q. 22.—What is your gas lever for?
A.—For controlling the amount of fuel for the engine.

Q. 23.—What is your accelerator for?
A.—A foot control for the throttle.

Q. 24.—What is the clutch on your car for?
A.—For engaging or disengaging the engine from the driving wheels.

Q. 25.—What is the difference between a contracting and an expanding band brake?
A.—An expanding brake expands on the inside of the brake drum, while a contracting brake tightens around the outside of the drum.

Q. 26.—What equipments are required by law on motor vehicles?
A.—License number plates on front and rear of machine, 2 side lamps, 1 tail lamp and horn or other signaling device.

Q. 27.—What should be the position of the speed lever in starting an engine?
A.—In the neutral position.

Q.28.—How many kinds of brakes are there on automobiles?
A.—Two; running or foot brake and emergency or hand brake.

Q. 31.—What is an inlet chamber?
A.—A part of the cylinder which encloses the inlet valve.

Q. 32.—What is an inlet valve?
A.—The valve which opens during the suction stroke of the piston, allowing the mixture or gas to enter the cylinder.

Q. 33.—If when traveling on the public highway you discovered some fault with your steering device, what would you do?
A.—Stop at once and fix it.

Q. 34.—How can you tell the difference between a high and a low tension magneto?
A.—By looking at it. A high tension magneto is used in the jump spark system without the use of a separate coil or transformer, if there was a separate coil I would know it was a low tension magneto.

Q. 35.—What system of ignition has a low tension magneto.
A.—Make and break or magnetic plugs or with a separate high tension coil.

Q. 36.—What system of ignition has a high tension magneto?
A.—Jump spark system.

Q. 37.—If engine could not pull the car up a hill on high speed, what would you do?
A.—Change into next lower gear.

Q. 38.—If engine was not powerful enough to pull the car up a hill on first or low speed, what speed would you use?
A.—Turn the car around and go up on reverse.

Q. 39.—How would you separate water, gasoline and other foreign substances?
A.—Strain through chamois or fine wire gauze.

Q. 40.—Name several conditions which will cause an engine to knock or pound?
A.—Loose bearings, feeding too much gas, or running on too far advanced spark, and preignition from carbonized cylinders.

Q. 41.—Name all parts of an automobile that should be lubricated and state whether oil or grease should be used?
A.—Oil in lubricator for main bearings, connecting rods and piston; heavy oil or grease in transmission, differential, steering gear, universal joints and hub caps.

Q. 42.—If driving on a road and you should wish to pass a vehicle moving in the same direction, directly in front of you, which side of the vehicle would you pass, right or left?
A.—Left side.

Q. 43.—What will cause a back fire in the carburetor?
A.—Broken, sticking or leaky inlet valve.

Q. 44.—What is meant by one blast of a traffic police whistle at a street crossing?
A.—Proceed east and west traffic (varies).

Q. 45.—What will cause a back fire in the muffler?
A.—Engine missing fire or too rich a mixture.

Q. 46.—John Smith, a duly licensed chauffeur, operates a motor vehicle under the new law, and accompanied by a friend. May the friend drive the car?
A.—No, not unless John Smith retains complete control of the car.

Q. 47.—What are you required to do when a horse or other animal on the highway appears frightened?
A.—Slow up or stop, if necessary. On a narrow country road it may be necessary to stop the engine.

Q. 48.—If you wish to stop your car and your foot brake does not hold, what would you do?
A.—Use the emergency or hand brake.

Q. 49.—How often is it necessary to examine your brakes?
A.—Every day you get out.

Q. 50.—In the event of a vehicle coming towards you on the highway, what precautions would you take?
A.—Keep to the right; blow horn, if necessary.

Q. 51.—What are the controlling parts of an engine?
A.—Spark and gas levers, clutch, brake, speed-lever and the steering wheel.

Q. 52.—How would you control your car going down a steep incline?
A.—Retard spark and gas, put machine in low gear, switch off ignition, and, if necessary, also use hand brake.

Q. 53.—What would you do if a car while proceeding in front of you suddenly swung around in your course?
A.—Slow up or stop, blow horn, hold out hand or operate signal light as warning to anyone in rear.

Q. 54.—What is the speed limit in crowded city streets?
A.—Four to six miles per hour.

Q. 55.—What penalty is there, according to law, for any person driving a car while in an intoxicated condition?
A.—Felony; revoke license perhaps.

Q. 56.—What position should the controlling parts of engine be in starting?
A.—Speed lever in neutral, emergency brake on, spark retarded and gas lever slightly advanced.

Q. 57.—Why is the spark lever advanced after starting the engine?
A.—To make the spark take place sooner in relation to the position of the piston in the cylinder; that is instead of the spark taking place just over high center, it will then occur on the high center, or just before when running fast.

Q 58.—What effect will too far advanced spark have on the engine?
A.—It will cause a metallic knock in the cylinder and might break a connecting rod or cause engine to overheat.

Q. 59.—What is the timer or commutator for?
A.—For timing the spark.

Q. 60.—Should you be going south on a busy street and you wished to turn west, how would you turn.
A.—Slow down to four miles an hour, hold out hand as signal for vehicles in rear and turn west, keeping northwest of center crossing.

Q. 61.—Should you be going north and you wished to turn west, how would you turn?
A.—Slow down to four miles per hour, hold out hand as signal for vehicles in rear, and turn west, keeping northeast of center of crossing.

Q. 62.—What would be the penalty in taking a car without permission of the owner or authorized agent of same?
A.—Felony; revoke license, perhaps.

Q. 63—What signal would the driver of a horse vehicle give you should he want you to stop?
A.—Hold up his hand or whip or perhaps shout.

Q. 64.—What precautions would you take before crossing a railroad track?
A.—Watch for an approaching train; drive carefully.

Q. 66.—How would you time a car with magneto ignition and how would you time it with battery ignition?
A.—With battery ignition the spark occurs about 1/16 of an inch over high center of compression; with magneto the spark is set to occur on high center.

Q. 67.—What is the float in the float chamber for?
A.—To regulate the level of the gasoline.

Q. 68.—Draw a diagram of the manner in which you would make a turn in a busy street intersection.
A.—.......... . ...

Q.69.—Where is the differential on a shaft driven car, and where is it on a double chain driven car?
A.—In shaft driven cars on the rear construction, in double chain driven cars, on the jack shaft.

Q. 70.—What would you do if you saw an automobile or any other vehicle trying to escape from justice after injuring a person on the public highway?
A.—Take his number and render any assistance I could to apprehend the offender.

Q. 71.—What is the penalty for a person trying to escape after such an accident; what is the nature of the crime he is committing?
A.—Felony; his license could be revoked.

Q. 73.—What signal would you give cars behind you, if going to make a turn? if stopping?
A.—Hold your hand out to the side of car.

Q. 74.—What will cause the cylinders to carbonize?
A.—Too rich a mixture or too much oil being used in lubrication.

Q. 75.—What is meant by three blasts of a police whistle?
A.—An alarm signal; all vehicles pull as close to the curb as quick as possible and stop. (Not in all cities.)

Q. 76.—What would you do should you be going along a country road at the rate of 35 miles per hour and a car should cross your path suddenly?
A.—The law is 30 miles per hour, and you should not be driving 35. Blow horn and stop or turn in same direction other car is going.

Q. 77.—What precautions should be taken before taking out a car?
A.—See that there is water in the radiator, gasoline in the tank, oil in the lubricating system, tires properly inflated, lamps (2 side and 1 tail) filled, battery charged horn, and license plates in place.

Q. 78.—Can the ordinary car run without a differential?
A.—No, not around corners without injury or wear to tires.

Q. 79.—How early and how late would you light your lamps?
A.—Light them one-half hour after sunset and put them out one-half hour before sunrise, or be governed by weather conditions.

Q. 80.—How many kinds of transmissions are there in general use today?
A.—Three; sliding gear, planetary, and friction disk.

Q. 81.—What is meant by timing your engine?
A.—Setting the valves so that the inlet opens and the exhaust closes, according to marks on fly wheel, and setting clearance of valves.

Q. 83.—My engine was running on magneto; on throwing off the switch the engine continued to run; the switch was found O. K. What was the trouble?
A.—Magneto ground wire was broken and the break was hidden by the insulation.

Q. 84.—If while running close behind another car, the said car should turn suddenly, what would you do?
A.—Swing with the other car, or in the same direction.

Pointers on Selecting a New Car.

Power. This is determined by the number of passengers to be carried and the condition of the roads. If the country is a flat district, a low powered car will do efficiently and infinitely more economically what in a hilly country would necessitate perhaps nearly twice the power to do work on high gear. For hilly country a car with a low reduction to rear axle should be selected in order that the engine take the hills on high gear.

Body. This is not much a matter of choice nowdays, as the cars are all built in large quantities and to a standard type. Putting aside for the moment the case of those who from consideration of price alone would confine themselves to a car of power and size suited for a two-seated body only, it is best to have a "touring car" body of 5 passenger type. Though the back seats may be used only once in a while, they are nevertheless too often wanted if not there, and the advantages of being able to give friends a lift and of having plenty of room for luggage and parcels are well worth the slight difference.

Enclosed bodies: The touring car body is equipped with a very serviceable top and in combination with a glass front or wind shield and suitable side curtains, this type of body can be converted into a fairly weatherproof vehicle.

The coupe and cabriolet body, page 16 is a very popular type for business purposes as it protects one from the dust and weather and is a very comfortable type of body for winter use.

The sedan type of body is a very popular type of body for family use and can be fully enclosed for winter and opened for summer use. This type of body is adapted for those who drive their own car.

The limousine is a more elaborate type of body and is used where a chauffeur is employed, as the drivers seat is separate from the other seats.

The price with many fixes itself; that is to say, their means enable them to decide in a very short time how far they can go. In any event, to arrive at a maximum figure one must include in the calculation a sum no less than, say, $75.00 to $100.00 for a small car and so on in proportion to the size, in addition to the purchase price, in acquiring those accessories, spare tires and tubes, which are necessary. See "Specifications of Leading Cars" for prices.

Service: When purchasing a car don't forget that in time you will need parts and your car will require expert attention. Investigate this feature and find out if the agent carries parts in stock and if he gives his other customers satisfactory service and if he is reasonable in price.

Constant attention is necessary. Whether you intend to employ a chauffeur or look after the car yourself is another point to consider. There is a limit to the size of car which the owner can (if in pretty constant use), attend to himself, unless he be a man of great leisure, and moreover keen enough to put up with the drudgery involved. It is useless to conceal the fact that a car will require constant attention and while a man may find the time to do justice to a moderate-sized car, a large car might be too much for him.

Cost of running—or up-keep. Here lies the crux of the whole matter. Closely allied with the important question of original outlay is that of the running cost, which must be taken into consideration to a certain extent, when buying. The size of the bill for up-keep bears, of course, a direct proportion to the mileage run. As regards the fuel consumption, this item will not be a large one in any car up to, say 25 horsepower, unless there is some radical defect in the system, or temporary want of adjustment. In large and heavy cars the gasoline bill quickly mounts up.

***Tires is the largest item in the cost of up-keep** and this charge becomes heavier as the speed increases and is again directly proportionate to the mileage run.

There are two kinds of pneumatic tires in general use, the "fabric" tire and the "cord" tire, as explained on pages 564, 559 and 566. The "cord" type is the best. The intial cost may be greater but there is a saving in the long run.

The non-skid tire should be selected for rear wheels. This extra cost is well worth the difference as the extra wear from the extra amount of rubber, to say nothing of the non-skid feature is worth the difference.

Small light tires spell constant trouble, not to mention short life. Be sure the car is equipped with tires of **ample size** to sustain the weight and speed, also **determine if the size of tire is a standard size** and if it can be obtained readily. Many of the former sizes have been discontinued —see page 555. Also determine if the **rim** is a popular type. The "straight-side," quick detachable, demountable rim is the rim now used most. One should always carry a tire inflated on a spare rim to replace a damaged tire. It can be mounted on the rim of the wheel, by loosening a few bolts and without having to use an air pump at all—see page 551. There is also an advantage in having the tires on all four wheels the same size.

Which is the best car to buy: This is a question we hear daily. After determining the size of car you want. I will tell you how I would settle the choice. If I were unable to decide otherwise. Go to a used car concern and ascertain which car brings the best price or what make of car sells more readily than others. This may help to answer this question.

†Selecting a Commercial Car.

There is a distinction between a truck and a delivery wagon. Some of the important points to be decided are:

What type of car for your particular needs—gas or electric?

What horsepower?

How many pounds capacity shall it have?

Should several cars be used or one big one?

Shall it be equipped with pneumatic or solid tires?

Can an inexperienced man be given charge of the running and repair work?

Is there any special equipment necessary for greater efficiency?

Should the car always be loaded to capacity?

Today there are motor trucks and delivery wagons of every conceivable size and design, therefore, it is the problem of the possible purchaser to choose carefully the kind of a car best fitted to serve their purpose with the greatest efficiency. It is a very common sight to see a heavy type of delivery wagon make a trip of several blocks and sometimes miles to deliver one or two small packages or baskets of groceries when one of the smaller types of commercial cars could have done it just as well and with greater efficiency, reducing materially the overhead cost. On the other hand, we have often seen a light delivery or a very heavy type of truck making a trip with an overload. This is just as impractical as an underload, for it will ruin the expensive motor equipment, making the car depreciation very considerable.

A very good rule to stick to closely is to have the car filled nearly to capacity on every trip that is made. A motor truck or delivery wagon should not be chosen having in mind a maximum or minimum load, but an average load. To get the greatest efficiency out of a commercial vehicle keep it loaded and moving the largest possible number of hours during the working day.

If electricity is produced in your own plant at a very low cost, and it is possible to secure a man who understands and can care for storage batteries, then it may pay to investigate the electric vehicle.

Judging and Testing a Second Hand Car.

In order that one can purchase a second-hand car with some degree of safety, as to its condition, the following tests are given. It will no doubt be impossible for the purchaser to make all of these tests, but it will give a general idea which can be applied to testing any car when overhauling.

General Condition.

Ascertain the age, make and type. Also the horse power of engine (see page 534), if car is an obsolete model or antiquated design, it will be a difficult matter to dispose of it later on at any price. Find out if the manufacturer is still in business (see pages 547, 548), so that parts can be obtained if required. **Do not judge a car by its outside appearance alone,** paint is ordinarily cheap.

Tires and Rims.

Many sizes of tires on some of the older cars have been discontinued (see page 554 and 555 for sizes now being made). You may have difficulty in obtaining tires.

Also learn the make of rim. The old style "one piece clincher" rim is obsolete, except on the Ford, Chevrolet, Maxwell and Overland Model "Four." The **modern rim,** is the "straight side," demountable type.

The best tire is the "Cord" tire (see page 559). The "fabric" tire is explained on page 564. Examine condition of the tires after reading page 566 and test for "stone-bruises."

Engine.

(1) **Test the compression of each cylinder** (see page 629). First learn what compression means—page 627. The compression test will indicate condition of the rings and cylinder walls and valves. If the **cylinder walls are scored or cut,** then this is an expensive job to repair (see page 653). If **valves leak,** then this is not so expensive—see page 630. If **rings leak,** then this will be an item worth noticing—see page 654, 655.

When running engine, if there is considerable smoke (see page 202), out the

*See pages 588, 589, why solid tires cannot be used on high speed vehicles.
†See pages 747, 825, 822 and 833 to 842 for truck and truck engines.

exhaust pipe and the smoke is blue or light in color, then there is too much oil in the crankcase of engine—or the pistons are pumping oil as explained on page 653—or the rings are loose or cylinder walls are scored. If smoke is heavy black, then the carburetor is feeding too much gasoline and can be adjusted. Many new engines have had the cylinders scored by running the engine too high a speed during the first 1,000 miles running and from lack of oil—see pages 489-203.

(2) **Test the bearings:** The best method for doing this is to make a long run, taking at least one or two fairly steep hills and note if engine knocks. By studying pages 635 to 639, you can learn to distinguish the cause of different kinds of knocks.

When testing for knocks, make allowances if engine is a four cylinder, especially of small size, and when taking hills slowly. Many four cylinder engines must get engine up to a fairly good speed to take a steep hill, as the power depends upon the momentum of fly wheel, whereas the six, eight or twelve cylinder engine should take a hill with less speed, without pounding or knocking, if spark is retarded properly—see pages 127 and 126, why.

(3) **Test the cooling system:** After making the above run, note if steam comes from the radiator at the vent or overflow tube or filler cap. If so, the engine runs hot and the trouble is one of the causes explained on page 579 "engine overheats," see also pages 189, 788, 319. Understand, an engine runs best at about 170° temperature but should not steam—see pages 185, 191. Also observe if there are leaks, usually the leaks are at the hose connections and can be tightened, but if hose is worn, replace it—see also, pages 193, 191.

The Clutch.

(1) **See if clutch slips** when taking a hill.
(2) **See if clutch drags when released.**
(3) **See if clutch "grabs" or is "fierce"**—see page 663.
(4) **Ascertain the type of clutch used in the car** by referring to index for "Specifications of Leading Cars." Then turn to page 661 to 668 and note the construction and troubles and remedies.

Transmission.

(1) **Test the gear shift while engine is running,** by shifting from reverse, 1st, 2nd, 3rd speed, to see if the gears can be changed without a clashing noise. If not, then the trouble may be due to the clutch pedal not being thrown far enough "out," or clutch "drags" or "spins," or the transmission or clutch shaft are out of alignment, due to worn bearings, or teeth of gears burred—see pages 669, 662, 663.

(2) **Test for worn or broken gear teeth.** With engine running slowly, place gears in 1st speed, place finger on gear lever—if there is a worn place at one point or all round the gear, it can be felt by the vibration. Try this on all speeds and reverse.

(3) **If transmission is noisy,** and there is plenty of oil in the transmission case; then the trouble is likely due to a broken ball or roller bearing or worn bearing.

If oil leaks out of transmission bearings see page 669.

Drive Shaft and Universal Joint.

(1) **Test for looseness**—see page 669 "end play." If excessive, the looseness is in either worn gears or bearings in transmission, loose universal joints or loose adjustment of drive pinion to the differential driven gear—see page 932.

Rear Axle.

(1) **Test adjustment of drive pinion**—see page 932 "noisy rear axle"—see also page 673, 674. On some cars, Ford for instance, there is no adjustment, therefore a new drive pinion (see fig. 25, 26, page 780) must be fitted.

(2) **Examine the differential by removing the cover,** if a "full floating" type (see page 669), or remove the axle housing, if a "semi" or "three quarter floating" type (see page 675, 780), in order to ascertain if any of the nuts are loose or small differential pinions are worn.

(3) **Test wheels for alignment**—see pages 683, 774.

(4) **See if axle shaft is bent**—usually at hub—see page 682.

(5) **See if oil is working out the rear hub into brake lining**—see page 678.

(6) **Test brakes**—see page 685.

Steering Device.

(1) **Test for play** and loose bolts and nuts—see page 691.

Miscellaneous Tests.

(1) **See if engine will idle** without missing—see page 171.

(2) **Test battery;** if a coil and battery ignition system—see pages 451, 453, 864D.

(3) **Test magneto;** if a magneto system of ignition, by idling and speeding up engine to see if missing of explosion.

(4) **Examine wiring** and see if oil soaked and ragged.

(5) **Test carburetor**—by idling and speeding up engine to see if even explosions and if engine picks up readily under load. Also note if carburetor air intake and carburetor mixture is heated, see pages 157, 159.

(6) **Examine spark plugs,** to see that gap is correct distance at points, (about .025") and that porcelains are not cracked.

(7) **Run car and test the mileage gained per gallon of gasoline.** This will require at least a 20 or 25 mile run. Many 6, 8, and 12 cylinder engines will not average over 9 to 14 miles per gallon—depending upon the condition of rings or leakage of gasoline into crankcase and size of cylinders and if roads or hilly or level.

(8) **Examine all bolts and nuts** on engine, springs, etc.

(9) **See that engine is properly oiled** and all parts of car greased—see also page 595.

(10) **If parts have been replaced,** as steering knuckles and spindles in front wheels, etc.—see that they are not made of castings instead of forgings.

INSTRUCTION No. 39.

THE AUTOMOBILE SALESMAN: Pointers, Suggestions and Advice. Advantages and Disadvantages of Mechanical Features of Different Parts of a Car. Addresses of Auto Manufacturers.

Suggestions.

To become a successful auto salesman one must necessarily know the principle and construction of all parts of a car, not merely the car you propose to sell, but other makes of cars as well.

In our instructions we have endeavored to teach you the principle and construction of the various parts of all cars; for instance, we illustrated and described the different types of drives usually employed; the different types of clutches, ignition systems, carburetors, etc. The engine was thoroughly explained. You learned that all engines work on the same principle but the construction may vary, in that the valves may be on the side or overhead, but the principle is just the same; also the same with the ignition and other subjects.

Therefore, taking it for granted that the reader has thoroughly mastered the different principles involved, he must now figure out why one system is better for a certain purpose than another. He must also familiarize himself with all makes of cars in order that he will know just why different manufacturers are using one system and others another. For us to point out such a comparison would require an extra book—therefore, we will suggest to those who have fully made up their mind to become auto salesmen, to obtain the catalogues of the various leading automobile manufacturers. These catalogues are easily obtainable by writing a postal card for them.

***Obtain the address of the various manufacturers.** I would suggest that the student write one of the following publications for a copy of their paper and the ads of the leading manufacturers will appear therein:

Automobile Dealer and Repairman, 76 Murray St., New York; Automobile, 239 W. 39th Street, New York; Motor Age, 1200 Michigan Ave., Chicago, Ill.; Motor, 381 4th Ave., New York; Horseless Age, New York, Motor World, New York.

After obtaining the catalogues of the various manufacturers, the next step will be to take one at a time and study the specifications of each car. This will give you the principle of construction of that make of car. If, in reading the specifications, you do not understand the meaning, then turn to the "index" in this book and find the explanation. For instance, suppose one manufacturer says the cylinders of his engine are cast "en-bloc," turn to index and find "en-bloc" and then read what "en-bloc" means. Each manufacturer will explain why his system is the best; for instance, one manufacturer may claim his three point suspension best; if you do not know what this means, then look it up in the "index." In this manner the salesman student will acquire a considerable knowledge of the various automobiles, and also from reading the claims of each manufacturer he will be able to discuss the relative values of these claims.

While all this may appear simple and an easy way to acquire the information, it possibly was not thought of by you, and if you will take the time and pains to do as directed it will no doubt be of great value to you.

Auto salesmen are usually employed on a commission. The commission is usually 5 per cent. Auto dealers who are agents for automobiles are always on the look-out for good salesmen, and to be a good salesman you must study the points of the car and be able to explain to a customer "why" your particular car is the best. He must also be able to close a deal; that is, after convincing the prospective customer that the car is the best, he must clinch the sale as quickly as possible.

A salesman who thoroughly understands his car and also understands the construction of other cars and can explain "why" his system is superior, is the valuable salesman. He must get his prospects the best way be can. Quite often a prospective customer will call at the garage and inquire about a car—it is then that the wide-awake salesman is there, ready with his courteous and agreeable manner and willingness to explain.

Salesmanship Pointers.

A man who intends to buy a car feels as though he is making an investment and he will, no doubt, investigate the merits of all cars. It is then reasonable to suppose that the salesman who most thoroughly impresses this prospect that he knows the construction of his car and can explain its good points, will make a greater impression on him. If the salesman is fortunate enough to be able to cultivate a pleasing personality then he will be all the more likely to make a valuable man.

Remember, the average man is generally governed by the wishes of his family—he may select a car himself but on having the women folks pass on the purchase nine times out of ten, they will go entirely for "looks;" therefore, it is essential that a salesman not only be neat and tidy himself, but he must keep the car he used for demonstrating perfectly clean and well polished, and above all, in perfect working order. Many a sale has been lost by nothing more than some trivial trouble as running out of gasoline or engine heating from lack of water. While these troubles would be insignificant with an experienced person, they would handicap a sale because the prospect would not know, but would think it a defect in the car.

Don't attempt to make your sale on the weakness of the other fellow's proposition but on the strength of your own. Understand, and admit to your prospect that all methods of construction have some advantages for certain purposes, else they would never have been manufactured. Be prepared to intelligently discuss the different features of the leading cars and to explain why the features of your car are—not the "best in the world"—but the best for that particular man's need. Once you make him feel that the car has special advantages for him personally, the sale is made.

Does your Customer Buy—or Do You Sell him?

Don't take it for granted when a man walks into your salesroom, or consents to a demonstration, that the car is half sold. This is merely an introduction and it is still up to you to make the sale. And you can't tell from the cut of a man's coat how much money he has in the bank.

Selling automobiles is a merchandising proposition pure and simple, and it is your duty to give the customer the same amount of courtesy and attention that he receives in any high-class store. Buyers appreciate courtesy.

As John Lee Mahin once said: "The buying unit is the family," and you should as soon as possible ascertain the purpose to which the buyer wishes to put the car—who else is to be considered besides the prospect—and then shape your arguments accordingly.

*See page 533 for addresses of manufacturers, and pages 543 to 546 for "Specifications of Leading Cars."

Here is an actual instance: A man walked into the salesroom of a certain dealer. He was just an ordinary looking human being, possibly not quite up to the average in appearance. He did not walk right up to the proprietor, but wandered around among the cars on the floor. The dealer happened to be talking to a friend and was in the middle of a detailed description of a show he had seen the night before—so he allowed the unimportant looking stranger to remain unnoticed.

The cars could not talk—they can't sell themselves unaided, so the man finally walked out.

Just across the street there was a salesroom with newly painted front. A car was displayed attractively in the show window and the atmosphere of the whole establishment was up-to-date business methods. The window was clean and the interior presented an attractive, enterprising, inviting appearance. When the stranger stopped in front of the window a salesman immediately opened the door and invited him to step inside, where he could get a much better view of the car.

Once inside, the salesman asked: "Have you ever had any experience in operating a car?" This was a safe question and it opened the door at once for a friendly discussion. Every man is eager to tell about his own motor experiences, even if he has at one time owned even an antiquated one cylinder model. As the prospect told his experiences the salesman, without antagonizing him, was able to draw comparisons between the car the prospect once owned and the new car on display. No matter what manner of car a prospect has driven, he does not want his judgment questioned.

Often a man is just as sensitive to criticism about his car, as he would be about his personal appearance.

During the discussion the prospective customer mentioned the fact that his old car was not adapted for use by his wife and daughter. On the strength of this bit of information the dealer then called the prospect's attention to the fact that the car on display permitted access to both front doors and allowed a lady passenger in the front seat with the driver to always be able to step out upon the curb, and not be compelled to walk around the car in order to get to the sidewalk.

As the conversation progressed the prospect was unconsciously being sold a car, and was led up to the point where HE HIMSELF asked for a demonstration, with the result that the ENTIRE FAMILY AS A UNIT bought the car.

The salesman sold the car without the prospect realizing that he was being forced to buy. THE MAIN THING IS TO ALLOW THE PROSPECT TO THINK HE IS BUYING THE CAR, WHILE IN REALITY YOU ARE SELLING IT TO HIM.

The moral of all this is, that no matter how good your car may be, it cannot possibly sell itself alone. This is just an example of one type of buyers—the man who has owned a car and who goes "shopping" when he buys.

Know Your Man before You Try to Sell Him.

By using a little tact, any dealer can ascertain the purpose to which the prospect intends to put the car be buys—whether or not it is for family use, personal pleasure, cross-country touring or for business purposes.

Experience in selling motor cars, teaches that all prospective buyers may be separated into five main classes:

(A) Price tag—the man who is looking for a bargain regardless of the age and often regardless of the condition of the car—just so that he gets a car that will run.

A second-hand car or any old car will do.

This class of buyers are limited usually to the "wage earners," who hesitates between a motorcycle and a second-hand motor car. Before wasting any time on him, FIND OUT HOW MUCH REAL MONEY HE HAS to invest and unless he has cash on hand, pass him up, courteously but quickly. REMEMBER YOUR TIME IS VALUABLE—YOUR EXPENSES ARE GOING ON WHILE YOU ARE TALKING TO HIM.

(B) Second hand fiend—this man is a shrewd buyer, he is the David Harum of the automobile business, usually with little money AND TRYING TO UNLOAD ON TO YOU. In the first place he bought a much-used second-hand car. Then he invested a little more money and traded it with a friend for a better car, hoping that he could unload his new purchase on you by paying a small amount of cash and getting a brand new, up-to-date model.

Don't let your desire to move a car from the salesroom to the street, lead you into an unbusinesslike transaction. Just remember that the second-hand car may prove a "white elephant" on your hands. (It costs just about as much money to keep capital tied up in a second-hand unsalable car, as it would to feed and care for an elephant.)

Rather than do this, LET HIM GO. CONCENTRATE YOUR TIME AND ENERGY UPON THE MAN WHO HAS CASH IN THE BANK. It is just as much to know where not to work as to where to work.

There are exceptional cases, however, especially where a man owns a car that YOU sold him, and who wants to buy a new model from YOU.

Tack this up on the wall, over your desk: "A certified check in your bank book ready for deposit, is worth more than a second-hand car on the floor."

(C) Appearance and pleasure—this man is influenced largely by the lines of the car and the anticipation of the pleasure he is going to get out of it. He is usually in a hurry to buy. He belongs to that rapidly disappearing class that used to walk in and buy a car in ten minutes. It does not require a salesman to sell this man. But the wise, hard-headed, shrewd dealer with a view to his permanent success, will analyze this man's requirements and sell him the car best fitted to his needs, so that the sale will not act as a boomerang.

(D) Social prestige and reputation—this is the man who usually buys a car to please his wife with social aspirations. She knows absolutely nothing about a car, but has received the impression some way that "to be anybody" she must have a name-plate with an artificial value, rather than a car of merit. How have you been handling this class of buyers?

A thorough analysis of sales made by successful dealers, proves that this prospect if handled right, is always easy to sell. The approach in this case is through the man of the house who realizes that $5,000 is 5 per cent of $100,000, and when shown point for point that a car selling for $2,750 will give as good or better service, with accompanying elegance and atmosphere of refinement, he will not WASTE two or three thousand dollars on some fancy of his household.

No matter how much money this man is worth, he is NOT willing to waste two or three thousand dollars on a nameplate. YOU AS A DEALER, WILL SELL MORE CARS AND MAKE MORE MONEY BY GIVING YOUR CUSTOMERS REAL VALUE.

(E) Service and business—this man represents the LARGE majority of buyers today. HE IS MOTOR-EDUCATED. He has probably owned a car before or else has made a very thorough study of motor car construction and is taking the advice of friends and benefiting by their experience. While this man is open to reason, he is not going to buy in a hurry.

Before deciding he will get underneath the paint and the hood. Your first move is to as tactfully as possible ascertain if influence is being brought to bear upon him in favor of a particular car by some neighbor or friend Then you will know what cars you are in competition with and what bias and prejudices you will have to overcome before you can make the sale.

Probably the neighbor or friend of this prospective buyer owns a car that is not up-to-date, although it is apparently giving good service. AND RIGHT HERE IS WHERE YOUR SALESMANSHIP IS TESTED.

Prove to this prospective buyer that the car you are selling with left-side drive and center control (for example) is a year or more ahead of other cars, as a consequence next year it will still be up-to-date and will also demand a much higher second-hand value, taking it for granted, of course, that you are able point for point, to show where your car will give as great or better service than the car owned by the neighbor or friend of your customer.

All buyers—the majority of buyers are influenced greatly by printers' ink. They have more or less definite opinions of various cars, formed by what have read about them. Therefore, as a fundamental principle, YOU SHOULD NOT RISK YOUR TIME NOR MONEY ON AN UNKNOWN CAR. A car, whose name is a household word, is naturally much easier to sell than a car that the prospective buyer never heard of before. THE WELL ADVERTISED AND TESTED CAR MEANS QUICKER AND MORE FREQUENT SALES. Especially is this true with a car that has demonstrated its superiority in public contest, such as races. Remember, A QUICK SALE IS MORE PROFITABLE THAN A SLOW SALE.

The modern automobile dealer, is the man who is equipped to TAKE CARE of his customers, especially if the buyer intends to drive the car himself. In fact, most every up-to-date dealer now has an efficient service department.

A little service and assistance gives the owner the feeling of confidence and GOOD WILL toward both you and the car. Service means satisfied customers, and satisfied customers means a permanent, profitable business for you. Service also converts probable knockers into positive boosters. If your success is to be lasting every man to whom you sell a car must, one year or more from date of sale, be as enthusiastic as the day in which he bought the car from you. This is possible by first giving real value and second by taking care of him. (from booklet published by National Motor Car and Vehicle Co.)

*Advantages and Disadvantages.
If You are Selling a Car Understand Its Features.

The auto salesman must be able to talk on almost any subject relative to the construction of various cars. He must know the advantage and disadvantages of the features of different cars which will be suggested by a prospective customer. For instance, if the salesman is selling a car with a four-point suspension, he must know the advantage of the four-point suspension and the disadvantage of the three-point and vice versa.

A few subjects will be treated in the following matter. For further information I would suggest that every auto salesman make it a point to accumulate the catalogs of all motor car manufacturers, and in this way he will see the different features discussed by the various manufacturers and will gain many valuable pointers.

Long Stroke vs. Short Stroke.

The advantages of the long-stroke over the short-stroke type of engine are:

Leverage. Given a certain expansion force within the cylinder, the travel of the piston being longer, and transmitted to a longer crank, it operates on a longer lever.

Greater expansion. Given a charge of a certain volume at the time of ignition, it will expand to a greater volume (before the opening of the exhaust valve) in a long-stroke engine than in a short-stroke one, thereby using more of the energy generated in the expansion of the gases. The theoretical idea of any heat engine is to use as nearly 100 per cent of the expansion of the charge within the engine as is possible. This accounts for the greater efficiency of the compound steam engine over that of the single-acting type. This type of engine is substantially an elongated-stroke engine, the only difference being that the low pressure portion of the stroke is in a larger cylinder than the high-pressure portion. In the long-stroke engine, this super-expansion takes place in a less degree in the same cylinder, so that at the beginning of the stroke the cylinder is a high-pressure cylinder, and at the lower portion of the stroke, it is a low pressure one.

It has been found in high speed express locomotive practice, that the short-stroke single-expansion engine, while it produces a very low rate of efficiency and is enormously wasteful, the actual results in high-speed, light-draught work are superior to those of the more efficient type, as only the very cream of the expansive energy is used. This has been found to apply in the same way to gas engines, and for racing work, the short-stroke, while less efficient, more wasteful of fuel, and less flexible, has been found to give better results than the long-stroke type. This is the reason some of the prominent European makers produce stock cars with small bores and long strokes, while their high-speed cars are the reverse. Road racers, on the other hand, generally revert to the preponderance of stroke again, as the short-stroke type is not sufficiently flexible to produce good reults, unless built in enormously large power-units.

This was well illustrated in a recent automobile road race; where even the high horsepower cars were found to have a preponderance of stroke, while the lighter ones were all designed with long strokes. One make, whose sprint cars, designed for excessive speed for short distances—below 150 miles—have larger bores than strokes; while those designed for the long-distance high-speed grinds, have longer strokes than bores.

Slower crank shaft speed for the same piston speed: It has been found that speed in revolution per minute is not an accurate standard by which to gauge the power of an engine; but that piston speed in feet per minute, in combination with bore and number of cylinders, is the true measure of an engine's power. It is thus seen that two engines of the same design except as to stroke, will give the same power, (disregarding considerations of expansive efficiency) at equal piston speeds. But the long-stroke engine in reaching the same piston speed as the short-stroke type, will revolve much slower. The advantagès of slower speed are, of course, well understood. If compared to crank shaft speed, the long-stroke type will give greater power, less speed, less friction.

There are other advantages, but the above are among the most important. In considering them, it must be remembered that the comparison is made in the light of efficiency, which is under stood to be made up of the factors; horsepower per gallon of gasoline, horsepower per pound of weight, horsepower per cubic foot of space occupied, durability and flexibility. In a racing motor, this term would not have the same meaning, nor would all racing motors come under the same category, as explained above.

Advantage of short-stroke engines are higher speed with smaller pistons, therefore less wall pressure and less liability of ring leakage.

There is less exposure of metallic surface less movement of the piston and less angularity, that is to say, as the crank is relatively short, the connecting rod is thrown less out of its perpendicular position and therefore the piston is less violently pressed against the walls of the cylinder, with the result that there is a saving in frictional loss which is one of the greatest troubles we have to contend with, in striving for higher efficiency. Another point is, that with a short stroke it is possible to have piston pin higher up, this preventing the tendency of piston to chatter which it does when pin is too near the lower end.

Five-Bearing Crank Shaft.

Is a five-bearing crank shaft more efficient and durable than the three-bearing type? Is there less liability of loose bearings in the five bearing than in the three? Is it not true that it is usually the connecting rod bearings and not the crank shaft bearings that wear first and therefore the number of crank shaft bearings has nothing to do with this trouble?

Ans.—There are advantages on both sides of the engine journal question. The advantages of the five-bearing type rest on the fact that there is a longer bearing surface, hence more provi-

*See page 255 for Advantages and Disadvantages of different Ignition Systems.

sion for wear and (more work in fitting the bearings when worn.)

The following are the advantages and disadvantages of the three and five-bearing crank shaft as given by the Continental Engine Co. and the Rutenber Engine Co.:

The subject is one that is open to much discussion and for 4-inch bore and less, the three bearings are undoubtedly an advantage over the five on account of the simplicity, and yet the distance between supports is sufficiently small to overcome the vibration set up in high speed running.

On larger sizes, if the crank shaft is made sufficiently strong and the bearings of ample width, the three-bearing engine, as has been shown, is very satisfactory, but in these sizes it is an advantage to have light weight and yet stability, and in consequence, the five bearings often prove better in the argument that they can get their surface without heavy crank shafts and yet be sure against vibrations.

The advantages of the three-bearing crank are as follows: An engine so equipped is slightly cheaper to build, easier to scrape bearings in and a slightly shorter engine can be designed by using the three-bearing shaft.

The disadvantages are: The wear is slightly greater at higher speeds, and to obtain same strength as a five-bearing shaft it requires larger diameter bearings, hence higher peripheral speed.

The advantages of the five-bearing shaft are: Less distortion and less wear at high speeds only; and less heat, that is; if properly fitted.

The disadvantages of the five-bearing shaft are: The initial cost in machining and fitting. Would, however, recommend the three-bearing job for commercial purposes.

Offset Cylinders.

See page 81 also fig. 5, page 82 advantages are: Less liability of back kick, reduced wear on bearing surfaces of cylinder walls, connecting rods and crank shaft, less liability of the engine to stall when car is running slowly on high gear.

Four vs. Six Cylinders.

The advantages of the eight over the four or six is in flexibility of control, and lapping of power strokes,* consequently much simpler in points of both operation and repair; more power is in a given space, especially as regards length; the weights on account of heavy fly wheel in the four will be approximately the same; better facilities for uniform distribution of the gas to the various cylinders; more rigid crank shaft.

The advantages of the six cylinder over the four are: Flexibility of operation due to continuous torque, allowing a greater range of speed without resort to gear shifting; greater power at low speed of engine; as, for instance, in hill climbing; due to the lapping of power strokes, less vibratory strain on the gearing in the transmission and differential drive and pinions as well as the universal joints and to some extent the tires on rear wheels. (See pages 123 and 126.)

Advantage of the four cylinder—principally economy and less number of parts.

Advantages of the T-Head Cylinder.

The principal advantage of the T-head motor over the L-head is that the valve area is larger than with the L-head with the valves side-by-side (see page 81 for comparison.) Another advantage is that the gas has a direct passage from one side of the engine to the other, and the plugs, situated in the inlet valve pocket, are not subjected to a carbon-laden blast of burned gas at the exhaust. The exhaust is more complete, as the outward passage at one side can be accelerated by the inward rush of fresh gas.

The disadvantages are that the volume of the valve-pockets is increased, thus providing more space for burned gases to lurk in than with the L-head, and that the engine so constructed requires two cam shafts and with their gears, bearings and casings, are heavier, for the same power, and much more expensive to manufacture.

The "L" head is easier to construct and requires less parts and if properly designed so that gas pockets over valves is correct and valves properly timed—it is more suitable for touring and general work. See index for "compression" for explanation of valve pocket.

The overhead valve engine is more powerful and efficient owing to the relative position of valve to combustion chamber. The valves however, are usually noiser and the compression usually higher and very hard on spark plugs—see index for "spark plugs," "valves" and "compression" which will treat on overhead valve advantages and disadvantages.

The Eight Cylinder Engine.

The advantages of the eight over the four or six is clearly brought out in text on pages 126 and 127. Better balance, more firing impulses and torque are the chief advantages.

Advantages: Greater power for a given weight than the six-cylinder design.

Eight cams instead of 12, and also shorter camshaft.

Engine is considerably shorter than six-cylinder models.

Shorter and lighter crankshaft.

Shorter and lighter crankcase.

Uniformity of torque, which is better than that of six-cylinder engine.

Suitability of design for reasonably high compression.

High mechanical efficiency.

Disadvantages: Further complication owing to more cylinders to care for.

Cost of and difficulty in manufacturing special design of connecting rods.

Reduction in area of big-end bearings.

Extra weight of cylinder block in ratio to power, as compared with the four-cylinder or six cylinder design.

Requires better design and more careful workmanship.

Balanced Crankshaft.

A balanced crankshaft will make a good engine run smoother at high speeds, but a properly designed engine will run at high enough speeds with no additional benefit from an abnormal shaft, and no system of balancing can increase power except at quite high speeds.

If an engine has an essentially weak shaft the whipping of that shaft at high speeds places stresses on the bearings and causes power to be wasted in friction. By balancing the shaft we may stop the whipping and so raise the power, but this is only a side issue; the real value of a balanced shaft is the greater smoothness of the engine at the highest speeds the owner is likely to use, see pages 78 and 122.

The Floating Axle.

The advantages of a full floating axle over a semi-floating axle are, that whereas in the simi-floating type of axle the wheels are secured rigidly to the drive axle and are supported on bearings between the latter and the axle tube, the drive axles of the floating axle are flexibly clutched to the wheels, run on separate bearings and carry no weight. The semi-floating drive axle must not only transmit the driving torque, but must support the wheels besides, while the floating drive axles receive tortional strains only (the weight of the car being carried by the axle housing). The bearings on which the wheels of a floating axle are mounted are outside of the axle tubes, and easily accessible, while those of the semi-floating axle are between the drive-axles and the tube, and hence are not as accessible. The drive-axles on a floating axle may be removed, permitting the differential to be taken out without disturbing the wheels or their mountings. This is, of course, impossible with a semi-floating axle, as in this type the housing must be entirely removed from the car, together with the wheels, axle and differential.

The expense of manufacture of a semi-floating axle, however, is much less than that of the floating type, and as they have given satisfactory service where they have been properly designed, many manufacturers do not deem the greater

*See page 126.

cost of the floating type warranted. For this reason, in late years, a compromise type has been evolved, known as the three-quarter floating type, which possesses some of the advantages of both. (Write Timken Axle Co., Detroit, Mich., for description of their axles) see page 83, also charts 272 and 272A.

Three-Point Suspension.

Three-point suspension is a general term that refers to the suspension of the power plant by three points, and has several applications to motor car design. The commonest of these is the three-point support of the engine, and three-point suspension of the frame. When three-point suspension is specified as a separate feature, it is understood as referring to the frame suspension. When it is included in the description of the engine it refers to the engine. (See page 11 and 72.)

The advantages advanced for three-point suspension are as follows: An engine mounted to the frame by three points is not subjected to any strains upon the warping of the frame. The jarring from the road is less severe on a three-point suspended frame, because at the end at which it is suspended by one point, lateral motion of the axle has very little effect upon the frame, so that in going over a bump on one side of the road it is seriously felt but once, although both axles are deflected by it. Three-point suspension permits of flexibility of the frame without loss of strength, thereby saving weight, as it requires greater strength to support a load rigidly, than it does flexibly.

Many prominent motor car designers are adherents to the four-point form of engine support, not from any objection to the three-point principle, but because in practice the four-point support has been found satisfactory.

The Packard for many years used a four-point engine support on its four cylinder cars, but found it advantageous in the longer six cylinder engines to use the more flexible form of suspension, viz.; the three-point.

*A Few Words to the Young Man Just Starting.

There is an old saying to the effect, "All the world loves a lover." There's another one, just as true, to the effect that " all the world loves an OPTIMIST."

It pays to be optimistic! "Be pleasant every morning until 10'clock, and the rest of the day will take care of itself."

Optimism is its own reward. Be pleasant and courteous at all times regardless of the kind of a reception you receive and in nine cases out of ten the coldest turndown will develop into a warm welcome if you exercise the proper amount of diplomacy and tact in approaching even the most irritable prospect. Even if you don't succeed in securing encouragement on your first call, you leave behind you a favorable impression which will be working in your interest and will do a whole lot towards landing the order for you on your second visit.

Every day of course, cannot be a record day in selling cars. We all have what seen to be our unlucky days, and you may occasionally have the same experience, but the very next day may develop into your record breaker, and more than offset the poor results of the preceding day.

It is the general average which counts. You may have what seems to be two or three very unlucky days in one week and all of the other days may so far exceed the result of the unlucky days that the average of the week will be up to your high water mark. Every business man will tell you that he has days and weeks when it seems that "the bottom has dropped out of business," but yet at the end of the month or the end of the year they find the general average is very satisfactory after all.

That's the way you'll find it in all lines of work. You will very seldom find real cause for discouragement, and all of these experiences in overcoming difficulties, and making the good days offset the bad days, is the sort of EXPERIENCE that will be of great value to you in your future work along any line.

Some of our readers, who are now among the greatest producers, had what seemed to be more than their share of unlucky days at the start. Some of them wrote us at the end of the first week that they didn't believe they could ever make a success of the work and they were on the point of giving up in disgust. They didn't give up, however. They "stayed with the ship." They started the second week with renewed determination to succeed. And they DID succeed. They found that determination and persistency were the qualities that always WIN—just as they will win for YOU.

As previously stated, the first essential is to know your car. Be prepared to intelligently present your proposition and know how to overcome any objection when it is presented. Be convinced, in your own mind, that you have a proposition which justifies the very best effort you are capable of putting forth. Sell to YOURSELF first— then you'll find it an easy proposition to sell to others, and above all else, do not forget for one moment that you are the representative of the greatest industry the world has ever known.

Where to Obtain Further Information or Catalogues.

Automobiles; write to one of the auto magazines (see page 529), and see also automobile manufacturers addresses—below.

Ignition; for catalogues on ignition, see ignition subject and page 288.

Electric starter, etc.—see page 373.

Carburetors; see page 162, for address of manufacturers.

Where to obtain parts of cars no longer manufactured—see page 547.

By addressing the publisher of this book; addressing your correspondence to A. L. Dyke, Publisher, St. Louis, Mo., "Information Department," and enclosing stamped and self-addressed envelope for reply, we will gladly furnish you with any information we can. At certain seasons of the year, inquiries of this nature are very numerous but we answer just as soon as we can

Specifications of leading cars—see pages 543 to 546.

Addresses of some of the Leading Automobile Manufacturers.

*See Instruction 44.

The horsepower of a gasoline engine is dependent upon the following things: number of cylinders, area of piston heads, average number of pounds per square inch exerted upon the piston during the working strokes, and the revolution per minute of the engine.

S. A. E. means Society of Automotive Engineers. This formula was orignally adopted by the A. L. A. M. (American Licensed Automobile Manufacturers) and later by the S. A. E.

It has been worked out upon the assumption that the piston speed is 1000 ft. per min. and that the mean effective pressure is 90 lb. per sq. in. Inasmuch as the piston speeds of modern engines run up as high as 1500 to 2000 ft. per min., and the mean effective pressures per sq. in. go up to 110 to 120 lb., you can see that this formula is not altogether accurate, as to the actual horse power would be considerably more, however it is used for estimating and serves its purpose.

In order to compensate for the inferior quality of gasoline, some manufacturers have reduced the area of the combustion chamber so as to give a high compression.

S. A. E. Horsepower Table.

$$\text{H. P.} = \frac{(\text{DIAM. IN INCHES})^2 \times \text{NUMBER OF CYLINDERS}}{2.5}$$

*Piston Speed.

When this S. A. E. formula was first adopted most engines developed their horse power at 1000 feet of piston travel per minute. Therefore it was worked out under the assumption that the piston speed is 1000 feet per minute.

The factor of piston speed takes in both the length of the stroke and speed of the crank-shaft in rev. per min. and mean effective pressure of 90 lb. to the square inch.

The shorter the crank the quicker it can be turned, the longer the crank, more piston travel per stroke, therefore crank can travel slower and still the piston will travel the required distance.

As an example; suppose the stroke of an engine is 4 inches, it would have to make 3 strokes to travel 12 inches or 1 foot, because each stroke is 4 inches in length. Take on the other hand, an engine with a stroke of 6 inches; it would have but 2 strokes to make per 12 inches or 1 foot of travel. Therefore it is evident from the above that the shorter the stroke, the faster crank must move to cause piston to travel 1000 feet in the specified time.

A given amount of power can be developed in cylinders of either large or small diameter. Thus there is the example of the stationary gas engine. To obtain for example, 10 h. p. from this type of engine a very large cylinder and comparatively slow speed would be employed with a maximum speed of perhaps 300 to 600 r. p. m. A modern 10 h. p. automobile engine on the other hand has four very small cylinders, but a high speed say, 1500 to 2000 revolutions per minute. The individual power impulses are very much weaker than those of the large slow speed engine, and consequently its parts can be made much lighter and smaller, as the shocks and stresses that have to be sustained are proportionately much less.

How To Figure The S. A. E. Formula.

This formula is used by all leading manufacturers and by the license offices in different cities.

$$\text{H. P.} = \frac{D^2 N}{2.5}$$

For example: What is the estimated formula h. p. of a four cylinder engine which has a 4 inch stroke?

By referring to the table, to the left, one 4 in. bore cylinder is 6.4 and 4 cylinders of 4 in. bore is 25.6 h. p. This is arrived at as follows:

D^2 (diameter squared) $4 \times 4 = 16$.
N (number of cylinders) $16 \times 4 = 64$.
2.5 (constant) $64 \div 2.5 = 25.6$ h. p.

It will be noted that the stroke of the cylinder was not taken into consideration at all.

Another Formula (not the S. A. E.).

The following formula takes into consideration the stroke as well as the bore and also the speed.

$$\text{H. P. Formula: } \frac{D^2 \times N \times L \times R}{C} = \text{H. P.}$$

This means square the diameter or bore of the cylinder (D^2) and multiply the result by the number of cylinders (N) and multiply this result by the length of stroke (L) and multiply this result by the revolutions (R) per minute of crank shaft, then divide this total result by the "constant" (C) below.

The "constant" for 4 cycle engine is 13,000.
The "constant" for 2 cycle engine is 10,000.

Example; suppose we have a 4 cylinder engine—4 inch bore (diameter) and five inch stroke and 1000 revolutions per minute—what is the horse power?

4 x 4 equals 16 (squaring the diameter D^2).
16 x 4 equals 64 (result multiplied by number of cylinders "N").
64 x 5 equals 320 (result multiplied by length of stroke "L").
320 x 1000 equals 320000 (result multiplied by number of revolutions "R").
320000 divided by the "constant," 13,000 will give us 24.6 h. p. for a 4 cycle engine.
320000 divided by 10,000 will give us 32 h. p. for a 2 cycle engine.

The "constant" is a figure arrived at by the founder of the formula. You will note there is a difference of 1 h. p. between the horse power figured with this formula and the S. A. E. formula. There is usually a difference with all formulas.

CHART NO. 224—Horse Power Formulas. *See page 540 for table of piston travel in feet per min.

**Now known as the N. A. C. C. (National Automobile Chamber of Commerce) formula.

INSTRUCTION No. 40.
HORSE POWER, TABLES AND GENERAL DATA.

Power, Work, Horse Power and Torque.

Power: In order to understand power one must consider that its definiton is the **rate (speed) of doing work.**

Work is a force acting through a distance, for example, if we lift 10 lbs. through 2 feet, we accomplish an amount of work equal to 10 lbs. × 2 ft. or 20 **foot lbs.**

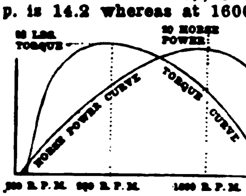
The next factor is the rate (speed) of doing this work. For example, suppose we lift 10 lbs. through 2 feet in 10 minutes, our power is 10 lbs. × 2 ft. ÷ 10 min., or 2 **foot pounds per minute.**

Horse Power (H. P.) is then a unit of power, namely the accomplishment of 33,000 ft. lbs. of work in 1 minute, expressed as 1 horse power (1-H. P.) The horse power unit is used in motor work as a standard rate of doing mechanical work, equal to 33,000 pounds (or weight) raised through a height of 1 foot in 1 minute; or any proportionate ratio which multiplied together equals 33,000 ft. lbs. in the same time, is also equal to 1 horse power. The horse power has nothing to do whatever with the power developed by a horse—but in the days of Watt and early engineers (of the 18th century) the work in ft. lbs. capable of being done by an average draught horse in 1 minute was taken as the unit. of power. The French horsepower equals 32,549 ft. lbs. of work in one minute, expressed as 1 horsepower, and is thus less than the English standard.

Torque is the product of force × by the distance at which it is exerted from the center of rotation, for example suppose we have a 1 foot pipe wrench and we apply a force of 40 lbs. on the end of that wrench, we will then exert a torque of 40 lbs. × 1 foot, or 40 ft. lbs. of torque. On the other hand, if we had a 2 foot pipe wrench and exerted 40 lbs. on the end of it we would exert a torque of 40 lbs. × 2 feet, or 80 foot lbs. torque. This explains why it is easier to unscrew a pipe coupling with a 2 foot wrench than it is with a 1 foot wrench—the torque is greater.

When we say an engine developes 83 ft. lbs. torque, we mean that at a distance of 1 foot from the center of the crankshaft the engine would exert a force of 83 lbs. or at a distance o.f 83 feet from center of crankshaft the engine would exert a force of 1 lb. For instance. suppose we wished to stop an engine which exerted 83 ft. lbs. torque, by means of a pipe wrench. If a 1 foot wrench was used, by exerting a force of 83 lbs. on the end of the wrench it would stop the engine. Or if an 83 foot wrench were used, a force of 1 lb. exerted at end of wrench, would stop engine.

On the Ford engine the torque at 900 r. p. m. (see illustration of curve), is 83 ft. lbs. and the h. p. is 14.2 whereas at 1600 r. p. m. the torque is only 65 ft. lbs. and the h. p. is 20. Also note that the torque increases up to 900 r. p. m. then falls off and also note that the h. p. increases up to 1600 r. p. m. then falls off. (See also page 770).



To the layman it would appear that the greatest pull or force exerted would be at 1600 r. p. m., but such is not the case. The greatest pull on this particular engine is at 900 r. p. m.

The reason why greater h. p. can be developed with lesser torque is due to the factor of speed, which we have already seen is one of the items effecting power.

For example the engine at 900 r. p. m. is like Tom, who can carry 150 lbs. of bricks (we will term the carrying capacity of Tom torque), at a speed of 4 miles per hour. Suppose the bricks had to be moved one mile. Tom could move 4 x150=600 lbs. of brick in 1 hour.

The engine while running at 1600 r. p. m. is like Phillip, who can only carry 125 lbs. of bricks but can run, at a speed of 6 miles per hour. Philip could then move the bricks a mile at the following rate of speed; 6x125=750 lbs. of brick in 1 hour. Therefore while Phillip developes less torque, he developes greater power.

Therefore, at 900 r. p. m. the load carried (torque) is greater. but speed is less and the rate of doing work is less. At 1600 r. p. m. the load carried (torque) is less but the speed and rate of doing the work (H. P.) is greater.

The reason why engine developes less torque at 1600 r. p m. than at 900 r. p. m., is due to the fact that the cylinder receives a smaller charge of gas per stroke at 1600 than at 900 r. p. m., due to the inertia and the friction of the gases passing through manifold and valve. At the lower speed. the effect of inertia and friction is small, allowing a considerable quantity of gas to be introduced into the cylinder at each inlet stroke. while on the other hand, at 1600 r. p. m. the high velocity of the gas causes a considerable amount of friction and the effect of inertia (tendency to move slower) is greater which decreases the charge of gas entering the cylinder. This also accounts for the **great** decrease of torque and consequent falling off of power (H. P.) after 1600 r. p. m. Therefore this engine exerts its greatest pull at 900 r. p. m. and the futility of racing engine when attempting to pull out of a hole is apparent. See also, page 770 for table of engine speeds and torque.

The Dodge engine, which has larger cylinders and valves, exerts its greatest pull (torque) at from 1100 to 1400 r. p. m. wheras its greatest speed and h. p. is at 2200 r. p. m.

Power and Pressure Abbreviations.

Brake horsepower (B. H. P.): Power delivered at the cranshaft—see page 861 and 537.

Indicated Horsepower (I. H. P.): Power delivered by the gas inside the cylinder to the piston—see page 863.

If an engine developes 10 indicated horsepower and it takes 3 horsepower to drive itself. the crankshaft would deliver 7 h. p. and the rating of engine would be 7 **brake** horsepower or 10 **indicated** horsepower.

To estimate the h. p. of an engine within a reasonable degree of accuracy. one of the several formulas promulgated for the purpose is the N. A. C. C. page 534.

To actually calculate the h. p. the brake test must be made with a mechanical machine as a "prony brake test" page 537, or "dynamometer test" page 536.

Thermal efficiency of an engine—see page 587.

Mechanical efficiency of an engine—see page 863

Compression pressure is the pressure of the gas after being drawn into the cylinder and compressed in the combustion chamber by the up compression stroke of piston. This varies with the quantity of gas drawn into cylinder, speed of piston, size of combustion chamber and condition of valves, rings and tightness of parts—see page 627 for average compression, see also page 640. 626.

The expansion pressure (often termed explosion pressure) would be the **maximum or greatest** pressure immediately following the combustion or burning of the gases. This pressure is many times greater than compression pressure. This expansion pressure (gas expands when ignited and heated) continues but diminishes throughout the entire power stroke.

—continued on next page.

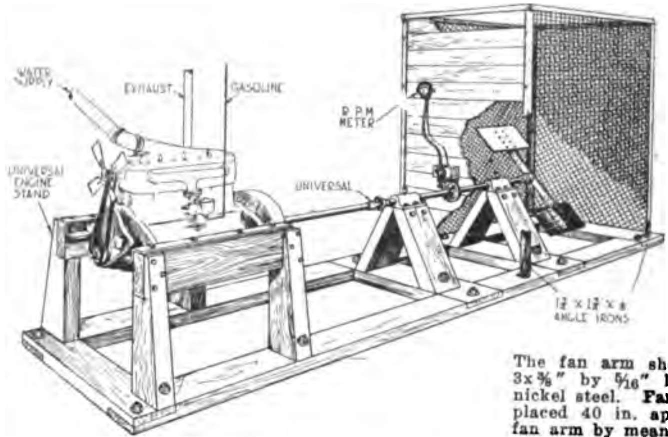
—continued from page 535.

Mean effective pressure (M. E. P.): During the entire cycle of a gas engine, the cylinder is subjected to many variations of pressure. We have seen that during the power stroke, the pressure decreases as the piston proceeds along its stroke. All of this pressure causes the engine to deliver power. In the same way, during compression stroke the pressure gradually increases as the piston travels upward. All of this pressure hinders the engine from delivering power and should therefore be considered as a negative power. Now, if we average up all the pressures during a cycle and substract those which hinder the engine from those which help it, (the power stroke is the only stroke which helps), we will arrive at the M. E. P. that is, the average or mean pressure which is effective in producing power.

Horse power and revolutions. The gasoline engine, within certain limits is dependent upon engine revolutions for power. If the revolutions are not maintained to a certain speed, especially on 1, 2 and 4 cyl. engines, the power is not sufficient to start car or climb hills. It is for this reason that transmission gears are necessary.

In mentioning the nominal horse-power of an engine, i. e., the catalogued h. p. it is intended to convey that the engine develops this power at 1000 feet of piston travel (see page 534). This by no means indicates the maximum, however. For instance, a Hudson engine develops 35 h. p. at 1000 r. p. m. and 77½ h. p. at 2400 r. p. m. and then drops off to 75 h. p. at its highest speed of 2700 r. p. m.

The Fan Dynamometer.



Consists of a fan, driven by engine. The power required to turn the fan increases with the speed and at all times bears a definite relation to the speed. Hence, knowing the speed, it is possible to determine the horse power being developed—see r. p. m. (revolutions per minute) and h. p. table below.

The speed is shown by means of a speedometer, driven from the fan shaft, but registering revolutions per minute instead of miles per hour.

Engine is bolted to a frame. The **drive shaft** is shown. The **fan shaft** is carried on two heavy pillow blocks bolted to wooden supports with ball or roller type bearings if possible. The fan arm should be of solid bar nickel steel, 3x⅜" by 5/16" long. The hub should also be of nickel steel. **Fan blades** are heavy sheet aluminum, placed 40 in. apart on centers, and bolted to the fan arm by means of angle iron strips that are riveted back to back on the aluminum blades. To avoid accident the fan is enclosed in a cage of mesh wire netting.

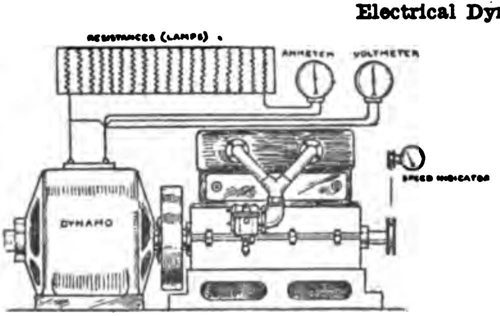
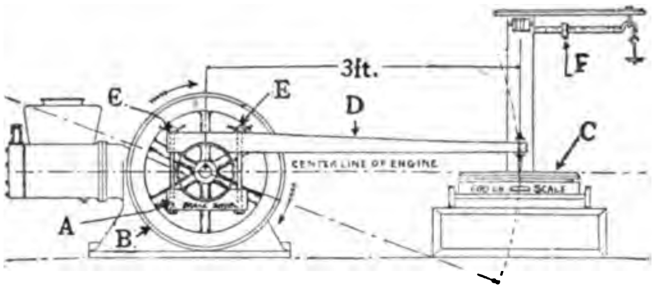
Electrical Dynamometer.



The method for testing the h. p. of a gasoline engine with an electrical dynamometer is as follows:—The engine is belted or (preferably) coupled direct to a dynamo machine. Connected up with the dynamo are two specially accurate electrical measuring instruments, one a voltmeter and the other an amperemeter. The current which the dynamo produces when driven is used up by either a group of lamps or a set of wire or liquid resistances. The amount of work the dynamo will do, such as lighting lamps, etc., depends on the power put into it from the engine. **It is easy to convert electrical power units into mechanical units. Thus:** amperes x volts equals watts, and there are 746 watts to a horsepower, so that by simply taking the readings of the voltmeter and ammeter the amount of power the dynamo is giving out is at once calculated. The dynamo, of course, does not transform the whole of the power put into it into electricity, but it may transform somewhere near 90 per cent of it. Certain mechanical and electrical losses occur in the dynamo, but these are calculated beforehand. **Hence,** knowing exactly how much of the power, put into the dynamo is lost or wasted and the maximum **amount** given out, will give the power actually produced by the engine.

CHART NO. 224A—Gasoline Engine Horse Power. The Fan Dynamometer. Electrical Dynamometer.

*Fan Dynamometer from Motor World by Mr. S. T. Williams (used by Reo Service Stations).



Prony Brake Test

Is one method of testing the brake h. p. and torque of an engine.

One horse-power is defined as the power that will raise 550 lb. 1 ft. high in 1 sec., or, as the case may be, 33,000 lb. 1 ft. high in 1 min. The power that will do one will exactly do the other if the gearing is suitably arranged.

Torque is the product of force × by distance at which it is exerted from center of rotation. If arm D is 3 ft., and 30 lbs. pull is shown at F, at 1500 r. p. m., then the torque would be 30 lbs. × 3 = 90 foot pounds torque.

To find the h. p. at, say, 1500 r. p. m., we start up the engine (having first rigged up to some convenient part a speed counter), open throttle fully, tighten down clamp by the screws (E) until engine is slowed to the required speed namely, 1500 r. p. m. The number of pounds pull on arm (D) is now read off at (F).

Observe now the calculation. We first measure the distance from the central point of the flywheel to the point of the arm which rests on the scale. Assume this to be 3 ft., and the number of lbs. indicated on the scale to be 30, and we have all the necessary information.

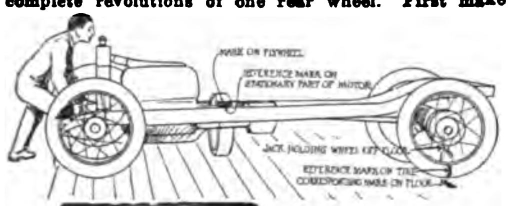
This 3 ft. arm (D) is virtually the radius of an imaginary flywheel 6 ft. in diameter, which exerts at its rim—i. e., at the point resting on the scale—a pull of 30 lbs.

Now a flywheel having a diameter of 6 ft. has, roughly, a circumference of 19 ft., and if its speed is to be 1500 r. p. m., we have here a rim speed of 28500 ft. per minute, exerting a pull of 30 lb., or, in other words, 855000 ft. lbs. per minute. But, as we have seen, 33,000 ft. lbs. per minute is 1 h. p., therefore it requires but a simple division (855,000 ÷ 33,000) to find that the engine is developing nearly 26 h. p.

In actual practice, rather more elaboration is necessary to cope with secondary considerations. A suitable method of dealing with the friction on the flywheel, for instance, must be found. A proper lining for the braking clamp, so that the drag on the flywheel is constant, free from jerks, etc.

Relation of Speed of Engine to Road Wheels.

Fig. 5.—If you did not know the ratio between the speed of the engine and the speed of the car, there is a way of arriving at this ratio approximately. Jack up both the rear wheels as shown in fig. 5, and then after throwing the car into **low gear** crank the engine slowly by hand, counting the number of times the engine has to be completely turned over to one complete revolution of both rear wheels or two complete revolutions of one rear wheel. **First make a reference mark on the flywheel,** or take one of the timing marks as a reference, and after bringing this directly under the pointer, if there is one; or some other reference point on the flywheel housing, make a mark on the tire and another directly below this on the floor. **Now turn the engine slowly,** and when the rear wheel is again in line with its floor mark, count the number of times the flywheel has turned. If it has taken 20 revolutions of the engine, the ratio is 20 to 1, and so on. **Test intermediate and high gear** in the same manner. See page 22 for meaning of ratio and page 583; ratio of different cars.



How To Read a Taximeter.

Fig. 1.

Fig. 2 — **Taximeter starting with tariff sign showing one fare or passenger.**

Fig. 3 — Taximeter with three or more persons.

A taximeter is used on taxicabs for the purpose of keeping tab on the distance traversed and cost per mile to a passenger.

When car is standing the meter is shown with the vacant sign standing upright and all dials at zero, per fig. 1.

When car starts on a trip with one or two persons, the "Vacant" sign is turned to the right, as shown in fig. 2. The tariff shows a figure 1, which means one fare to be charged. The total fare registers 30c which is the charge for the first one-half mile, and which is made when the vacant sign is first pulled to the right. After the first half-mile charge is recorded, the instrument automatically charges 10c for each additional quarter mile. In case a trunk is carried, the driver turns the knob on the reverse side of the instrument, which causes the trunk charge to be recorded, in the "extra" space, and also adds this amount of extra to the "total fare" already recorded. After the passenger leaves the taxicab and pays the fare, the vacant sign is returned to vertical position and figures again go to zero.

When three or more persons enter a taxicab, the "Vacant" sign is turned to the left as shown in fig. 3. The initial charge of 30c is the charge for the first one-third mile and additional 10c for each additional one-sixth mile (note difference of one fare and double fare charge).

When taxicab is kept waiting, there is a clock mechanism which, when the "Vacant" sign is down and the vehicle standing, a charge of 10c is registered for the first 6 minutes, and a similar charge for each additional 6 minutes of waiting. (Note this may vary in different localities.)

CHART NO. 225—The Prony Brake H. P. Test. Ratio of Speed of Engine to Road Wheels. How To Read a Taximeter.

*Piston Displacements of Four-Cylinder Engines in Cubic Inches.

$D^2 .7854\ SN = P.D$

PISTON DISPLACEMENTS — Cubic Inches — 4-CYL. ENGINES

Piston Displacement.

Piston displacement means the volume of gas displaced during one stroke of piston. For example, when the piston is at top d. c. there is a certain volume in the combustion space above the piston, for example say 10 cubic inches. When piston is at bottom of stroke there is a greater volume above the piston, say 63 cubic inches. The piston displacement in this case would be 53 cubic inches for one cylinder or 53×4=212 cu. in. displacement for a 4 cyl. engine.

How to find piston displacement—the formula would be designated thus: D^2 x .7854 x S x N = piston displacement. D^2 means diameter or bore squared or multiplied by itself as 5 x 5. This result is then multiplied by the constant .7854 (the area of a cylinder 1 inch in diameter), this result by (S) the stroke in inches and this result by (N) the number of cylinders.

Example: What is the piston displacement of four cylinders, four inch bore and 5½ inch stroke? Procedure—4 x 4 = 16 x .7854 = 12.566 x 5½ (or 5.5) = 69.115 x 4 = 276.5 cubic inches.

Example: What is the piston displacement of four cylinders, 3⅛ inch bore and 4⅝ inch stroke? Procedure—3⅛ x 3⅛ x .7854 x 4⅝ x 4 = 141.9 cubic inch piston displacement.

For larger stroke and bore than given in table, take the dimensions from the table that would be one half of what you want and double it.

McCullough Formula for Finding the Speed of a Car.

Engine speed per minute x diameter in inches of rear wheel x .002975 ÷ ratio.

Ratio of drive, for example is 4 to 1; means engine crank shaft turns four times to one of rear axle. Therefore the figure to be used to divide by, would be four. The same holds good in all speeds, no matter if in first, second, third or fourth speed.

Example; 1000 (rev. of engine) x 30 (di. in in. of wheel) x .002975 divided by 4 (4 to 1 ratio) equals 22.31 plus, miles per hour.

CHART NO. 226—Piston Displacements (from Automobile Trade Journal). **How to Find Speed of a Car.** *For 8 cyl. engines multiply given displacement by 2. **For 12 cyl. engines multiply by 2.

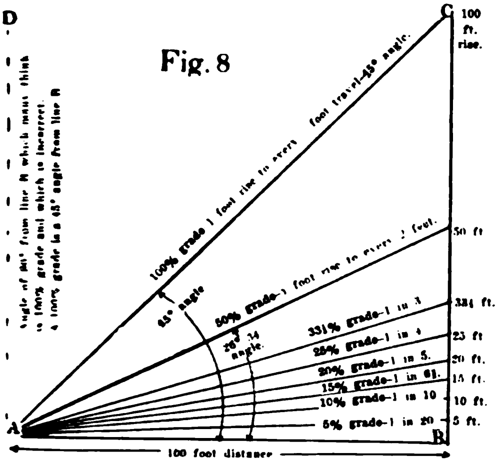
Grades.

The general assumption is that a grade of 100 per cent. would be vertical or 90 degree angle as per line D, which is incorrect.

A grade is expressed in terms of percentage and means so many feet rise or fall in a given distance measured in a horizontal direction. This given distance may, for convenience, be 100, 500, 1000 feet, etc.

A rise of 100 feet in the same distance measured horizontally is a 100 per cent. grade; however, the included angle is 45 degrees and not 90°. Fig. 8 shows the grade percentage, which is based on a horizontal distance (line B) of 100 feet.

Assume that line B is a straight line 100 feet long and perfectly level, therefore from A to B there would be no grade. If from A to B there was a rise of 1 foot in every 20 feet, when we reached line B, we would be 5 feet higher than at A, therefore this would be a 5 per cent. grade. It is not necessary however to travel the full distance, just so long as there is a rise of 1 foot to every 20 feet, it is a 5 per cent. grade at any point.



If the grade or steepness increased to 1 foot rise in 10 feet, then it would be a 10 per cent grade and we would be 10 feet higher at line B than at A; 1 in 6⅔ is a 1 foot rise in 6⅔ feet, and a 15 per cent grade, and so on up to 100 per cent grade, which would be a rise of 1 foot in 1 foot, as from A to C would represent the distance from A to B, or 100 feet, but in reality it is a greater distance, as we would not only travel the distance from A to B but we must also travel included angle of 45 degrees.

To ascertain the percentage of a grade without the use of any special instruments: secure a spirit level and a ten-foot stick. Rest one end of stick on the road surface and find its level position with spirit level, by placing this on the stick and raising or lowering the stick until bubble is in center.

Then measure the perpendicular distance between end of stick and road surface and multiply by 10, which will give the rise in feet in proportion to one hundred feet.

For example, the perpendicular distance measured 18 inches; this multiplied by 10 gives 180 inches, and reduced to feet gives 15 feet as the rise in one hundred feet or 15 per cent grade.

The average of such measurements taken on grades will give fairly accurate results.

Per Cent		Angle
100	1′ in 1′	45°
50	1′ in 2′	26° 34′
25	1′ in 4′	14° 2′
20	1′ in 5′	11° 19′
15	1′ in 6⅔′	8° 37′
10	1′ in 10′	5° 48′
5	1′ in 20′	2° 52′

The affix to figures in center column, as 1′, means 1 foot; whereas in right hand column, as 34′, it means 34 minutes—see pages 93 and 541 for meaning of degrees and minutes.

A 66⅔ per cent grade is as steep as a car could possibly climb, as gravity overcomes traction at this angle.

Miscellaneous Tables.

To convert metres to yards, multiply by 70 and divide by 64.

To convert kilometres to miles, multiply by 5 and divide by 8 (approx.)

To convert litres to pints, multiply by 88 and divide by 50.

To convert grams to ounces, multiply by 567 and divide by 20.

To convert inches to centimetres, multiply by 2.54.

To convert cubic inches to cubic centimetres, multiply by 6.39.

To convert cubic metres to cubic feet, multiply by 35.32.

To convert gallons of water to lbs., multiply by 10.

To find the cubical contents of an engine cylinder, square the diameter (or bore) multiply by .7854 and multiply the result by the stroke.

Atmospheric pressure equals 14.7 lbs. per square inch at sea level.

To find circumference of a circle multiply diameter by 3.1416.

To find diameter of a circle multiply circumference by .31831.

To find area of a circle multiply square of diameter by .7854.

To find area of a triangle multiply base by ½ perpendicular height.

To find surface of a ball multiply square of diameter by 3.1416.

To find solidity of a sphere, multiply cube of diameter by .5236.

To find cubic inches in a ball multiply cube of diameter by .5236.

Doubling the diameter of a pipe increases its capacity four times.

A cubic foot of water contains 7½ gallons, 1.728 cubic ins., and weighs 62½ pounds.

CHART NO. 226-A—How to Find Grade. Miscellaneous Tables. Melting Point of Metals. (See chart 236-A for Metric size Tires into inches.)

See page 585 and index for freezing point, boiling point and specific gravity of water, alcohol, gasoline and kerosene, also freezing and boiling point of mercury. See page 585 for quantity of gasoline to a lb.

Fig. 9. Table: gives the piston travel in feet per minute of engines with different strokes with various crank-shaft speeds. Example: How many feet would a piston travel in an engine with a 3 inch stroke when crank-shaft was turning 200 rev. per min. (r.p.m.)? Ans.: The piston goes down 3 inches and up 3 inches to one rev. of crank-shaft, therefore 3 inches down and 3 inches up would be 6 inches of travel of piston to one rev. of crank-shaft. To 200 rev. of crank-shaft, piston would travel 200×6=1200 inches. If there are 12 inches to a foot, then we would have 1200÷12=100 feet of piston travel per min. to 200 rev. of crank-shaft.

This formula would be: $P = \frac{S \times 2 \times R}{12}$. P, is piston travel per min. which equals, the stroke S, x2, xR (the rev. per min. crank-shaft) divided by 12.

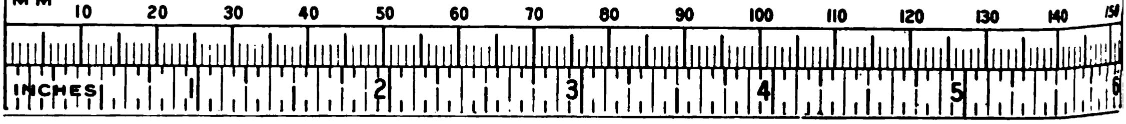

CHART NO. 227—Miscellaneous Tables. The scale rule at bottom of this page is exact size and shows comparative difference between millimeters and inches. *See page 554 for metric sizes of tires.

Degrees, Thousandths of an Inch, Millimeters, Etc.

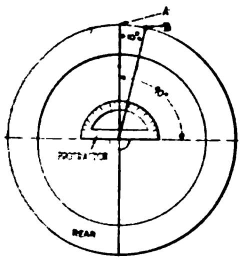
Degrees.

A degree is a unit employed in measuring angles and is the ninetieth part of a right angle or one three-hundred and sixtieth part of a circle.

The degree explanation is given on page 93. See also pages 115 and 314, "converting degrees into inches.

The thousandth part of an inch is referred to quite often in this book, therefore a simple method of finding the measurement is given below. Also see foot note.

Hundredths of an inch to sixty-fourths of an inch is given on page 115.



The metric system—called the French standard, is used quite extensively abroad and is also referred to quite often in this book. Therefore a conversion of those figures most generally used is given, see charts 226A, 227, 236A.

††A protractor is used for dividing circles into any number of equal parts or degrees and determining angles.

For instance, to find the number of degrees in a circle with a protractor; say a fly wheel of an engine. Place protractor as shown. From the center line (A) to (B) is 10°; from (A) to the extreme right, lower part of protractor—if a line was drawn—you would have a right angle or 90°. The number of degrees from extreme left to extreme right of protractor would be 180°, or half a circle. The entire circle would be 360°. In other words the circle is divided into 360 equal parts called degrees and designated with a small "o."

We can divide each degree into 60 parts called "minutes," and each minute can be divided into 60 parts called "seconds." One minute would be designated thus (1′) and one second thus (1″).

Signs or Symbols of Inches, Feet, Minutes and Seconds.

The sign for inches or seconds is (″) as 6″.
The sign for feet or minutes is (′) as 6′.

*Thousandths Part of an Inch.

.001 (one thousandth) = 1/3 thickness of this sheet of paper or about the thickness of fine tissue paper.

.003 (three thousandths) = thickness of this page you are reading.†

.006 (six thousandths) = thickness of two sheets of this paper.

.015 (fifteen thousandths) = thickness of five sheets of this paper.

.020 (twenty thousandths) = thickness of seven sheets of this paper.

.025 (twenty-five thousandths) = thickness of eight and one-third sheets.

.030 (thirty thousandths) = thickness of ten sheets.

‡Decimal Equivalent of Fractional Parts of an Inch.

In using this table it is not necessary to carry out all of the fraction. As a rule, three figures to right of decimal point is close enough for all practical purposes—which would be, of course, read in thousandths, as .015 (fifteen thousandths).

8ths	5/32 = .15625	17/64 = .265625
1/8 = .125	7/32 = .21875	19/64 = .296875
1/4 = .250	9/32 = .28125	21/64 = .328125
3/8 = .375	11/32 = .34375	23/64 = .359375

5/8 = .625	15/32 = .46875	27/64 = .421875
3/4 = .750	17/32 = .53125	29/64 = .453125
7/8 = .875	19/32 = .59375	31/64 = .484375
	21/32 = .65625	33/64 = .515625
16ths	23/32 = .71875	35/64 = .546875
1/16 = .0625	25/32 = .78125	37/64 = .578125
3/16 = .1875	27/32 = .84375	39/64 = .609375
5/16 = .3125	29/32 = .90625	41/64 = .640625
7/16 = .4375	31/32 = .96875	43/64 = .671875
9/16 = .5625		45/64 = .703125
11/16 = .6875	**64ths**	47/64 = .734375
13/16 = .8125	1/64 = .015625	49/64 = .765625
15/16 = .9375	3/64 = .046875	51/64 = .796875
	5/64 = .078125	53/64 = .828125
32ds	7/64 = .109375	55/64 = .859375
1/32 = .03125	9/64 = .140625	57/64 = .890625
3/32 = .09375	11/64 = .171875	59/64 = .921875
	13/64 = .203125	61/64 = .953125
	15/64 = .234375	63/64 = .984375

.015 is approximately 1/64″; .025 is 1/40″.

Millimeters to Inches.

m—is the designation of meter; cm—centimeter; m m or m/m—milli-meter.

1 millimetre is approximately 1/25 inch and is exactly .03937 inch.

1 centimetre is approximately 13/32 inch and is exactly .3937 inch.

1 metre is approximately 39 1/4 inches and is exactly 39.37 inches, or 1.0936 yards.

1 kilometre is approximately 5/8 mile and is exactly .6213 mile.

1 kilogramme is approximately 2 1/4 lbs. and is exactly 2.21 lbs.

1 litre is approximately 1 3/4 pints and is exactly 1.76 pints.

10 mm.	=	1 Centimeter	=	0.3937	inches.
10 cm.	=	1 Decimeter	=	3.937	inches.
10 dm.	=	1 Meter	=	39.37	inches.

25.4 mm. = 1 English inch.

¶Inches piston travels. †Before. ‡After.

Valve Timing of Engines on Leading 1919 Cars.

The table to the left gives the valve setting in degrees and minutes. For instance, the intake closes 46-40 on the Cadillac, meaning 46 degrees and 40 minutes. See pages 541 and 93 for meaning of degrees and minutes.

The table also gives the *valve clearance and also the diameter and length of the valve, as taken from Motor Age.

Average Valve Setting.

If the timing of an engine is not known and you desire to set the valves, here is a plan to follow.

The pitch of the timing gears is generally coarse enough to allow of only one proper setting and when the proper position is almost reached the tooth of the cam shaft gear which should mesh between the two teeth on the crankshaft gear, will be so close that less than the width of one tooth will be between that and exact position

The following is an average setting of 114 cars as given by Motor Age. Intake opens 9.5 degrees late and closes 37 degrees late. The exhaust valve opens 50 degrees before bottom and closes 9 deg. late. It is not necessary to pay any attention to more than one of these dimensions, for instance, set the exhaust closing with cam shaft, as most engines are L type with all cams on one shaft.

After making this setting you can determine if the setting is wrong, as it will probably be out only one tooth on the camshaft gear one way or the other.

Capacity of Cylindrical Tanks.

The table gives the capacity of tanks in gallons for given sizes.

Length	12 in.	16 in.	20 in.	24 in.	28 in.	32 in.	36 in.
Diameter	Gal.	Gal.	Gal.	Gal.	Gal.	Gal.	Gal.
10 in.	4.09	5.45	6.81	8.17	9.53	10.89	12.25
15 in.	9.20	12.27	15.34	18.40	21.47	24.54	27.61
20 in.	16.36	21.80	27.24	32.68	38.12	43.56.	49.00
25 in.	25.56	34.08	42.60	51.12	59.64	68.16	76.68
30 in.	36.81	49.05	61.29	73.53	85.77	98.01	110.25
35 in.	50.15	66.87	83.59	100.31	117.02	133.74	150.46

Formula for computing the capacity of a cylindrical tank is as follows:

$$C = \frac{D^2 \times L}{293.3}$$

C, is the capacity in gallons.
D, is the diameter of tank in inches.
L, is the length.

Example: What is the capacity of a tank 10" dia. and 12" long?

C is the capacity of the tank which we desire to know, and is equal to the diameter squared (D^2) or mutiplied by itself, as $10 \times 10 = 100$ × by (L) the length, or 12 inches = 1200. The line under $D^2 \times L$ means that the total of $D^2 \times L$, which is 1200, is divided by a constant 293.3 = 4.09 gallons.

CHART NO. 228—Standard Adjustments. Valve Timing of Leading 1919 Cars. Average Valve Clearance. Capacity of Tanks. For Gear Shift Movements—see page 490.

*See also, page 635 for average valve clearance

T—Means to place piston at top of stroke.

R—Means interrupter is retarded.

If an automatic advance the setting must be accurate.

After placing piston on top and retarding the timer housing, the interrupter points should just be opening, if a "closed circuit" type of timer, or just closing if an "open circuit" type timer. It is difficult to see this, therefore a good plan is to use a 6 volt lamp in the low tension circuit (between battery and timer). In this way one can tell when circuit is closed or opened at timer points, by the light going out or on (similar to fig. 70, page 729). See pages 250, 254, 378, for Atwater-Kent, Connecticut and Delco timing instructions.

The above timing is an average timing to be followed in absence of no definite instructions from manufacturer.

**—NU4 Bosch spark plug gap is .016".

† —4, 6, 8 and 12 cyl. engines spark plug gap is .025" and 8 cyl. engines .020". On 4, 6 and 8 cyl. engines place piston 1/16" before top with interrupter retarded. On 12 cyl. engines place piston on top and int. retarded.

††—Eisemann new style spring contact breaker .012", others .016".

CHART NO. 232—Specifications of Leading 1920 Cars. See page 543 for Abbreviations.

See page 545 for headings to these columns.

Orphan Cars.

Parts for Cars No Longer Manufactured—Where to Obtain the Parts.

A

- **Abbott** — Consolidated Car Co., Detroit; Puritan Machine Co., Detroit; Jos. C. Gorey & Co., New York; Abbott-Detroit Parts Corp., New York
- **Acme** — Puritan Mach. Co., Detroit
- **Aerocar** — Auto Parts Co., Chicago; Puritan Machine Co., Detroit
- **Alco** — International Motor Co., New York; Puritan Mach. Co., Detroit; Jos. C. Gorey & Co., New York; American Locomotive Co., Providence, R. I.; Alco Service Co., Philadelphia; Rand & Chandler, Los Angeles, Cal.
- **Alden-Sampson** — Standard Motor Parts Co., New Castle, Ind
- **Allen-Kingston** — New Departure Co., Bristol, Conn.
- **Allis-Chalmers** — Puritan Machine Co., Detroit
- **Alpena** — Puritan Machine Co., Detroit
- **American** — Levens Motor Co., Philadelphia, Pa; American Motor Parts Co., Indianapolis; V. A. Longaker Co., Indianapolis; Jos. C. Gorey & Co., New York; Puritan Mach. Co., Detroit; Burt Motor Car Co., Los Angeles, Cal.
- **American Mors** — St. Louis Car Co., St. Louis
- **American Truck** — Auto Parts Co., Chicago
- **Amplex** — Gillette Motors Co., Mishawaka, Ind.
- **Anchor** — Anchor Buggy Co., Cincinnati
- **Anhut** — Puritan Machine Co., Detroit; Auto Parts Co., Chicago
- **Ardsley** — Ardsley Motor Car Co., Yonkers, N. Y.
- **Argo** — Puritan Mach. Co., Detroit
- **Atlantic** — Puritan Machine Co., Detroit
- **Atlas** — Auto Parts & Repair Co., Springfield, Mass.; Puritan Machine Co., Detroit; Jos. C. Gorey, New York City
- **Autocar** — Autocar Co., Ardmore, Pa.

B

- **Babcock** — Babcock Mfrs. Supply Co., Watertown, N. Y.; Puritan Machine Co., Detroit
- **Badger** — Schultz & Harder, Columbus, Wis.; Puritan Machine Co., Detroit
- **Barnes** — Auto Parts Mfg. Co., Detroit; Puritan Machine Co., Detroit
- **Benham** — Puritan Mach. Co., Detroit
- **Bergdoll** — Louis J. Bergdoll Co., Philadelphia; Levens Motor Co., Philadelphia; Jos. C. Gorey, New York City
- **Berkshire** — E. B. Belcher, Cambridge, Mass.; Berkshire Motor Co., Pittsfield, Mass.; Puritan Machine Co., Detroit
- **Berliet** — American Locomotive Co., Providence, R. I.
- **Bessemer** — Robt. M. Cutting Co., Chicago
- **Black Crow** — Black Mfg. Co., Chicago; Crow Motor Car Co., Elkhart, Ind.
- **Blomstrom** — Auto Parts Co., Detroit; Puritan Machine Co., Detroit
- **Borland** — Puritan Machine Co., Detroit
- **Briggs-Detroiter** — Puritan Machine Co., Detroit
- **Brintell** — Puritan Machine Co., Detroit
- **Brownikar** — Hinsdale Electrical S. Co., Hinsdale, Ill
- **Broc Electric** — Puritan Machine Co., Detroit
- **Brodesser** — Puritan Machine Co., Detroit
- **Brush** — Standard Motor Parts Co., Newcastle, Ind.; Puritan Machine Co., Detroit; Davidson Repairshop, 227 West 64th St., New York, N. Y.
- **Buffalo Electric** — Puritan Machine Co., Detroit

C

- **California** — California Auto Co., Los Angeles, Cal.; Puritan Machine Co., Detroit
- **Cameron** — Cameron Mfg. Co., New Haven, Conn.
- **Carhartt** — Auto Parts Co., Chicago; Jos. C. Gorey & Co., New York; Puritan Machine Co., Detroit
- **Carnation** — Carnation Motor Car Co., Detroit; Auto Parts Co., Chicago; Puritan Machine Co., Detroit; K. C. Auto Parts Co., 1827 McGee St., Kansas City, Mo.
- **Cartercar** — Puritan Machine Co., Detroit
- **Carthage** — Puritan Mach. Co., Detroit
- **Cavac** — Puritan Machine Co., Detroit
- **Century** — Puritan Mch. Co., 422 Lafayette Blvd., Detroit
- **Chadwick** — Chadwick Eng. Works, Pottstown, Pa.
- **Chief** — Auto Parts Mfg. Co., Detroit; Chief Motor Co., Detroit
- **Cino** — Haberer & Co., Cincinnati
- **Ciaco** — Puritan Mach. Co., Detroit
- **Clark** — Clark Motor Car Co., Shelbyville, Ind.; Meteor Motor Car Co., Piqua, Ohio; Clark Auto Co., Atlanta, Ga.; Puritan Machine Co., Detroit; American Motors Parts Co., Indianapolis
- **Clark-Carter** — Cutting Motor Car Co., Jackson, Mich.; L. C. Erbes, Waterloo, Iowa; Puritan Machine Co., Detroit; Robt. M. Cutting Co., 2635 S. Wabash Ave., Chicago
- **Cleveland** — Western Motor Car Co., Cleveland, Ohio; Garford Motor Truck Co., Lima, Ohio
- **Coates-Goshen** — Coates-Goshen Auto Co., Goshen, N. Y; Miller Car Co., Goshen, N. Y.
- **Colby** — A. O. Smith, Milwaukee, Wis
- **Colburn** — Colburn Automobile Co., Denver, Col; Erickson & Stalnaker, Denver, Col.; Puritan Mach. Co., Detroit
- **Colley** — Puritan Machine Co., Detroit
- **Columbia** — Columbia Auto Repair Co., Hartford, Conn; Standard Motor Parts Co., Newcastle, Ind
- **Columbus Electric** — New Columbus Buggy Co., Columbus, Ohio
- **Connersville** — Puritan Machine Co., Detroit
- **Continental** — Puritan Mach. Co., Detroit
- **Corbin** — Corbin Motor Vehicle Co., New Britain, Conn.
- **Corbitt** — Puritan Machine Co., Detroit
- **Correja** — J. C. Gorey & Co., New York
- **Courier** — Standard Motor Parts Co., Newcastle, Ind.; Puritan Machine Co., Detroit
- **Courier-Clermont** — Standard Motor Parts Co., Newcastle, Ind.
- **Craig-Toledo** — A. W. Colter, Toledo; Puritan Machine Co., Detroit
- **Crescent** — Northway Auto Parts & Sales Co., Cincinnati; Puritan Machine Co., Detroit
- **Cricket** — Puritan Machine Co., Detroit
- **Crow** — Black Mfg. Co., Chicago; Crow M. C. Co., Elkhart, Ind.; Puritan Mach. Co., Detroit
- **Croxton** — Auto Parts Co., Chicago; Puritan Machine Co., Detroit
- **Croxton-Keeton** — K. C. Auto Parts Co., 1827 McGee St., Kansas City, Mo.
- **Cutting** — Puritan Machine Co., Detroit; Harris Bros. Co., Chicago; S. C. Erbes, St. Paul, Minn.

D

- **Dart** — Puritan Machine Co., Detroit
- **Dayton** — Puritan Machine Co., Detroit
- **Deal** — Auto Parts Co., Chicago
- **Dearborne-Detroit** — Hawn Motor Car Co.
- **De Luxe** — Puritan Machine Co., Detroit
- **De Mot** — Puritan Machine Co., Detroit
- **De Tamble** — American Motors Parts Co., Indianapolis; Puritan Machine Co., Detroit; De Tamble Motors Co., Anderson, Ind.
- **Dragon** — Philadelphia Mch. Wks., Philadelphia
- **Duer** — Chicago Coach & Carriage Co., Chicago
- **Durocar** — Puritan Machine Co., Detroit

E

- **Eclipse** — Kruegar Motor Car Co., Milwaukee; Frank Toepfer's Sons, Milwaukee
- **Edwards** — Edwards Motor Car Co., Long Island City, N. Y.; Puritan Machine Co., Detroit
- **Electric Vehicle** — Maxwell Briscoe Motor Co., L. I. City, N. Y.
- **Elk** — Puritan Machine Co., Detroit
- **Elmore** — Auto Parts Co., Chicago; Jos. C. Gorey & Co., New York; Puritan Machine Co., Detroit; Standard Motor Parts Co., New Castle, Ind.
- **Evertt** — Holt-Chandler, Long Island City, N. Y.
- **Everitt** — Maxwell Motor Sales, Newcastle, Ind.; Jos. C. Gorey & Co., New York; Puritan Machine Co., Detroit
- **Ewing** — Jos. C. Gorey, New York; Puritan Mach. Co., Detroit; L. E. Ewing, Leader Bldg., Cleveland, O.

F

- **F. A. L.** — Puritan Machine Co., Detroit; Auto Parts Co., Chicago; K. C. Motor Parts Co., 1827 McGee St., Kansas City, Mo.
- **Findley** — L. E. Ewing, Cleveland
- **Firestone Columbus** — Puritan Machine Co., Detroit; New Columbus Buggy Co., Columbus, Ohio
- **Flanders** — Puritan Machine Co., Detroit; Studebaker Corp., Detroit
- **Fuller** — Jackson Automobile Co., Jackson, Mich.

G

- **Gaeth** — Gaeth Motor Car Co., Cleveland
- **Garford** — Elyria Belting & Machinery Co., Elyria, Ohio; Garford Motor Truck Co., Lima, Ohio; Puritan Mach. Co., Detroit
- **G. J. G.** — Puritan Machine Co., Detroit
- **Gilde** — Jos. C. Gorey & Co., New York
- **Grabowsky** — Puritan Machine Co., Detroit; Jos. C. Gorey, New York City
- **Gramm** — Garford Motor Truck Co., Lima, Ohio; Puritan Machine Co., Detroit
- **Gleason** — Bauer Mch. Wks. Co., Kansas City, Mo.
- **Great Smith** — Bauer Mch. Wks. Co., Kansas City, Mo.; Smith Automobile Co., Topeka, Kan.
- **Great Western** — Great Western Auto Co., Peru, Ind.
- **Grout** — A. F. Kirkpatrick, Orange, Mass.; Puritan Mach. Co., Detroit

H

- **Halladay** — A. O. Barley, Streator, Ill.; A. O. Smith Co., Milwaukee; W. J. Burt Motor Car Co., Los Angeles
- **Hart-Kraft** — Quincy Engine Co., Chambersburg, Pa.; Petrie & Morganthall, Greencastle, Pa.
- **Havers** — Puritan Machine Co., Detroit; Jos. C. Gorey, New York
- **Henderson** — Henderson Motor Car Co., Detroit; Auto Parts Co., Chicago; Puritan Machine Co., Detroit
- **Henry** — A. O. Smith Co., Milwaukee; Jos. C. Gorey, New York; Puritan Machine Co., Detroit; Muskegon Auto Co., Muskegon, Mich.
- **Herreshoff** — American Motor Parts Co., Indianapolis; Puritan Machine Co., Detroit; Levene Motor Co., Philadelphia; Jos. C. Gorey, New York
- **Hewitt** — International Motor Co., New York
- **Holsman** — Mercury Mfg. Co., Chicago
- **Houpt** — New Departure Mfg. Co., Bristol, Conn.

—from Motor World.

Additions.

Argo Electric, Briggs-Detroiter, Elco, Little Four, Yale Eight, Partin-Palmer, E. M. F-30., Alter, Detroiter 6-45, Standard Det. Tractor Co., Repairs of Weston Mott Axles, Repairs of Am. Ball Bearing Axles prior to 1919. Parts for sale by Puritan Machine Co., Detroit, Mich. This concern will also give you information on other orphan cars not shown in this list. Enger, American Motor Parts Co., Indianapolis, Ind.; Herff Brooks, Auto Salvage Co., Kansas City, Mo.; Dolson, Dayton Auto Parts Co., Dayton, Ohio; Dupont, Victor Motor Co., York, Pa.; E. M. F. Studebaker Corpn., Detroit, Mich.; Austin. Puritan Machine Co., Detroit; Pullman, Pullman Motor Car Co., York, Pa.; Puritan Machine Co., Detroit; Ross. Puritan Machine Co., Detroit.

I

- Imperial — Imperial Automobile Co., Detroit
- Indiana — Puritan Machine Co., Detroit

- Speedwell — Puritan Mach. Co., Detroit; Jos. C. Gorey & Co., New York; Green Engineering Co., Dayton, Ohio
- Springfield — R. Hass Elec. & Mfg. Co., Springfield, Ill.
- Standard Six — St. Louis Car Co., St. Louis, Mo.; Puritan Machine Co., Detroit
- Star — Mier Carriage & Buggy Co., Ligonier, Ind.
- Staver — Puritan Machine Co., Detroit
- Sterling — Keith Brothers, Elkhart, Ind.
- Stevens-Duryea — Walk Hill Garage, 726 Walk Hill St., Matapan, Mass.
- Stoddard-Dayton — Standard Motor Parts Co., Newcastle, Ind.; Puritan Machine Co., Detroit; Dayton Auto Repair Co., New York City
- Suburban — Puritan Machine Co., Detroit
- Sultan — Jos. C. Gorey, New York City

T

- Thomas — E. R. Thomas Motor Car Co., Buffalo, N. Y.; Puritan Machine Co., Detroit; W. H. Jahns, 908 W. Pico St., Los Angeles, Cal; J. Rosenfeld, 521 6th St., South, Boston.
- Tincher — Chicago Coach & Carriage Co., Chicago
- Tourine — Jos. C. Gorey, New York
- Tourist — W. J. Burt Motor Car Co., Los Angeles, Cal
- Traveler — Traveler Automobile Co., Evansville, Ind
- Twombly — Driggs-Seabury Ordnance Co., Sharon, Pa.

V

- Van — L. C. Erbes, Waterloo, Iowa
- Van Dyke — Puritan Mach. Co., Detroit
- Victor-Thomas-Detroit — Puritan Machine Co., Detroit

W

- Wagenhalls — Riverside Machinery Depot, Detroit
- Wahl — Harris Bros. Co., Chicago; Barley Mfg. Co., Streator, Ill.; Puritan Machine Co., Detroit
- Waltham-Orient — Metz Co., Waltham, Mass.
- Warren — Jos. C. Gorey & Co., New York; Puritan Machine Co., Detroit
- Washington — Puritan Machine Co., Detroit
- Waverley Electric — V. A. Longaker Co., Indianapolis
- Wayne — Auto Parts Mfg. Co., Detroit; Puritan Machine Co., Detroit
- Welch-Detroit — Puritan Machine Co., Detroit
- Welch-Marquette — Oldsmobile Co., Chicago, Ill.
- Welch-Pontiac — Puritan Machine Co., Detroit
- Whiting — Chevrolet Motor Co. of Mich., W. Kearsley St., Flint, Mich.; Puritan Machine Co., Detroit
- Woodworth — Puritan Machine Co., Detroit

Y

- Yale — Consolidated Mfg. Co., Toledo, Ohio

Z

- Zip — H. A. Huebotter, Davenport, Iowa

To find addresses of Ignition, Magneto, Electric System Manufacturers, also Auto Trade Publications, etc.—look under "Addresses" in the index.

**TIRES: Pneumatic. Rims. Air Compressors. Anti-Skid Chains. Solid Tires. Truck Tires for Heavy Duty.

Tires are used on automobiles to overcome the vibration. If the wheels of an automobile were not properly tired, the machine would soon rack itself to pieces. The great weight and speed of the automobile and its delicate construction, require additional protection besides that of the springs alone.

There are two types of tires, the solid and the pneumatic. The **solid tire is used** to a great extent on electric vehicles and trucks, because they are usually **slow speed** vehicles. If solid tires were used on **high** speed cars the vibration would be **so great** the car would soon rack itself **to pieces.**

The Pneumatic Tire.

The pneumatic tire is the type used on all pleasure cars. With pneumatic tires, the car is suspended in air, which is the most elastic of substances.

There are two methods of retaining the air, the first and now obsolete method, was a single tube tire, made air tight and did not use an inner tube.

There are two forms of pneumatic tires; the single and the double tube. The single tube tire was merely an outer casing made air tight and was fitted with an air valve. This type was used extensively during the early days of motoring, but inasmuch as it is now obsolete, we will confine our instruction mainly to the modern type.

The modern automobile pneumatic tire consists of two chief parts, the "inner tube," which holds the air, and the "shoe or casing," which retains the inner tube, and protects it from wear. (fig. 2, page 550.)

A steel rim is placed around the felloe of the wheel, and shaped to fit the tire, its exact shape depending on the design of the tire. The clincher and straight side rim are the styles universally used.

Double tube tires have projections on the side called beads, which fit under grooves or into channels in the side of the rim, the pressure of the air in the inner tube holding them in place. See figs. 8, 8A and 9, page 552.

*Bolts, or **lugs**, also sometimes called **stay bolts** or security bolts (fig. 2) pass through the felloe and rim, their large rubber or canvas-covered **heads** holding the extreme inner edges of the shoe against the rim. Lugs are now seldom used.

Tread, is the part of an outer shoe or casing, which is the part that comes in contact with the road. **Bead,** is the projection at the edges that fit into the rim.

Outer cases, also called the outer shoe are divided into two classes; the "fabric" type and the "cord" type as explained on pages 565 and 559. **The strength of the tire lies in this fabric or cord carcass, the cushion and protection for the carcass of the tire is in the rubber.** Sea Island cotton which is very strong, is used for the **carcass** of the fabric tire and cords are used for the carcass of the cord tire.

Inner Tube and Valve.

Inner tubes used on automobile pneumatic tires are of the endless type. The only opening into the tube is the valve, through which the air is forced, fig. 6, page 550. As tube becomes inflated by air pumped into it, the bead of tire is forced outward and tightly clinches to the rim channel and can only be dislodged by deflating tube.

†**The inner tube valve-stem** is the part shown in fig. 6, page 550. It is the part to which the inner tube is connected as shown in fig. 5. (T) is the inner tube. The base, (G) of the valve stem is passed through a heavy, tough piece of rubber, called the "valve-stem-seat" which is vulcanized to the tube as shown in fig. 6, page 572. By stretching the opening in this valve stem seat, the base (G) is placed inside of tube and firmly locked by clamp nut (ST), figs. 5 and 6, page 550.

The inner-valve A, fig. 6A, also called the "valve plunger," is an automatic air check valve for retaining the air in the tube. It is screwed into valve stem opening, usually by the notched end of (B) the valve cap (see fig. 2, page 568). V is the threaded part which screws into valve stem. W, is metal with rubber packing (D) around it, which makes an air-tight joint with walls of valve-stem. Y is cap holding spring (S) in place, and on upper part is a rubber washer which is the "valve-seat" which is between bottom of (W) and upper part of (Y). This is the seat, or point where air pressure in tube is retained because the lower part of (W) is in contact with rubber washer seat on top of Y, which is held together by tension of spring. This seat is shown open in illustration. Pin (U) is firmly attached to Y but works freely through enlarged holes in V and W, which hole also serves as the air passage to or from valve seat. The spring holds the valve to its seat but can be depressed at (U) or air from air pump will be sufficient to force valve from its seat.

To inflate tube, unscrew valve cap (B) and screw in its place the hose coupling from air line. Inside of this hose coupling is a projection which presses the pin (U) down against tension of spring (S) which separates the seat on upper part of Y from lower part of W—the air then passes in through enlarged hole in V and W and out bottom of W at seat, which is now open. When air-line coupling is removed pin U raises and brings upper part of Y and bottom part of W to a firm seat, and pressure of air in tube also assists in forcing spring S against Y and tightening the seat.

To deflate tube, valve cap B is removed, turned upside down (per fig. 2, page 558) and pin U (fig. 6A, page 550) is pressed down by it, which opens inner-valve seat. Or, the valve cap B can be used to unscrew inner valve at V and removed entirely, which is the proper thing to do when removing a punctured tube or rolling it up, per fig. 7, page 568.

Sometimes the inner-valve leaks, due to the valve cap (B) being screwed down so tight the rubber disc (C) spreads and forces pin (U) down.

*Lugs are now seldom used but were formerly used on "one piece clincher" rims to a great extent.
**See Specifications of Leading Cars, pages 544 to 546, for make and size tires used on leading cars.
†Valve stem is passed through hole in felloe of wheel—see page 558, fig. 2A. Stem is held in place by lock nut (N) and washer (M), fig. 6, page 550. See page 571 for purpose of the spreader.

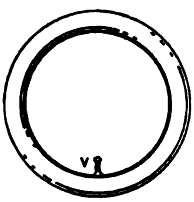

Fig. 1—The old style and original pneumatic tire was a "single tube tire." The casing itself held the air and did not contain an inner tube.

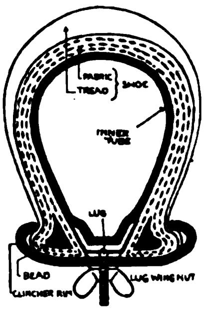

Fig. 2—The old style double tube clincher bead tire on a one piece clincher rim. Note the lug formerly used to hold tire on the rim. Pneumatic tires were called "double tube" tires in the early days to distinguish them from the single tube tire, fig. 1.

The clincher tire can be applied to a quick detachable clincher rim.

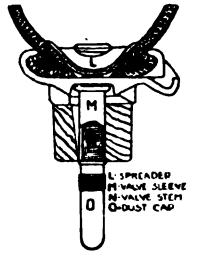

Fig. 3 — A quick detachable demountable "clincher" rim.

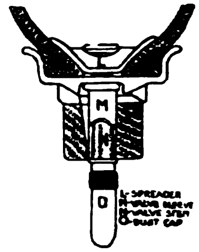

Fig. 4—A quick detachable, demountable, straight side rim.

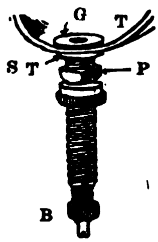

Fig. 5 — All pneumatic tires now contain inner tubes. Note method of clamping the air valve to inner tube. Inner tubes are endless and seamless.

T, tube; G. base; ST, clamp nut; P, lock-nut.

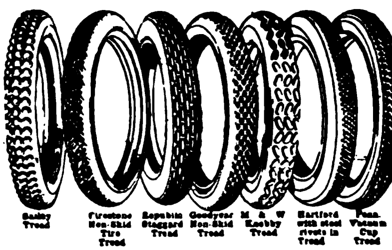

Fig. 9—Types of non-skid tires.

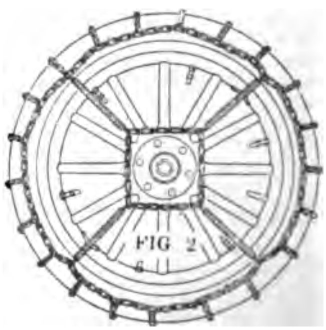

***Fig. 10—Non-skid chains.** For snow, ice, mud and skidding. The chains are placed over the tires. See chart 236-F for grip or chain for solid tires. The chain is a sure preventive of slipping and skidding.

CHART NO. 235—Tires—Original and Modern Types. Inner Tube Valve Construction.

Charts 233 and 234 omitted by error in numbering. *See also, page 560.

Slow Air Leaks.

Slow air leaks from tube are sometimes traced to this "inner-valve" A, leaking.

†**To test for inner-valve leak,** inflate tube and test, per fig. 3, page 568. If leaky, try cleaning and screwing down tight, if this does not remedy leak, then put in a new "inner-valve." A slow leak may also be due to valve-stem base (G) being loose—or inner tube rubber being porous, due to age which in time hardens, becomes porous and leaks slowly. **To test for valve stem or slow leak or puncture;** see fig. 4, page 568. **The average life of a tube is from twelve to eighteen months, maybe two years—but once it begins to harden—it is advisable to replace with new tubes.**

The purpose of the spreader (L), fig. 6, page 550 is explained on page 571.

Treads of Tires.

The treads of tires or outer casings are divided into three types; the smooth tread, as shown in fig. 7, and the **non-skid tread** (fig. 8) and the **ribbed tread,** fig. 8A, page 550. There are several different makes of non-skid treads, (as shown in fig. 9) but the principle or purpose of all are to prevent skidding. The original non-skid tire was the Bailey tread. The Firestone non-skid tread was the second tire of this type introduced.

The number of accidents which have occurred on account of skidding on slippery pavements, has shown the need for some method of prevention.

****The original method was by the use of tire chains** (fig. 10), which, so far as the prevention of skidding was concerned, fulfilled their purpose. But the use of chains was found to be detrimental to tires when introduced between the blown-up tire and hard pavement, and in addition were hard riding and noisy.

The non-skid tread was introduced to overcome this difficulty, but while they prevent skidding to a great extent, it still seems as though the chain is the best preventive of skidding after all. The extra wear and gripping surface obtained with the non-skid tread is well worth the difference in price, and ought to at least be placed on the rear wheels.

The modern tire equipment consists of smooth or ribbed tires for the front wheels and non-skid tread tires for the rear wheels, with rims of the demountable straight side type.

Leather cover protection for tires: In fig. 5, page 559, we illustrate a tire protector called the Woodworth Leather Tread. This cover is made of leather with steel rivets which pass through the tread. The covers are made to fit over the tire. They protect the tire from wear and from punctures, cuts and bruises, or other outside injuries, but are not suitable for high speed cars.

‡Rims and Tire Beads.

Beads of tires: There are three beads. (1) "Plain clincher" bead fig. 2, page 550, which is **flexible** and intended for one-piece clincher rims. (2) Clincher bead tire with a **hard** bead for use on "quick detachable" rims as fig. 3, page 550. (3) "straight side" bead for use on rims with a straight side as per fig. 4, page 550.

Rims are made with projections on the side to take either the "clincher" or "straight side" bead tire.

Clincher rims can be either a 'one-piece clincher rim" as per fig. 2, page 550, or it can be a "quick detachable rim" where one side of rim is removable as per fig. 3, page 550.

To attach or detach a tire on a one-piece clincher rim it is necessary to raise the beads of the tire over the rims as per figs. 1 to 8, page 558, and that is why the bead is made flexible.

To atach or detach a clincher bead tire on a quick detachable rim it is only necessary to remove the "locking ring" and "clincher side ring" per fig. 1, page 555 and the tire can be slipped on or off without much stretching, therefore it is not necessary to have a flexible bead.

Therefore a flexible bead clincher tire can be fitted to either a "one-piece clincher rim" or a "quick detachable clincher rim," but it would be a difficult matter to stretch a **hard** bead clincher tire over a "one-piece clincher rim."

Straight-side rims to take straight-side bead tires can be "one-piece" rims as per type "E," page 555, but it must be "demountable" and "split.':' That is, the rim can be removed from the wheel by removing bolts on the side, then rim with tire on it is removed from wheel and rim which is split, is then removed from the tire, as shown in figs. 4 and 5, page 556 and fig. 2, and 1 to 10, page 557. The type E rim is very popular.

Straight side rims to take straight side bead tires can also be "quick-detachable" type of rims as per type "C," page 555. Note with this rim the tire can be removed from rim while on wheel, by removing a side ring as per figs. 1 to 3, page 556 and fig. 12, page 557. Or the rim with the tire can be demounted from wheel with tire on it and tire removed from rim as explained on page 556, figs. 1 to 3.

The universal rim is the type of rim which was formerly used to a great extent. This rim is shown in type B, page 555 and was reversible. By having the rings (B) as now shown in illustration, the rim would take a "straight-side bead" tire. By **reversing** this ring as per fig. 2, page 552, the rim would take a "clincher bead" tire.

Demountable rims are those rims which are not permanently fastened to the wheel and can be removed with tire, usually by loosening bolts on the side as shown on page 556. See also type A, B, C and E rims, page 555, all of which are demountable.

—continued on page 553.

****For heavy weather and snow time there is nothing equal to a good set of chains; one on each wheel.** If only two are used they should be on the **rear** wheels. If only one, it should be on the left rear, to avoid being damaged against the curb. Fasten them tightly, but not so tightly that they cannot creep. If they are held rigidly in one place they wear into the tread and ruin it (see pages 550, 559).

‡**The straight side rim is the popular rim.**

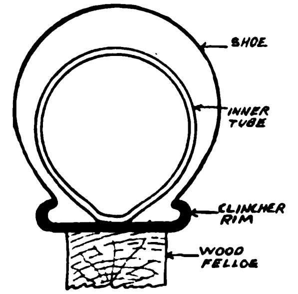

Fig. 1—Clincher tire on a one piece clincher rim.

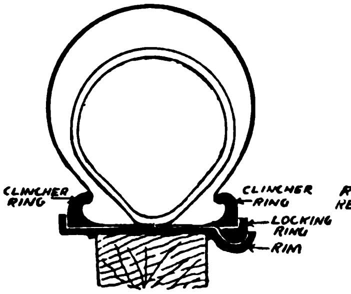

Fig. 2—Clincher tire on a quick detachable rim.

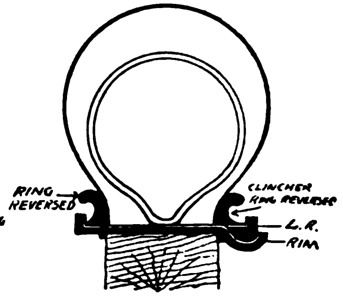

Fig. 3—Straight side tire on a quick detachable rim where the clincher part of rim is reversible—universal rim.

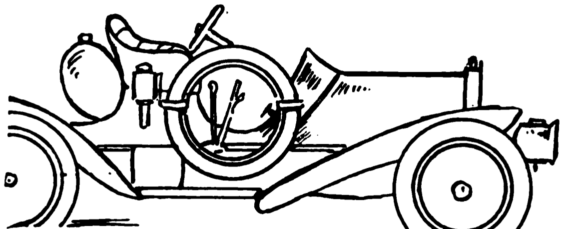

Fig. 5—Showing a tire inflated on a demountable rim, carried on the side of the car or the rear, ready to put in the place of a damaged tire. Note, this tire is inflated.

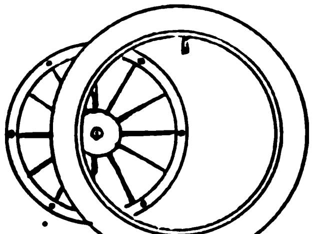

Fig. 4—A tire on a demountable rim. Note the inner part of rim is permanently attached to felloe of wheel. This tire is usually carried on rear of car inflated, on a spare rim. The damaged tire is removed and the inflated tire and rim is slipped over the wheel rim. The straight side or clincher tire can be demountable.

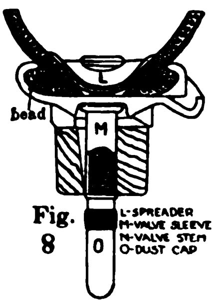

Fig. 8

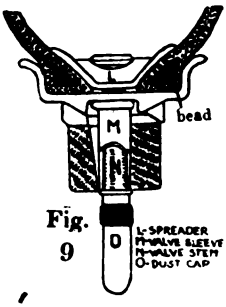

Fig. 9

Types of Tire Beads.

Fig. 8—A clincher hard, non-stretchable bead tire on a quick detachable, demountable rim.

Fig. 8A—A clincher flexible bead tire is practically the same tire except bead is flexible and is used on the "one-piece" clincher rim fig. 1. (Fg. 8A not illustrated.)

Fig. 9—A straight side bead tire on a straight side, demountable rim.

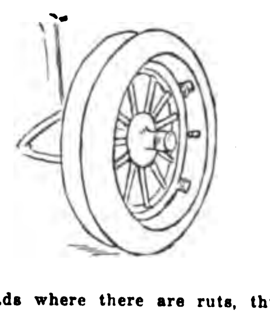

Fig. 7 — Spare emergency tire and rim is a type of tire usually carried inflated on a special rim which can be bolted or clamped to the side of the damaged tire. The damaged tire is not removed until destination is reached. This principle is seldom used. Disadvantage is that the wheels do not track properly and on country roads where there are ruts, this is serious.

A straight side bead tire with a non-skid tread. Can be either the "fabric" or "cord" type of carcass, as explained on page 565.

Fig. 8—Quick detachable clincher cases have non-stretchable beads and can only be used on quick detachable clincher rims and the split type clincher rims. This style of tire should always be equipped with flaps.

Fig. 8A—Regular clincher cases have stretchable or flexible beads and are designed for use on regular clincher (one piece) rims; they are sometimes used also on quick detachable clincher rims. When used on regular clincher rims, it is desirable for sizes including the 4 inch and above, to use clips or stay bolts to hold beads securely in rim clinches. **When using regular clincher tires on quick detachable clincher rims,** it is necessary to use flaps to protect the inner tubes.

Fig. 9—Straight side or straight bead cases have non-stretchable cables imbedded in the base and are designed only for quick detachable straight side rims and split type of straight side rims. **This style should always be equipped with flaps. Straight side tires are sometimes used on quick detachable clincher rims having fillerbeads fitted in clinches of rims. This is not to be recommended, however, as the base width of this style of rim is not suitable for straight side tires.**

CHART NO 236—Rims: One piece Clincher. Quick Detachable Clincher, Quick Detachable Demountable Clincher, Reversible Q. D. Rims. Straight Side Type. The Emergency Tire.

—continued from page 551.

A straight-side bead tire can be used on a "quick detachable clincher rim" but a "filler bead" should be used to protect the bead from cutting. A straight side bead tire cannot be used, however on a "one-piece clincher rim." A clincher bead tire cannot be used on a straight-side rim.

Spare Tires.

A spare tire inflated, on a spare "demountable" rim, which can be a "clincher," "quick detachable" or "one-piece" rim, can be carried on rear or side of car as per fig. 5, page 552. This rim can be placed over wheel when damaged tire with rim is removed.

A spare wheel with inflated tire can also be carried on car ready to place on wheel spindle when damaged tire with wheel is removed. This is quite popular with wire and disk wheels.

A spare emergency tire with inflated tire can also be carried on car, which can be bolted to side of damaged tire as per fig. 7, page 552, but this method has disadvantages as explained on page 552, fig. 7.

The straight side bead tire is now the popular type of bead, in fact the clincher tire is now made only in sizes of 30x3, 30x3½ and **31x4.** The latter size being an oversige for 30x3½, or can be fitted to 30x3½ rims—see page 555.

The Ford uses 30x3 in front and 30x3½ rear, plain clincher on, one-piece clincher rims permanently fitted to wheel on touring car and roadster. On the Ford Sedan and Coupelet, also Maxwell, Chevrolet and Overland Model Four, the 30x3½ tire on "one-piece clincher rims" but with the "demountable" feature is employed.

†Proper Air Pressure.

There are four ways in which you can save on tire bills; first, by keeping the tires at all times well inflated; second, by using your brakes with caution; third, by not overloading the car; fourth by repairing small cuts in the tread as they appear and being sure wheels are in alignment.

More than three-fourths of all tire trouble is caused by under-inflation. A soft tire by having its sides bent at a sharp angle, will soon have its fabric loosened from the rubber, with consequent liability of an early rupture. Besides, a hard tire presents less surface to the road and is therefore less likely to suffer cuts and punctures.

One manufacturer gives the following rule for inflation of tires. The pressure of air to be carried is about 18 pounds per inch (cross section); for instance, a 3-inch tire ought to have 54 pounds and a 3½-inch, 63 pounds, and so on. The pressure can be accurately tested with a pressure gauge, a good form being shown in chart 238.

Another manufacturer gives this schedule as per chart 236-A. In addition, the **wheel load** each size of tire is supposed to carry and how to figure the wheel load is given.

The most important thing to fix in mind on the subject, is that load as well as **inflation**, must be considered to get good results. These two factors are interdependent. You cannot consider one properly without regarding the other.

If you increase the load imposed on a given tire you must increase the inflation pressure—and vice versa—if you are to maintain this proper degree of flattening.

From this it will be seen that there is no fixed pressure than can be set as standard for any size of tire regardless of load.

That the inflation pressure should vary in tires of a given size according to the load they are obiged to carry, is obvious when you consider, for instance, a **4-inch tire used on a heavy touring car and another 4-inch tire used on a light roadster.** Obviously the weight on the former is a great deal more than that on the latter, so that the former tire will be flattened or distorted a great deal more, providing tire pressure is the same. In order to prevent this flattening from becoming abnormal and in that way affecting the tire detrimentally, it will be necessary to maintain a higher inflation pressure in the touring car than used in the tires on the light roadster.

If the tire is inflated so that it does not flatten at all under the load more service will probably be received from it. However, this will cause the car to ride harder.

If the tire is underinflated, that is, if the amount of air allows too great a degree of flattening, the constant distortion at its point of contact with the ground as the wheel revolves, will generate heat in the side walls of the tire. This heat destroys the rubber between the individual plies of fabric and tends to separate them. Separation of this kind weakens the tire so it is not long able to stand up under ordinary road conditions.

To Get Better Cushioning; Change to Oversize.

If it is desired to increase the durability or mileage from the tires, the inflation pressure should be increased. In extreme cases where better cushioning effect is desired this can be done by decreasing the inflation pressure. However, that is bound to cut down the mileage received from the tire. The best way to **get better cushioning is to change to oversize tires** because in that case a lower inflation pressure can be used. For instance:

Suppose that a 4-inch tire carrying a weight of 1,000 pounds per wheel should according to the scale, be inflated to 80 pounds. If the motorist found he wished easier riding, the best thing he could do would be to change over to 4½-inch tires, which with a load of 1,000 pounds would need to be inflated to only about 70 pounds.

The big thing to remember in connection with proper inflation in tires, is that it is underinflation and not overinflation that ought to be guarded against.

Inflation Pressure During Hot Weather.

The subject of whether or not inflation pressure in tires should be reduced in hot weather is a very interesting one, because it is generally supposed the pressure should be reduced in the summer time.

In a test made with a 33 by 4 tire on the hottest day ever recorded here in June, we found that although driven at excessive rates of speed, the increase in inflation pressure amounted to only 4 pounds, which of course, is negligible, because many times 4 pounds would not cause the tire to blow out.

Tire gauges are shown on page 568.

Air Compressors.

Hand tire pumps are made in single and double acting, the most satisfactory type is the double acting, as shown in fig. 4, chart 237.

Power pumps or air compressors are driven in various ways; the spark or impulse pump; friction wheel, the belt or gear driven and electric motor driven pump. Modern cars are equipped with small air compressor driven from the engine.

Air compressors for garage use are described under "Equipment for the garage." See chart 237-B for air compressors.

†**Cord tires** per page 559 require slightly less air pressure than "fabric" tires.

CLINCHER RIM MEASUREMENTS

Size	Inside Diam. of Rims for Wood Wheels	Diam. of Rim at Tire Seat for Wood and Wire Wheels	Size	Inside Diam. of Rims for Wood Wheels	Diam. of Rim at Tire Seat for Wood and Wire Wheels
26 x 2½	20.834″	21	34 x 3	27[illegible]″	28

†The pressure to be carried in tires and the wheel-load that the different sizes are intended to carry is shown above.

To find the wheel load for any particular car: First, it is necessary to know the weight of the car, with all the passengers and accessories, water and gasoline tanks filled and on board. After weighing the whole car, weigh back of car. To do this, the middle of the step of the car should be over the edge of the platform scale—if a regular wagon scale is not available.

Weigh the front of the car in the same way, the middle of the step being over the other end of the platform. If this has been carefully done, the last two weights added together should give within twenty pounds of the total weight of the car when weighed complete. Of course the wheel loads are one-half of the respective axle loads as found in this way. In this way you can see if your car is tired properly by referring to the scale showing the size of tire to use.

Oversize tires: All tire makers agree that a larger size tire, giving a larger air cushion, is better than a smaller tire with a smaller air cushion. If you think your tires are too small, place a larger size tire on the rim. (See list above "Standard Oversize Tires.")

You can figure the oversize tire your rim will take by adding one-half inch to the cross-section and one inch to the diameter. For instance, suppose your present tire is a 32x3½; by adding one inch to the diameter we have 33 and adding one-half inch to the cross-section we have 4, therefore a 32x3½ rim will take an oversize tire 33x4.

Transposing tires: Ruts, curbings and similar tire destroyers may wear the outer wall of a casing nearly to the fabric, but if the tire is reversed, and that side which has been exposed and most worn placed nearest the car, it will still be serviceable.

As the rear tires sustain more than half the burden in every movement of the car, they will wear more rapidly than the front tires; they also have to bear the traction strain, that of carrying the car forward, and for these reasons they are subject to more wear than the front tires. Furthermore whenever the car is stalled in a mud hole, the rear wheels revolve a great many times without the front ones moving.

Many motorists follow the practice of using repaired tires on the front wheels and new ones on the rear wheels. Increased service can also be had by transposing tires. In ordinary wear it is usually true that tires on the right side become worn more quickly than those on the left. This is due to their being run into ruts and stones, when the car is turned out of the traveled roadway, and because the tires of the right side suffer most from curbings and the like as the driver uses the right side of the street, they also carry more than half of the weight when the car leans, which it does mostly on the right side.

The right rear tire wears faster because of the curve of the streets and roads. The weight being more on the incline is probably the cause.

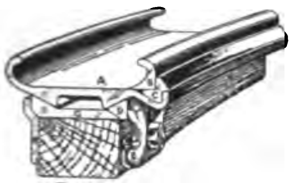
S. A. E. STANDARD SIZES OF PNEUMATIC TIRES FOR PLEASURE CARS

Rim Sizes	Even Tire Sizes (for manufacturers and consumers)	Odd or Oversize Tires (for consumers only)	Tire Seat Diameter
30x3	30x3	31x3½	24″
30x3½	30x3½	31x4	23″
32x3½	32x3½	33x4	25″
32x4	32x4	33x4½	24″
34x4	34x4	35x4½	26″
34x4½	34x4½	35x5	25″
36x4½	36x4½	37x5	27″
36x5	36x5	37x5½	26″
38x5½	38x5½	39x6	27″

See bottom of page 555 for change of tire sizes.

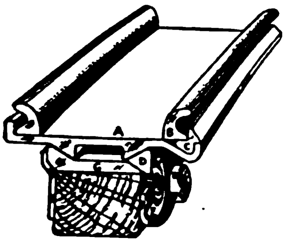
CHART NO. 236-A—Useful Information Relating to Tires.

*Figures in 1st column represent milli-meters. See page 541 for explanation of milli-meters. †See page 559 for pressure to be carried in cord tires.



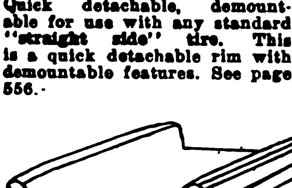
Type A

Type A — Firestone Rim. Quick detachable and demountable. This rim takes a plain "clincher" or a "quick detachable clincher" tire. Tire can be removed without removing rim, or the rim and tire can be demounted.



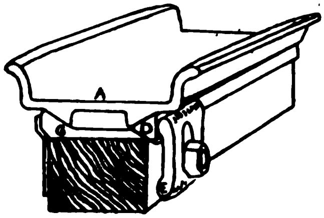
Type B

Type B — Firestone Rim. Is also a quick detachable, demountable rim, but the side ring (B) can be reversed for use with any straight side or Q. D. tire. Therefore this rim will take a plain "clincher" or "quick detachable clincher" or "straight side" tire. By removing the clamp the rim with tire is demountable. This is called the universal rim.



Type C

Type C — Firestone Rim. Quick detachable, demountable for use with any standard "straight side" tire. This is a quick detachable rim with demountable features. See page 556.



Type E—Firestone Rim. A demountable one-piece rim for straight side tires. It is a split rim, see figs. 4 and 5, chart 236B.

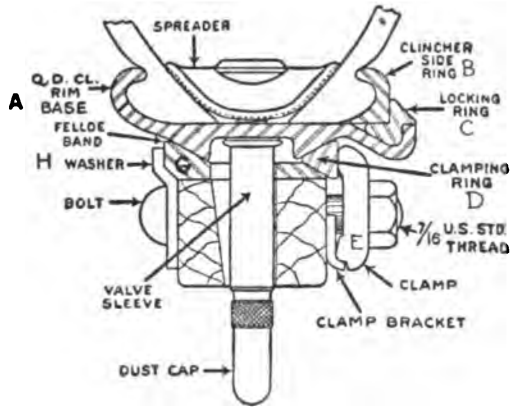


Figure 1

The valve sleeve can best be explained from the instructions given by a prominent tire manufacturer as follows:

Be sure that valve sleeve, sent out with every set of Firestone demountable rims, is being used. This is an important feature of this rim as it serves to hold steel valve spreader securely in place, making it impossible to throw a tire even when deflated, prevents moisture from working into the tire around the valve stem, and the dust cap need not be removed when the rim is mounted or demounted.

*Quick Detachable Rims.

Type A—Firestone Quick Detachable, Demountable Rim: A—Rim Base. B—Side Ring. C—Locking Ring. D—Clamping Ring. E—Clamp. F—Clamp Bracket. G—Felloe Band. H—Belt Washer.

Type B—Firestone Quick Detachable Reversible Demountable Rim. A—Rim Base. B—Reversible Side Ring. C—Locking Ring. D—Clamping Ring. E—Clamp. F—Clamp Bracket. G—Felloe Band. H—Bolt Washer.

Type C—Firestone Quick Detachable Demountable Rim: A—Rim Base. B—Side Ring. C—Locking Ring. D—Clamping Ring. E—Clamp. F—Clamp Bracket. G—Felloe Band. H—Bolt Washer.

Type E—Firestone Demountable Split Rim: A—Straight Side Split Rim Base. D—Clamping Ring. E—Clamp. F—Clamp Bracket. G—Felloe Band. H—Bolt Washer.

Standard Sizes of Pneumatic Tires After Nov. 1, 1920.

30x3½	clincher
31x4	clincher
32x3½	straight side
33x4	straight side
32x4	straight side
32x4½	straight side
33x4½	straight side
34x4½	straight side
33x5	straight side
35x5	straight side

Above are made in fabric construction in "plain" and "non-skid" tread. Made in cord construction in "ribbed" and "non-skid" tread.

Sizes To Be Discontinued Nov. 1, 1920.

30x3	clincher
31x3½	clincher
34x4	straight side
35x4½	straight side
36x4½	straight side
37x5	straight side

Oversizes.

31x4 is oversize for a 30x3½; 33x4 for 32x3½; 33x4½ for 32x4; 34x4½ for 33x4; 33x5 for 32x4½; 35x5 for 34x4½. See page 554, how to figure oversize tires.

Pneumatic Truck Tires.

36x6
38x7
40x8
42x9
44x10

Above made in straight side, non-skid of cord construction only.

CHART NO. 236-AA—Examples of Quick Detachable Demountable Type of Rims (Firestone) o type A, B, C and E Rims.

*The straight side rim is the popular rim.

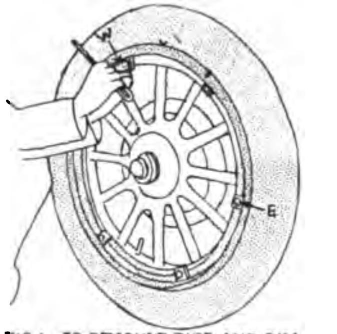

FIG. 1 - TO DEMOUNT TIRE AND RIM LOOSEN SIDE CLAMP "E" WITH SOCKET WRENCH "W"

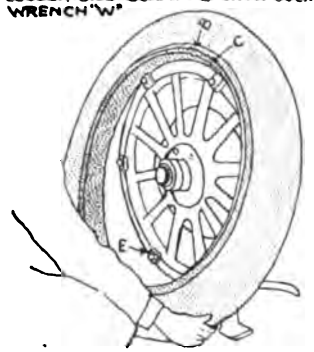

FIG 2-DEMOUNTING RIM, TIRE AND ALL FROM WHEEL

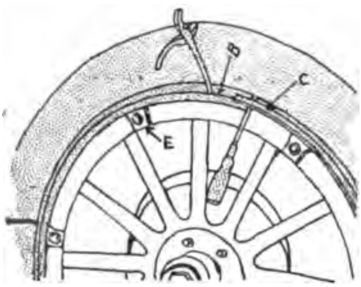

FIG 3 TO REMOVE TIRE FROM RIM PRY OFF LOCKING RING C

Demounting and Mounting Q. D. Tires Side Ring Type.

To demount the rim from the wheel (applying to type A, B and C): Jack up wheel and loosen clamps (E) using the socket wrench (W) which accompanies each set of rims. Slide each clamp down as far as it will go (fig 1), then tighten nut sufficiently to hold clamp in that position.

The socket wrench supplied may be operated with one hand while the other hand is employed to steady wheel. See fig. 1.

When all clamps have been freed, turn the wheel so that the valve stem is at top, then swing out lower side of rim (fig. 2) and lift rim, tire and all, off the wheel.

The valve hole in felloe is tapered so this can be done without straining the valve stem. Note—It is not necessary to remove dust cap when demounting rim. Dust cap should always be kept screwed tightly against the valve sleeve, except when detaching the tire from its rim.

To mount the spare rim with inflated tire (applying to rims A, B and C.). Having taken clamping ring from rim just removed, place in same position (with point toward inside) in spare rim carrying inflated tire.

Turn the wheel so that the valve hole in felloe is at the top; insert valve stem (with dust cap and valve sleeve already on same) through hole and swing the lower part of rim snugly into place. Ends of clamping ring should come under one of the clamps.

Restore each clamp in turn to its original position, over-lapping the clamping ring, giving the respective nuts one or two turns with the wrench to hold the clamp fairly tight. Then continue around the wheel again, tightening down all nuts and clamps firmly.

To apply the tire to A, B or C rims: Place the slightly inflated inner tube in the casing, using plenty of soapstone or talc, and set casing back on rim.

Put on the clincher side ring. Apply locking ring by engaging the pin in notch in edge of rim and then force the locking ring into its groove around the wheel. Inflate tire to proper pressure.

Screw dust cap on tight against valve sleeve.

The spreader is held in position in the base of the tire by the pressure of screw dust cap against valve sleeve. No locking nut or other device is necessary.

To remove tire from types A, B or C rims: Remove dust cap and allow the air to escape. Push the valve stem up into the tire as far as it will go, thereby releasing the pressure of the spreader inside.

Insert point of screw-driver between side ring (B) and locking ring (C), fig. 3). Pry downward, causing an opening between the two rings. Drop a coin or other convenient piece of metal into this opening and hold opening thus gained. Pry downward with screw-driver, which will remove locking ring (C). Bead ring and tire may now be removed from rim. Note valve sleeve will remain in valve hole of rim or felloe.

Demounting and Applying; Split Rim (Type E).

The type E rim, figs. 4 and 5, are the split type. To remove, loosen clamp bolts.

To remove tire from type "E" Firestone rims without aid of operating tool: Be sure cam button lock (T) is unlocked. This type of rim is split (at R) and a button which is slotted and on the inner side of ring is operated with a screw driver. To prepare rim for removing tire, turn button so flat edge (not shown) is parallel with end of latch. Grasp tire in both hands and strike firmly on ground at a point indicated by S, causing rim to collapse, as indicated in cut Then turn tire half way around to position as shown in fig. 4. Throw your weight onto rim, and tire may be pulled off with hands. Or insert screw driver, or similar tool, under both beads, and tire may be pried off with ease.

To apply tire on type E rim, without rim tool: After collapsing the rim in manner of fig. 4, lay rim on ground, insert valve stem in hole in rim, stand on beads of tire and "walk" same over flange of rim working to the right from valve around rim. Note fig. 5.

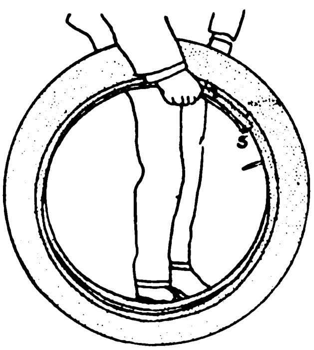

FIG 4-TO REMOVE TIRE FROM TYPE "E" RIMS WITHOUT AID OF OPERATING TOOL

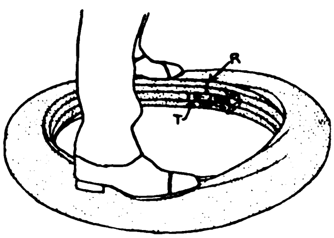

FIG 5-TO APPLY TIRE TO TYPE "E" RIM WITHOUT RIM TOOL

CHART NO. 236-B—Demounting Rim, Mounting Spare Tire, Applying Tire to Rim—of Type A, B, and C Firestone Rim as an Example. Demounting Type E Rim.

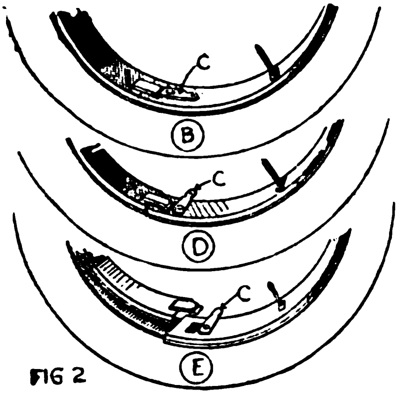

FIG 2

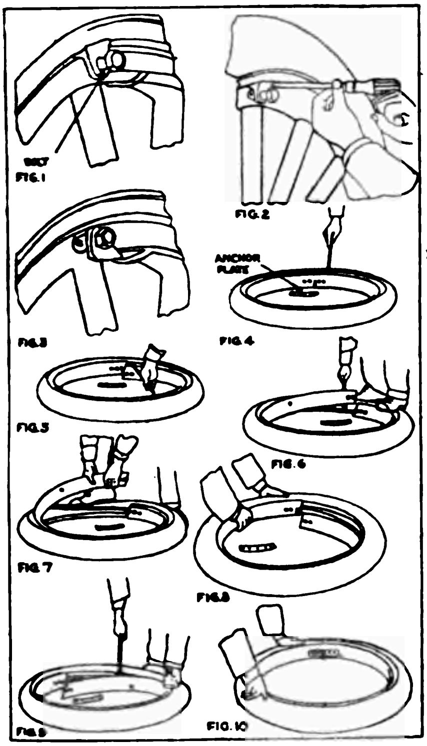
The Split Rim.

In fig. 2 a split rim is shown with a locking lever C. The rim is called a split rim because it is not endless but is cut through on one side. When rim is removed the locking lever (C) is thrown to one side as at (D). The rim is then pried out or lapped (E) and tire pulled off.

When rim is put back in place the lever C is put in place as at (B). The type E rim chart 236-B is of the split type but has a different locking device.

Another type of split rim is shown below in figures 1 to 10 and is similar but a different locking principle. We will use this type below to explain how the rim and tire is demounted; how tire is removed from rim and how replaced. The procedure is very similar on all types of split rims.



The Baker bolted-on type split rim—used on the Buick as example, see figures 1 to 10.

The demountable rims supplied with Buick cars are known as the Baker bolted-on type and may be removed from the wheel with the tire. The operation is as follows:

To demount rim and tire: With the brace wrench, loosen all bolts about ¾ inch, (fig. 1) except the ones on each side of the valve stem. Insert screw driver at right hand side of wedge, between rim and wheel (fig. 2), and strike handle of screw driver to free the wedge. When free, turn wedge around, (fig. 3), and tighten bolt to hold wedge in this position so it will not interfere with rim while dismounting.

To take rim out of tire, lay rim and tire flat (fig. 4), so that the end of the cut in rim farthest from the valve stem is up. Remove anchor plate and beginning at end of rim which does not have the valve stem, insert sharp end of tire tool under bead of tire. Force down end of tire tool in hand (fig. 5), until end of rim is out of tire. This will bring the two short sides of the rim together, thus reducing its circumference. Repeat operation, as necessary, to free rim. Next, turn rim and tire completely over (fig. 6), and force tire tool between both beads of tire and rim, then holding tire with the foot (fig. 7), grasp free end of rim and pull it out of the tire.

To replace tire on rim, lay rim flat on the ground with tire on top (fig. 8). Raise end of rim which is drilled for the valve stem, and after valve stem has been inserted, put both beads of tire entirely into the end of rim that has been raised, making sure that other end of rim is under both beads of the tire. After the beads of the tire have been properly started, insert them all the way around, leaving other end of rim to be put in last. If the tire is too stiff to force on by hand, use tool, fig. 9. Add anchor plate and valve cap after inflating (fig. 10).

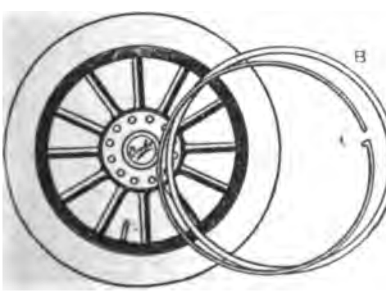


Fig. 12. Side ring type of Q. D. rim. B—is the endless ring. C—is the other.

Demounting Side Ring Type.

Fig. 12—This type of rim is the side ring type of quick-detachable demountable rim, similar to fig. 8 chart 236-B. The illustration shows the locking ring (C) and side ring (B) removed and tire ready to be removed from rim, see also chart 236-AA.

When replacing, push the casing back as far as it will go; replace the side ring (B) and finally the locking ring (C), by first inserting the stud of the latter in the hole and working the ring all around into the groove.

The locking ring is inserted most easily while the casing is being pushed back as much as possible. When this is done in the proper manner it is not necessary to use a hammer in order to seat the ring into its groove.

CHART NO. 236-C—The "Stanweld" Rim. The Quick Detachable Type of Rim with a Locking Ring. The "split" rim must be removed from wheel to remove tire. In type shown in fig. 12, called the "side ring" type, the tire can be removed with rim on wheel, or demounted.

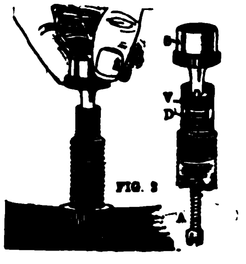

Fig. 2 — Shows how the valve cap B is reversed to unscrew the inner valve (A) when tube is to be deflated.

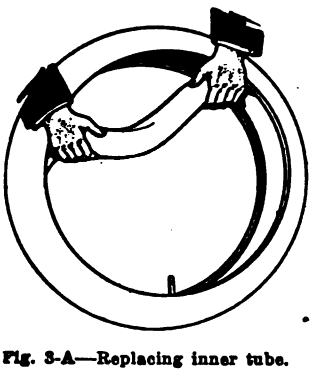

Fig. 3-A—Replacing inner tube.

Fig. 2-A—Removing inner tube from tire.

Fig. 1—The First Operation in removing a tire cover: After the lug bolt wing nuts have been slacked off, the edge of cover is pushed out of the rim and the tire levers inserted.

Various forms of levers are obtainable, some being more convenient to use than others. Most of the tire makers supply suitable levers for their tires.

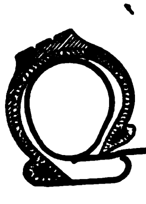

Fig. 2—Second Operation: The lever raising the cover over the edge of the rim. Special care must be taken not to pinch the air tube between rim and lever. This would result in damage to the tube, rendering it useless till repaired. Even if not cut through, the rubber would be so much weakened as to burst under the effect of air pressure on some future occasion.

Fig. 3—Third Operation: The hand is used in assisting the working of cover down outside of the rim, the lever being in position between cover and rim. A new cover will generally be found stiff to manipulate with the hands for the first time, but soon becomes supple with use

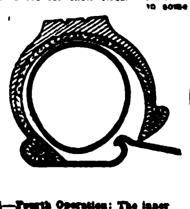

Fig. 4—Fourth Operation: The inner tube having been carefully replaced, the hooked end of the lever is used to work the edge of cover back into the rim.

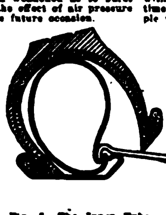

Fig. 5—The Inner Tube has been pinched by tire tool

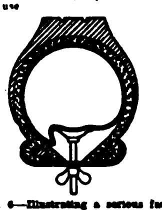

Fig. 6—Illustrating a serious fault. The inner tube has become nipped between one of the lug bolts and cover, and unless released will result in a burst tube. This risk is avoided by taking care to moderately inflate tube before replacing in cover.

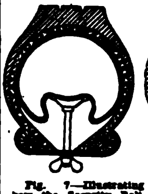

Fig. 7—Illustrating how the Security Bolt, by being pushed towards inside of tire before screwing down, allow cover and tube to fit into the correct position. The ordinary security bolt has a canvas-covered head which sometimes causes air tube defects, such as nipping and chafing. If bolts with moulded rubber heads be used these defects are not likely to occur.

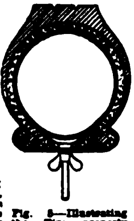

Fig. 8—Illustrating the Tire properly Fitted, the security bolts in place, and inner tube snugly in its place, no nipping at any part. The tire when pumped up should be even all the way round the rim, and run truly when the wheel is rotated.

Above illustrations show how to remove and attach a tire on a "one-piece" clincher rim.

Fig. 4A.

To Remove an Inner Tube.

Jack up wheel. Remove the valve cap and inside valve by reversing the cap head and unscrewing it as shown in fig. 2. Remove lock nut on valve stem (see (H) fig. 6, chart 235).

Push edge of casing from under the lip of rim with tire tool as shown in fig. 1. Pry off as in fig. 2 and 3. This operation must be repeated all around the tire until the outer bead is loosened. The inner tube can then be removed and outer casing slipped off.

When taking an inner tube out of tire, turn the wheel until the valve stem is at the bottom, as in fig. 3-A, remove the tube, beginning at top.

Always make it a point to run your hand around inner tube in the casing until you detect the cause of the puncture, because very often the offending object is hidden in tire and cannot be seen or felt from outside.

Replacing Inner Tubes.

Put in a new tube, or patch the old one in accordance with the instruction further on; the **inserting of the tube may be done with the casing remaining on the rim or with it removed.** In either case it is desirable to turn the wheel until the valve stem hole is on top (fig. 3-A). Before the tire is replaced, the inner tube should be slightly inflated.

Place powdered soap stone or mica in case before inserting tube, fig. 4-A. (Too much of this however is likely to work up into little balls and cause inner tube trouble.)

Then run your hand around the inner tube, smoothing out the creases and placing the tube evenly around the rim.

Do not inflate the tube too much when placing it in a tire, for if you do, you will have difficulty in replacing the locking rim over the bead of the casing.

Inflate the tire carefully after it is properly attached, and test the increasing pressure with your hand.

Occasionally the tube is pinched under the spreader. Push the valve stem up and down with your hand before inflating. When the valve returns to its original position there is no danger of pinching.

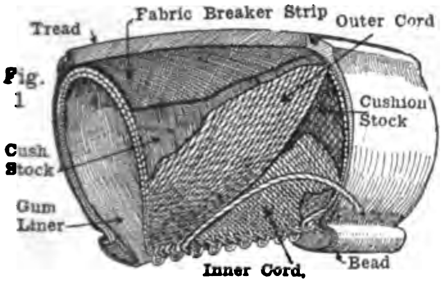
CHART NO. 236-D—Removing and Replacing Inner Tubes. Removing and Replacing the Clincher Tire on the "one-piece" Clincher Rim. The "one-piece" plain clincher rim is now seldom used.

The Cord Tire.

The cord tire differs from the fabric tire previously described in that instead of sea island cotton or other closely woven and interwoven fabric being used for the carcass of the tire, cords are used which are loosely woven and not interwoven.

There are two kinds of cord tires, the "cable cord" and the "multiple cord."

The cable cord tire is known as the Silvertown cord tire and is a product of the Palmer Tire Co. of England made in a suburb of London called Silvertown. This tire is made in this country by the B. F. Goodrich Co., the Carlise, and Fiske.



The multiple cord tire is made by the Firestone, Goodyear and some of the other tire manufacturers.

The difference between the cable cord and the multiple cord tire is in the size of the cords and the number of plies of cords. In the **cable cord tire** there are two to four plies of heavy cable cords.

In the **multiple cord tire** there are 6 to 8 layers or plies of smaller cords or threads.

The cord tire is far stronger than the fabric tire, one principle reason being that the cord tire is not so closely woven or **interwoven** as the fabric carcass tire and therefore not broken so easily, as with the fabric tire it is continually sawing itself as if it were being bent back and forth and eventually breaks. Another advantage is that a cord tire is not subject to stone bruises as explained on page 566, as the cords all run one way and are not interwoven as fabric, and the result is they will give without breaking when tire strikes a stone at high speed, or in other words, the carcass will have same action as the tread—it will stretch under blow without breaking.

For an example of the construction of the cord tire we will use the "cable cord" tire as an example per fig. 1.

The **inner lining** of a tire is made of a rubber sheet, then the first or **inner layer or ply of cable cord** is laid and then two sheets of pure gum are applied to act as a **cushion** between this and the next ply of cord. The **second or outer layer of cord** is then applied at right angles or at angle of 45 degrees to the first layer, then two layers of gum cushion stock, then a fabric **breaker-strip**, then the **tread.**

The body or carcass of the tire as it will be noted, is made of two plies or layers of cords, instead of fabric. These cords are made of cotton fibre, about the size of heavy sewing cotton, twisted into cords about the size of ordinary grocery store twine, but stronger. These cords in turn are woven into cables.

Throughout the process, all units are impregnated, under heavy pressure (hundreds of pounds to the square inch) with a solution of pure, fine rubber. This has much the same effect as waxing shoemaker's thread. The solution permeates every fibre, being literally driven into it.

Treads: There are two types of treads used on cord tires, the "ribbed tread" per fig. 8A, page 550 and the "safety" or "non-skid" tread.

The air pressure carried in the cord tire is slightly less than a fabric tire, for instance, 3½" size 50 lbs.; 4" size 60 lbs.; 4½" size 70 lbs.; 5" size 75 lbs.; 5½" size 80 lbs.

Cord tires are made in following sizes: *30x3½; *32x3½; *32x4; *33x4; *34x4; 32x4½; 33x4½; 34x4½; 35x4½; 36x4½; 33x5; 35x5; 37x5.

Beads of tires are made for Q. D. clincher and straight side rims where marked *, the other sizes are made for straight side rims. Only straight side bead tires will be made in the future.

A heavy truck tire of the cord type is made in 36x6 size. The Firestone Co. make pneumatic cord tires for commercial use in 6, 7, 8 and 10 inches cross section called "Giant Cord Tires."

Airplane tires of the cord type are made in 26x4 and 32x4½ sizes.

The cord tire is a higher priced tire than the fabric tire but is the popular tire, as it will outwear the fabric tire and is well worth the difference. This is due to its strong construction, yet is resilient and easy riding and cords do not break as readily as interwoven fabric.

Cord tires can be made in the "molded" or "wrapped tread" method, per page 565.

Tire Protectors.

There are two methods for making a tire puncture proof:

The steel disc type of puncture proof tire fig. 4 consists of three layers of 7/16" diameter steel discs about 1/64" thick, imbedded in rubber between the fabric and tread of tire. The layers of discs are placed in such a manner that it is impossible for a nail to enter the tread of tire without striking a disc. This tire is called the Lee puncture proof tire.

The leather lined puncture-proof tire consists of a special made tire on the **inside** of which is a puncture-proof strip of chrome leather which is intended to prevent punctures without stiffening the tire. This tire is known as the Woodworth trouble-proof tire.

Another example is the outer leather cover made of water-proof chrome leather studded on the tread surface with steel rivets. These covers completely enclose the tire and are attached to the rim, per fig. 5. The manufacturer claims they are particularly valuable to use over old tires or re-tread and strengthen them and also valuable to people who have to run over roads that are rough, rutty and rocky, and who travel at less than 25 miles per hour. (Woodworth Mfg. Corpn., Niagara Falls, N. Y.)

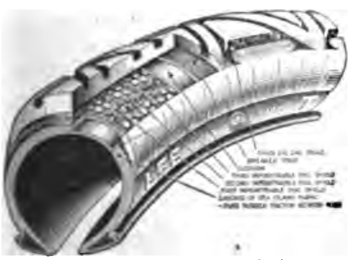


Fig. 4: Lee puncture proof tire.

Fig. 5.

*Spring Covers.

Fig. 6. Woodworth spring cover and lubricator laces over the spring, preventing any danger of moisture or dirt getting between the leaves. The cover is lined with a felt wicking which is saturated with oil before the cover is put on and will hold enough oil to lubricate the springs for 10,000 miles. The smooth gliding effect is obtained which, is so noticeable in a new car with perfectly lubricated springs. (Woodworth Corpn., Niagara Falls, N. Y.)

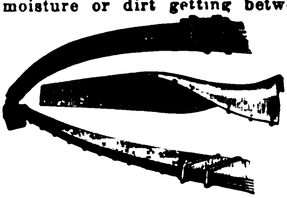

Fig. 6.

CHART NO. 236-E—The Cord Tire. Tire Protectors. Spring Lubricator.

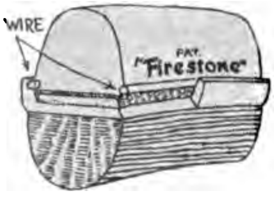

Fig. 1.—Side wire solid tire. The original automobile tire, now used on light trucks, trailers, cabs, horse-drawn vehicles, etc.

Fig. 3.—The hard base tire on removable rim.

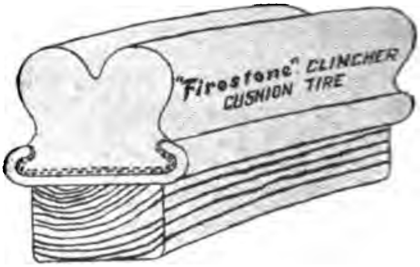

Fig. 5.—Firestone clincher cushion tire interchangeable with pneumatic tires on regular clincher rims.

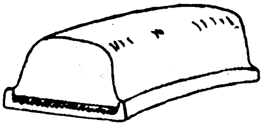

Fig. 2.—The hard base pressed-on type of solid tire.

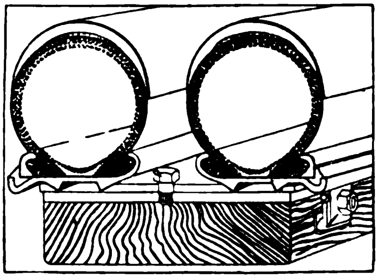

Fig. 7.—Firestone dual pneumatic tires on quick-detachable rims used on heavy cars of high speed.

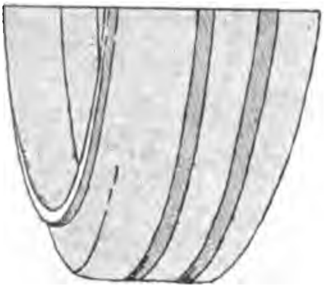

Fig. 4. — The Firestone "Giant" solid tire designed especially for heavy hauling. Made in 8 in. 10 in., 12 in. and 14 in. width treads. It replaces dual equipment for certain classes of heavy service. The tread is grooved.

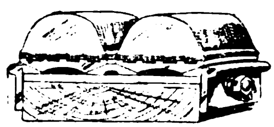

Fig. 11.—Goodyear dual demountable solid tire.

Solid Tires.

****Solid tires are used principally on trucks and electric vehicles, and are divided into two classes, as follows: single and dual.**

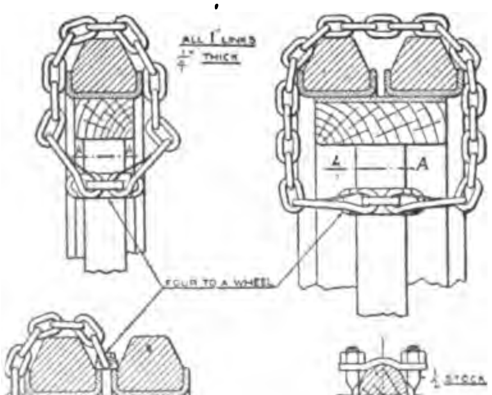
The single solid tire is fitted on different types of rims. On one type the tire is pressed on to the rim as in fig. 2—in another the rim is of the quick-detachable type (fig. 3), and in another the rim and tire is demountable.

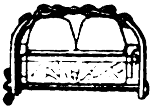
The dual tire is divided into two classes; the block type and solid. The block type is made up of sections. If one becomes damaged it can be re-placed.

The solid cushion tires are used extensively on electric vehicles.

Size of Solid Tires to Use.

SINGLE		TWIN	
Size Inches	Extreme Load per Wheel Pounds	Size Inches	Extreme Load per Wheel Pounds
2	500		
2½	750	2½	1900
3	950	3	2500
3½	1375	3½	3500
4	1750	4	5000
5	2000	5	6000
6	3000	6	8000
7	4000		

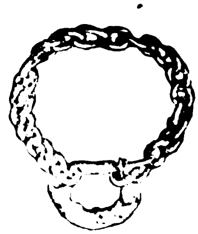




Chains for Solid Tires.

Chains are essential for gripping the road, snow, ice, etc. Several methods of applying chains and grips are shown on this page. The Woodworth Co., Niagara Falls, N. Y. manufacture a good chain grip for solid tires as shown below.

Either twisted links or straight link chains may be used on solid tires as shown. Should be applied at 4 points on each rear wheel. They should be removed when not required. Illustration, below to left, is where clearance will not allow chain on inside tire (Gen'l Vehicle Co.).



Woodworth chain grip, for truck tires.

*Solid Tire Repairing.

The solid tire cannot be successfully vulcanized. Therefore the only recourse is to run the tire as long as possible. The solid tire business of applying tires and rims is a profitable business.

CHART NO. 230-F—Solid Tires. Chains or Grips for Solid Tires.

Solid Tire Troubles are mostly in cuts and bruises which soon causes to wear rapidly—due to—driving in car racks; neglected cuts; chains too tight; out of alignment; skidding; overloading; speeding and bad roads. If chains are used—have them loose. **See also, page 589. See page 555 for Pneumatic Truck Tires.

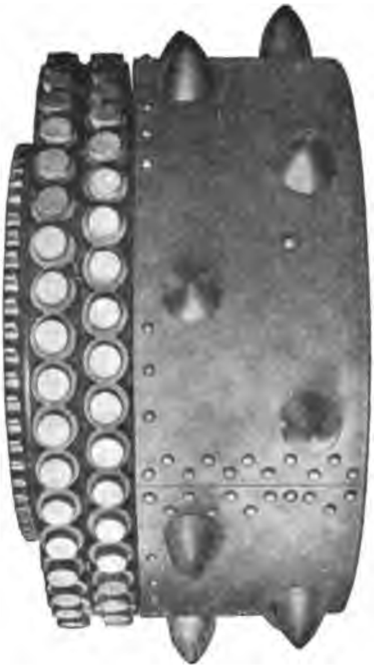


Fig. 5—Special wedge shaped and round cast iron plugs: The illustration above shows an Avery cast steel rim wheel with wedge shaped and round cast iron plugs in place of the regular hardwood plugs. In this case the two styles of iron plugs are placed alternately. They can be used in any manner desired. The wedge-shaped plugs are particularly useful and a few of them placed in a wheel enables it to travel over much softer or muddier roads than otherwise.

Fig. 4—Wood plug extension rims are made in either a one or two row wood plug extension rim. The single row rim increases the width of the wheel to 9 inches and the double row to 12 inches.

Fig. 3—Flat steel extension rims with heart shaped lugs: The 6 inch pair of these rims placed on the rear wheels increases the face of each wheel to 12 inches; the 12 inch pair increases the face to 18 inches.

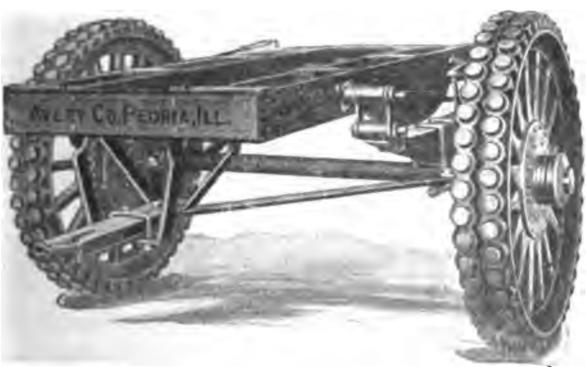

Fig. 6—For coupling on wagons or other machinery to a truck—this coupling is automatic.

Fig. 2—Automatic paddle wheel extension rims: Automatic in action. They consist of two wrought iron bars between which are heavy cast lugs 8 inches in width. These lugs are mounted on pivots, and the points are held below the surface of the wheel rim by means of springs. When the wheels travel over muddy roads or soft ground and sink so that the points of the lugs touch the ground, the revolution of the wheels causes the lugs to be extended vertically 4¼ inches above the surface of the wheels, forming a solid bearing surface against which to push. They are drawn back by springs and go out of action when not needed, and automatically go into action the moment they are required. The lugs can be fastened permanently in an extended position if desired.

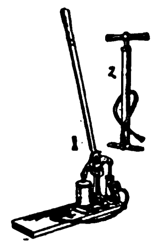

Fig. 1—Two types of hand air pumps.

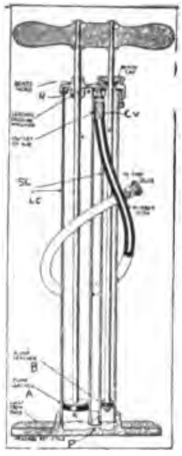

Fig. 4.

Hand and Foot Air Pumps.

Fig. 4—A compound hand air pump principle is the same as that employed in a power pump, that is the air is sucked in from atmosphere into large cylinder at (H), compressed by the down stroke of the handle and at the same time it is forced into the smaller cylinder at (P). The up stroke of the pump forces the air from smaller cylinder into the tire through check valve and hose (CV) and large cylinder sucks in another charge. While the air admitted into the large cylinder is receiving its first compression, it is forced through passage (P) (connecting the two cylinders) and up past cup leather (B) into the upper portion of the smaller cylinder. The cup leathers (A) and (B) are fitted to their pistons in opposite positions, that is, the leather (A) is put in with its open side downward and leather (B) has its open side upwards. If both leathers are put in the same way, the pump will not work. A pump of this kind differs from a single cylinder pump, in that each stroke is a power stroke, whilst in a single cylinder pump only the down strokes are power strokes. Keep leather packing washer (around piston rod of small cylinder) tight, otherwise the air will blow through here instead of going into the tire.

Every up stroke of piston (B) forces into tire an amount of air equal to the volume of the large cylinder at atmospheric pressure.

The same principle applies for using a two-cylinder or compound tiré pump instead of a single-cylinder one, as applies in the use of a two-cylinder or compound steam engine.

There is also another type of compound hand pump on the market which differs with the above, in that it is double acting as well as compound—both pistons working in both directions of stroke. While the air is receiving its first compression, it is lead through a by-pass to upper portion of small cylinder instead of the lower. The hose connection is at the bottom instead of at the top.

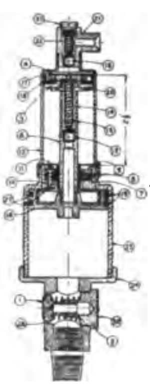

Fig. 5—The spark plug or impulse pump, as it is sometimes called, is of the type which screws into a spark plug hole and operates through the compression of the engine.

26—Inlet valve seat.

The Spark Plug or Impulse Pump.

Fig. 5—This pump has the appearance of a compound pump, due to the large and small cylinders, but they are built thus to make it possible to pump the high pressures necessary for large tires, and at the same time not have any too good compression in the engine cylinder. The lower piston with its large area, receives its impulse from the compression in engine cylinder, and transmits it to the upper piston through the medium of the hollow piston rod, to which both pump pistons are attached.

Action—as the engine piston makes its suction stroke, it draws fresh air through valve (1) which opens inwardly, and at the same time, both pump pistons make their downward stroke. You will note that piston rod (6) is hollow, this is the air passage to upper cylinder through ball check (12). As the engine piston makes its compression stroke, it forces its charge of compressed air into the upper cylinder and against lower piston of pump and causes it to make an upward stroke, this piston being so much larger than the upper piston, the charge is further compressed and sent through outlet valve (21), at the top, thence through hose to tires or tank.

These pumps are very often spoken of, as compound pumps, due to the fact that the air pressure is raised in two stages, but don't forget that the first stage is performed in the engine cylinder and not in the pump cylinder. It is a single stage pump, capable of raising the pressure from 50 or 60 lbs. in engine cylinder, to 100 lbs. or more in tire or tank.

It is advisable to let the pump make a few strokes, before attaching hose to tire valve.

Power Driven Tire Air Compressor.

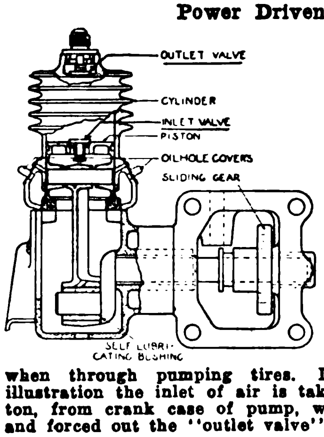

Illustration is of the compressor used on Cadillac car. It is bolted to left side transmission case and driven by a sliding gear which meshes with reverse idler gear in transmission. The sliding gear is thrown in when needed and out when not needed, by a lever.

To operate; stop engine, wait until transmission gears are idle, then shift gear of compressor in mesh with the reverse idler gear. Then start engine, being sure gear shift lever is in neutral position.

Run engine at speed of 900 to 1100 revolutions per minute. This is indicated by ammeter showing 16 or 18 amperes, if third brush is properly regulated on generator. Do not race engine when inflating tires. Throw gear out of mesh when through pumping tires. Lubricate compressor often. By observing illustration the inlet of air is taken in through "inlet valve" in top of piston, from crank case of pump, when piston travels down. It is compressed and forced out the "outlet valve" as piston travels up.

CHART NO. 237—Air Pumps; Hand and Power Types.

For air hose a special heavy connection for the air hose is necessary. For placing over tire valve for inflating tires. Made to fit 5 16 and ¼ inch hose. Two types of connection are shown.

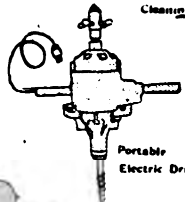
Illustrating how the connection from air pump (driven from engine spark plug or friction pump) to tire is made. The air hose is detachable and usually carried under the seat.

Figs. 1 and 2 illustrate large hose couplings for garage use.

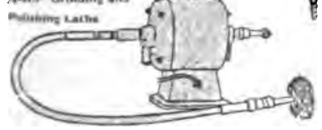
Repairing Shoe With the Westinghouse Tire Vulcanizer

Cleaning Car With a Motor-Driven Vacuum Cleaner

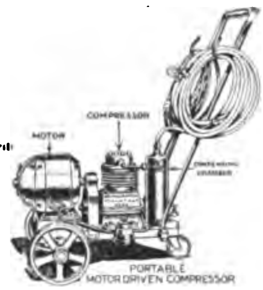
Vulcanizing Inner Tube



Portable Electric Drill



½-H.P. Grinding and Polishing Lathe



PORTABLE MOTOR DRIVEN COMPRESSOR

Air Compressors.

*A portable air compressor outfit is here shown; and can be moved to different parts of the garage.

The attachment plug is screwed into a lamp socket which operates the electric motor. This operates the air compressor which stores air into the tank. The advantages are apparent.

Compressed air for cleaning the upholstering is used in many up-to-date garages and with special connections and a vacuum tank the work is rendered easy and done quickly.

*Other electric equipments for the shop are; electric vulcanizers, portable electric drills, portable grinding and polishing lathes.

Air hose for compressed air garage work must be heavy and comes in 6 ply. Size ¼ inch (inside measurement).

For hand and portable pumps, 3/16 inch, 3 ply; 3/16, 5 ply.

**How to Determine Speed and Size Pulley to Use for Driving Air Compressors.

The speeds at which air compressors should operate is of importance and is determined by the sizes of pulleys. It should be remembered that the larger the driving pulley, the faster the compressor, (having a given size pulley) will be driven and vice versa. We give here the method of determining the pulley sizes and speeds under different conditions:

When compressor is driven direct from electric motor a 3 in. pulley should be used on the motor to keep the pulley on the compressor as small as possible. To determine the size of compressor pulley multiply the speed of the motor by the diameter of motor pulley and divide the result by the number of revolutions of the compressor:

Example—what size compressor pulley is required to drive an air compressor at 340 r. p. m. direct from an electric motor having a 3 inch pulley and running at 1700 r. p. m. $1700 \times 3 = 5100 \div 340 = 15$ inch pulley on compressor.

When it is desired to drive a compressor from a motor by means of a countershaft; to ascertain the size of countershaft pulleys, multiply the speed of the motor by the diameter of its pulley and divide by the desired speed of the countershaft, this gives the size of the driven pulley on the countershaft. Then multiply the recommended speed of the compressor by the diameter of its pulley and divide the result by the speed of the countershaft for the size of its driving pulley.

Example—It is desired to drive an air compressor, having a 9 inch pulley, at 350 r. p. m. by a motor having a 3 in. pulley and a speed of 1700 r. p. m. The compressor cannot be driven direct from the motor and a countershaft must be used. What size pulleys must the countershaft have?

$1700 \times 3 = 5100 \div 425$ (speed of countershaft) = 12 in. Size of driving pulley. $350 \times 9 = 3150 \div 425$ (speed of countershaft) = 7.4 in. The nearest commercial pulley is 8 in. Therefore an 8 in. driving pulley is used on countershaft.

When countershaft runs the same speed as compressor, then the pulley on compressor and drive pulley on countershaft, must be the same diameter, irrespective of what that diameter is, any where from 3 inches to 3 feet.

When an air compressor is driven from a line shaft without a countershaft and the size of driving pulley is required, multiply the speed of the compressor by the diameter of its pulley and divide by the speed of the line shaft.

Example—an air compressor having a 9 in. pulley is to be driven at 350 r. p. m. from a line of shafting having a speed of 450 r. p. m. What size pulley must be used on the line shaft? $350 \times 9 = 3150 \div 450 = 7$ in. Size of driving pulley on line shaft. (see also page 617.)

CHART NO. 237-A—Various Uses of Air Compressors. How to Determine Size of Pulley to Use for Driving Air Compressors. Many Uses of Electric Current in Shop and Garage.

1—Tire connection and 25′ hose	5.00
	$121.25

Size Tank To Use.

Tanks at pressure given, will inflate 35x4½ tires to 85 lbs. as shown in table.

Tank	Size	200 lbs.	180 lbs.	160 lbs.	140 lbs.
20 gal.	14x30	4 Tires	3 Tires	2 Tires	1½ Tires
32 "	16x36	6 "	5 "	4 "	3 "
40 "	16x48	9 "	8 "	6 "	4 "
50 "	16x60	12 "	10 "	8 "	6 "
65 "	18x60	15 "	13 "	10 "	8 "
80 "	18x72	19 "	17 "	13 "	10 "

After inflating tires of this size, each will have from 89 to 90 lbs. left, with which to inflate several smaller tires.

Construction of a Fabric Tire.

The carcass, which is the strength of the tire, is built up by placing several layers (4 to 7) of closely woven cotton fabric on a mandrel or core shaped like the inside of tire. The carcass is dependent upon the tread, cushion and breaker for protection.

Cotton fabric is used because it is flexible, easily permeated with rubber and best resists heat. **If too many layers of fabric were used**, it would thicken the carcass, causing it to be stiff, less flexible and inside plies would break easily and heat would be difficult to expel. Heat has a tendency to loosen the "frictioning" between the fabric plies.

The tire assembly is as follows: (1) **One layer** or **ply of fabric** is placed over core.

(2) **Bead** is formed by placing the lower edge of fabric around the bead form; hard rubber is used to form bead of a clincher tire and small wires for straight side tires.

(3) **Other layers or plies of fabric are placed, one over the other**, but before doing so, rubber is infused by pressure, into and between each layer or ply of fabric which impregnates the fabric thoroughly; **this is called "frictioning."** (4) **A cushion of ⅛″ soft gum rubber** is placed over the fabric carcass.

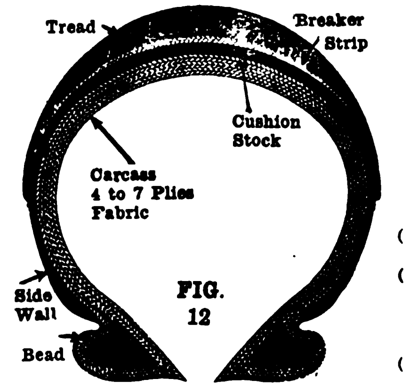

FIG. 12

(5) **Breaker-strip** is then placed over the cushion. It is made of coarse loose woven fabric and it serves to ward off attacks of sharp objects that may penetrate the tread. When a tire wears through the tread, the "breaker" is exposed.

(6) **A chaffing strip**, consisting of a strip of fabric about 2″ wide, is applied to edge of and above bead.

(7) **Then the side walls**, made of thin tough rubber (made thin to expel heat) is applied.

(8) **The tread**, made of thick tough rubber is applied last.

(9) **Then tire on forming core, is placed in an iron mold** divided into halves (see fig. 28). The part U, of this mold is placed over the part L, covering tire and fastened.

(10) **The mold with tire is then placed in a cylindrical tank** or **kettle**, or hydraulic press vulcanizer and open cured.***

(11) **Live steam is turned into this tank at a pressure of 50 to 60 lbs.**, which corresponds to about 300° F. This tank holds from 25 to 30 tires.

(12) **After curing**, tire is placed in storage to "after cure."

FIG. 28

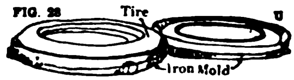

CHART NO. 237-B—Power Driven Air Compressor Outfits for Shop Use—see pages 563 and 617; how to figure size pulley to use to drive compressor. **Construction of a Fabric Tire.**

*One tight and one loose pulley. **Above Air Compressor Outfits mfgd. by Brunner Mfg. Co., Utica., N. Y.. write for catalogue. Prices quoted above not guaranteed. Subject to market conditions.

***Cured, means vulcanizing; **open cured**, is process where live steam comes in contact with the raw rubber; **dry cure**, is where steam is not in direct contact; **uncured**, is raw unvulcanized rubber.

INSTRUCTION No. 42.

TIRE REPAIRING: Construction. Tire Troubles; cause and remedy. Inner Tube Troubles; cause and remedy. Care of Tires. Vulcanizing Methods. Address of Tire Manufacturers.

Construction of Pneumatic Tires

There are two kinds of pneumatic tire constructions: the "fabric," and the "cord" construction.

In the fabric construction the carcass is made of closely woven, and **interwoven** cotton fabric, see page 564, fig. 12.

In the cord construction, the carcass is made of loosely woven cords and **not interwoven,** see page 559.

The fabric carcass type of tire can be constructed by two methods; the "full-molded" method and the "wrapped" method.

The full molded method is constructed as explained on page 564. It is built up on an iron core or mandrel and is then placed in a mold (fig. 28), which in turn is placed in a hydraulic press vulcanizer, the object of the press being to close the halves, L and U of the molds tightly. With a full molded type tire, the entire construction is **cured or vulcanized complete at one operation.**

With the wrapped tread method, the fabric carcass, side walls, cushion and breaker-strip are formed or built up in the same manner as a molded tire, but is semi-cured (half cured) in this mold. After this semi-cure operation it is **removed** from the molds (fig. 28), and the part where tread goes is buffed off and cemented with several coats of high grade vulcanizing cement. A semi-cured tread is then treated with several coats of vulcanizing cement and allowed to dry, after which tread is applied to carcass and rolled down under pressure to remove all air.

An air bag is then placed inside of the tire and entire tire is **wrapped tightly with canvas cloth strips** about 2 in. wide, then instead of putting back in the mold (fig. 28), where it was semi-cured, it is placed in a horizontal vulcanizer (large kettle) and the final cure (vulcanize) with live steam is given, after which the tire is left standing until cooled and then canvas strips are removed and tire is then laid away for a few weeks to "after cure."

A wrapped tread tire can always be distinguished by the slightly roughened surface, which is the impression from the cloth wrapping.

The advantage of the wrapped tread construction is the possibility of detecting if there are defects in the tire, as pinches or buckles, which can be determined before tread is applied, which enables the manufacturer to turn out a perfect tire. This type of tire is more expensive to manufacture.

The rubber used in making the tread and cushion stock of a tire consists of a gummy substance obtained from the milky juice of certain tropical trees, mixed with sulphur to tend to harden it and give it strength. When heated, it changes from a sticky mass resembling chewing gum, to the elastic form in which we see it in a completed tire.

The best rubber is called Para, which comes from the city of Para, near the mouth of the Amazon river. Other good rubber comes from Africa, India, Ceylon, So. America.

The white dust often seen on rubber goods is called "bloom" and is due to the sulphur in the rubber not chemically combined with it. Old tires in stock a long time accumulate considerable bloom and get hard.

**Care of Tires.

Proper inflation. Keep tires inflated to pressure recommended by the maker. Nothing ruins a tire so quickly as running it so soft that the canvas continually bends. It is almost impossible to over-inflate a tire with a hand pump.

Running a flat tire, even a short distance, is sure to be costly. Better run on the rim, very slowly and carefully, if imperatively necessary, and the distance is short.

Keep grease and oil away from your tires and tubes always. They destroy rubber.

Speedy deflation demands instant attention. Carry an extra casing and inner tube.

Don't let weight rest on deflated tires even over night.

Equalizing traction: It is important that tires of the same diameter be used on the rear wheels. Furthermore, special treads and chains should be used in pairs. If there is a variation in the diameter of the rear tires or in the traction of the wheels, the differential is caused to work whenever the car is in motion. In this way, considerable power is lost and the differential parts are unnecessarily worn.

*Alignment of wheels: It is very important that the wheels are in alignment, if out of line, the tire treads will wear, in a very short while. As usual in this case, the tire manufacturer will not guarantee or rebate, on a tire tread ruined by wheels being out of line—see "alignment of the wheels being out of line—see page 683.

Side skidding and rounding corners rapidly will cause rim cutting. Avoid running in car tracks.

Setting brakes suddenly causing the tire to drag, causes loose treads, worn treads and damages tire. Always set brakes gradually—see pages 506 and 495.

Do not drive in the ruts or bump the side of the tires against the curbing or pavements, and don't start your machine with a jump.

If one of your tires sustains a cut to the extent of exposing the fabric, an emergency band or patch should be applied at once.

Keep an odometer record of the mileage of each tire. You will find that you are getting better mileage than you would otherwise imagine.

Keep rims in good order, straight and true. Rust is destructive. Paint preserves.

*Wheels running over a fraction of an inch out of alignment cause a grinding wear on the rubber Front wheels suffer most.

**A useful and valuable booklet "Care and Repair of Tires," issued by The Firestone Tire Co. Akron, Ohio, will be sent free on request, by writing this firm. A good deal of beneficial information is contained therein, also write B. F. Goodrich Co., Akron, Ohio.

A book well worth the price of $1.50 on Tire Repairing and Vulcanizing can be had of A. L. Dyke, Pub., Granite Bldg., St. Louis, Mo.

The rims, if rusted, should be thoroughly cleaned and sandpapered, then painted with liquid graphite (common stove polish will answer). Also apply to bead of tire.

Inner tubes. Carry them in the coolest part of the car away from oil cans, and tools. The best protection, is a soft bag, well dusted with soapstone, in which the carefully folded tubes are put. See chart 238—**how to fold an inner tube.**

Unless some pressure is retained however, the tube will have a tendency to crack when again inflated, if left folded for a long time.

Before "stabling" your car at night examine your tires and remove small pieces of glass, little nails, etc., that may have become lodged in the rubber. Next day they are apt to work their way through and cause a puncture.

Spare tires should be kept in a place where they are not subjected to light, heat, or rapid changes in temperature.

Nothing will wear a tire faster than sudden locking of the rear wheels with the brakes and turning corners at considerable speed. Use your brakes with judgment and turn corners slowly.

Never allow a tire to wear until the canvas fabric becomes injured, because the wall of the tire is apt to become too thin to prevent the pressure of the inner tube from bursting through the weak portion. Remember that the strength of the tire is in the fabric. The rubber is merely a binder which unites the various layers of fabric and forms a covering over the whole.

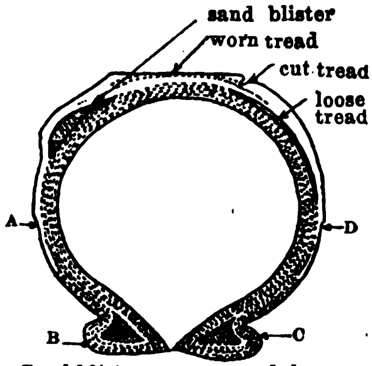
Tire Troubles; Causes and Remedy.

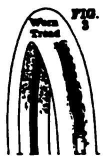
Some of the tire troubles are; stone-bruises, loose treads, sand-blisters, worn-treads, chaffed tires, rim-cuts, punctures, cuts clear through carcass, blow-outs.

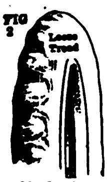
Stone bruises are caused by tire striking a stone at a high rate of speed resulting in one are all layers of fabric breaking, yet tread may not even be cut. Inner tube works into this break and a blow-out, per fig. 4, page 567, results. Tires have been known to blow-out while standing in the garage due to stone bruise. **Examine tires when off rim** and feel of the fabric, inch by inch for a weak spot, or if break is clear through, you can see it, per fig. 5.

A temporary repair can be made by using "inner" and "outer" shoes, per page 568, but it is advisable to repair as per page 575, as a blow-out may occur even with this "inner shoe" covering the weak spot.

The cord tire is not subject to stone bruises because the cords are not inter-woven, or cross woven like a fabric tire and instead of breaking, they give.







Sand-blisters are caused by a small hole or cut in tread through which sand and dirt work under the tire causing it to pucker up and will result in a loose tread if not closed up. The hole through which the sand worked into and under tread may be several inches away. **Close it up** with a plastic substance called "tire dough" **or vulcanize it.** See page 570; "sand-blister repair."

Loose treads result from running a tire not properly inflated, or from moisture getting under tread through a cut in the tread, or from a defect in the tire where the rubber compound is poor and does not adhere, and from setting brakes suddenly, see page 565.

Loose treads can be repaired, unless the tread is loose about 1/3 of the way, in this instance a new tread must be applied—providing the fabric carcass is not cut—if so, repair it first—and providing layers or plies of fabric in the carcass are solid and are not separated.

The molded type of tire is more subject to loose treads than the wrapped tread construction.

Worn treads in center, or slightly to the side of tire, usually result from driving in street car tracks, wheels being out of line (usually on the front), due to steering knuckles bent or steering apparatus out of order. See page 683.

Chaffed tires, usually worn on the side, result from driving close to curbstones, in street car tracks, ruts, etc. This permits water to rot the fabric. **Repair** by rebuilding the side walls and vulcanize.

Rim cuts are due to running tire flat after a puncture, or running on the rim which damages the curve in rim and which cuts the tire at the rim just above the bead. Improper inflation is also a common cause, this permits the edge of the rim to cut the bead when deflated tire receives a heavy jar. **Rim cuts can be repaired** if cut in only two or three short places, but if cut at sections all around tire, then it cannot be repaired.

Punctures through tread and carcass, if small, will not cause damage to carcass but the tread should be closed by vulcanizing with the small vulcanizer while tire is inflated on car, or some kind of plastic material as "tire dough" stuffed into it to keep water and sand out.

Where tires are cut through the carcass, this can be repaired if cut does not extend too long and the plies of fabric are not separated. It is repaired the same as a blow-out repair, page 575.

Retreading.

Retreading: It is no easy matter to form a correct judgment about any tire with regard to retreading. In some instances a tire case may appear to be sound and yet prove to have stone bruises in the carcass on inside examination, or the layers of fabric may be separated from each other. On the other hand, there are undoubtedly covers condemned because of local damages, which properly examined, would be worth retreading.

The age of the tire and condition of fabric and cost of retread will determine if worth while to retread. The strength of the tire is in the carcass. The rubber tread is merely a protection.

Therefore the condition of the carcass must be determined when deciding as to retreading. There are three conditions to note; (1)—is the carcass badly cut in several places—if so, don't retread or repair; (2)—are all the layers of fabric of carcass together and not separated; sometimes these fabric layers separate and pucker up due to improper adhesion in manufacture, or water getting under tread and into the carcass; (3)—is tire rim cut badly.

Blow-Outs.

Greatest tire trouble—blow outs. A blow out is simply a hole blown through the car-

Fig. 4—When a blow out occurs it always leaves a weak spot.

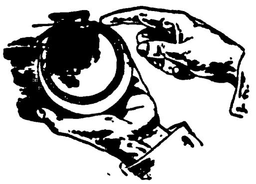


Fig. 5—The tire is made thin here for a purpose.

cass or fabric. **There are two classes of blow outs**; those occurring near the rim and those in the tread or on the side.

We will designate the first mentioned as a **"rim blow out,"** and the latter as a **"tread blow out."** Wherever a blow out occurs, that spot always remains weak, because the fabric can never be joined again. but can be repaired, see page 566.

Cause of rim blow outs: A tire is made thin at the point shown in the illustration (fig. 5), near the rim, for a purpose. Very nearly all the "bend" and "give" is at this point. If it was made thick and heavy, it would break; therefore, it must be thin and flexible.

If you were to take a wire and bend it quick and often it would get hot and break—same with this bending point of the tire near the bead—especially if the tire is not properly inflated.

Cause of inside breaks in fabric are due to stone-bruises and running tire improperly inflated—see page 566.

If you were to take a deck of cards and bend them back and forth, it would be noticed that the bottom cards would receive most of the sawing strain—just so with the several plies of fabric when tire is not properly inflated.

Therefore keep tire inflated and many of the tire troubles will be avoided.

A tire may look sufficiently inflated and yet have only 40 pounds of air in it, when it should have seventy. No amount of kicking, feeling or looking will tell; the only sure way to tell is to have a reliable air gauge—see fig. 14, page 568.

Cause of tread blow outs are due to cuts on tread and stone-bruises. Cuts and jabs ou the tread of tires permit dampness, oil or dust to get between the rubber and the fabric, which soon rots and weakens it.

Inasmuch as the fabric must sustain the air pressure, a weak place in the fabric **is enlarged by the pressure** and a blow out is the result—and once a blow out occurs, it can never be repaired so that it will be strong as it was at first.

Therefore repair cuts in the tread and examine tires for internal fabric cuts caused **by stone-bruises,** when tire is off wheel.

External cuts in the tread can be vulcanized while inflated and on wheel—with the small vulcanizer shown on pages 570, 573.

A temporary repair of a blow out or an internal fabric cut, or weak places in the carcass can be **temporarily** protected by inserting an **inner shoe** between inner tube and carcass and an **outer-shoe** over the tread, per fig. 11 and 9, page 568. The defect should be repaired **as soon as possible** however, as a cut in the fabric will soon work larger and cause a blow out from rim to rim.

***How to get additional mileage or service out of old tires:** Very near every motorist has one or more old tires which is of no use. Many will be interested in knowing that these old tires can be made serviceable again by placing inner shoes inside of the tire, covering the weak spots or holes and then placing reliners inside of the tire over those reinforced places (see fig. 17, page 568).

**Inner Tube Repairs—Causes of Trouble.

Punctures may result from a puncture through tire from outside, or it may result from rough places inside of case, as soapstone balls, etc.—(see page 569), or from tube being pinched.

Tube pinching. Referring to the most common causes of damage to inner tubes, attention is called to the manner in which many tubes are pinched beneath the bead of tire or beneath the staybolts—(see fig. 1, page 568, also "stone-bruises," page 566).

The valve may leak. It sometimes happens that a tire becomes deflated because of a leaking valve, and the condition may easily be supposed to be due to a puncture. **If no visible sign that the tire has been penetrated is discovered,** put a few drops of water in the valve stem. Bubbles will indicate a leak, or the valve can be tested as shown in fig. 3, page 568.

If such is the case, the valve parts should be tightened with the notched cap (B) of the valve stem inserted in the valve and used as a wrench. (See fig. 2, page 568).

If this does not remedy the trouble, entire new valve parts (A) page 550 should be put in place. Every repair kit is supplied with them and they should be kept in the kit constantly, as well as caps (B).

Method of Repairing Inner Tube.

In this case the inner tube is supposed to be punctured, but the casing practically uninjured, as in the case of puncture by a nail or tack.

First of all, satisfy yourself that the tack or nail is not sticking in the casing, for if it is, your repaired tube will be punctured again before you have gone 1,000 feet. Having done this, the inner tube may be removed (wholly or in part, as may be necessary) and either repaired or replaced.

*Reliners should never be placed in new tires. They are detrimental to tire and tube and are used only for old tires ready to throw away or where additional mileage is desired. **See page 574 for prices usually charged for inner tube repair work.

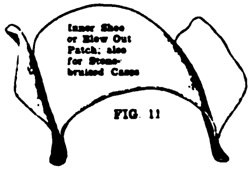

Fig. 11—Inner shoe, to go on inside of tire to protect fabric cuts, breaks or weak places due to small blow outs or stone-bruises or rough spots and also a protection to rim cuts. Made of 3-ply fabric with wings, to go under the rim.

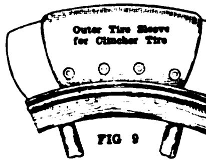

Figs. 9, 9A—Outer shoe, to be placed temporarily on outside of tire when cut or damaged until vulcanized. Note lower part fits under rim for clincher, and under tire for straight side.

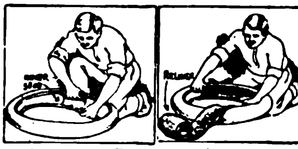

Fig. 16—Insert an inner shoe for small blowouts or weak places in tires.

Fig. 17—For bad cuts or large blow outs, or when using an old or worn out tire. First insert inner shoes over the holes, then reliner in inside of tire as shown.

Reliners are hard on inner tubes and are not advisable to use in new tires—only for temporary repair of old tires.

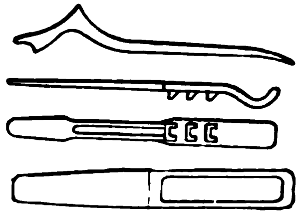

Fig. 12.—A set of tire tools suitable for attaching and detaching "clincher" tires on one-piece rims. In addition to these tools a good heavy hammer and a reliable jack, come in handy as well.

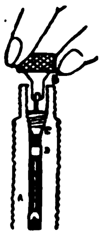

Fig. 2.

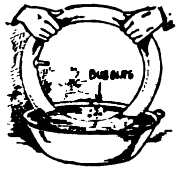

Fig. 4.

Fig. 2—To remove "inner-valve" when tube is to be deflated—use notched end of "valve cap" B.

Fig. 4—To test inner-tube for leak; partially inflate tube and place in pan of water; air bubbles will appear at leak. Mark leaks with indelible pencil. See page 735, fig. 20 for a testing tank for shop.

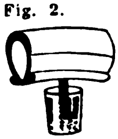

Fig. 3.

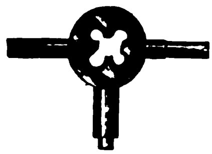

Fig. 5

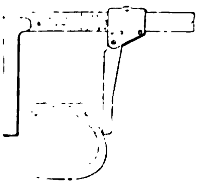
***Fig. 3—To test inner-valve for leak; inflate tube; place end of valve, with valve-cap removed, in glass of water—if bubbles appear inner-valve leaks. Put in a new one.**

Fig. 5 — Four-in-one valve tool; die for re-cutting threads for valve cap; tap for inner-valve threads; inner valve remover.



How to operate the Goodrich tire gauge: Set the movable arm at the point where the caliper will just fit over the tire at the top. Note the point of register on "size scale of tire" and move the arm to the corresponding mark on "load scale on ground."

Now test the tire at the bottom where the load rests on it. If the caliper just touches the sides the tire is inflated properly. If tire is too much flattened to permit the caliper to slip over it, inflate the tire until tire under load is just as wide as space between arms. Above shows tire underinflated.

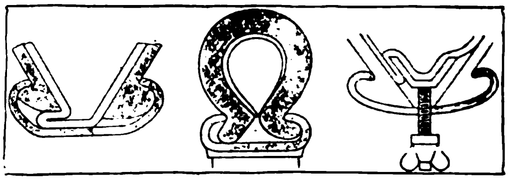


Fig. 1—Showing how the inner-tube may be pinched between the bead and casing; between the two beads, or bead and lug.

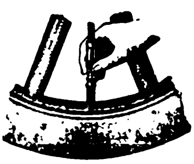

Fig. 14.

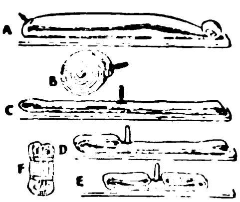

Fig. 14: Twitchell air gage is placed over the valve stem and indicates pounds pressure in tire.

Fig. 7, A to F: To fold an inner tube, remove "inner-valve" per fig. 2, then roll slowly per A and B to exclude air. Then lay flat and fold per C, D, E and F. A flannel bag is suitable for carrying extra tubes in.

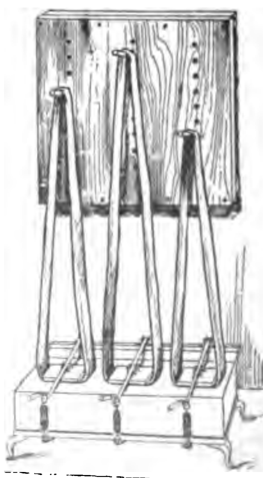

Fig. 21—A rack for vulcanizing different size tubes. This device can be used in connection with the small tube vulcanizers.

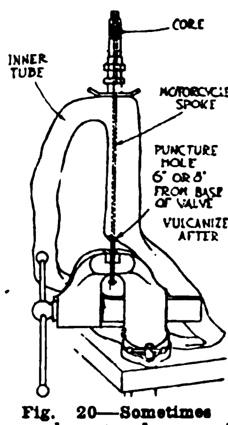

Fig. 20—Sometimes inner-valve core becomes immovable from stem. Diagram explains how to remove.

CHART NO. 238—Miscellaneous Tire Repairs and Accessories. Testing Inner Tubes for Leaks. How to Properly Fold an Inner Tube. Tire Air Pressure Gauge. Inner and Outer Shoes.

To test base of valve for leak, submerge valve part of tube in water, with tube partially inflated, per fig. 4

When on the road it is much simpler to put in a new tube; and it is best to have always at hand three spare tubes—one for the forward and two for the rear tires. An inner tube properly vulcanized is as good as new, but it is much easier to make the repair at home. **Do not carry these tubes in the tool box** where they are liable to be bruised or otherwise injured.

There are two methods of repairing an inner tube; by **cemeting** a patch over the puncture and by **vulcanizing.** The cement patch does not hold and will leak in time; therefore, the vulcanizing of the tube, as shown in charts 239 and 240, will make a permanent repair. The best plan would be to insert a new tube and vulcanize the damaged one later.

Cementing a Patch.

If a cement patch is necessary, owing to the absence of a vulcanizer, then proceed as follows: **Select a patch of the right size;** that is, large enough to extend three-fourths of an inch or an inch beyond the puncture in each direction. Wipe off every trace of moisture or bloom and roughen with emery cloth the **surfaces** to be joined. Apply two coats of cement to the tube surface and to the patch, removing with the fingers all superflous cement; the less of it there is, the quicker the repair.

Allow the cement to dry until it adheres strongly to the fingers (five minutes at least will be needed), then, and not until then, apply the patch; compress strongly and look carefully to see that the edges of the patch do not loosen.

Before putting back the tire, assure yourself that the cause of the puncture is removed, as a nail or tack or rough spot inside of casing, else tube will puncture again.

Note.—Never try to join two surfaces while **they are still damp,** for rubber cement joints are of no value unless everything is dry. Never apply friction fabric to an inner tube, but always a patch of pure caoutchouc. Friction fabric is not air-tight.

Even though a sound tube has been inserted on the road, the punctured tube should be mended promptly to be ready for another emergency. There is scarcely a limit to the number of repairs a tube will bear, but patches applied with cement cannot safely be considered permanent repairs. **It is a paying investment to make vulcanized repairs** as opportunities present themselves.

When a patch becomes loose. It will sometimes happen that a tire will become partially or even entirely deflated without apparent cause—that is, without any nail or other puncturing instrument being visible. If you have had experience with occurrences of the kind, you will immediately suspect a loosened patch and proceed to verify your suspicions. Partly inflate the tire and your ear will tell you whereabouts the leak is. Only remove as much of the casing as will enable you to conveniently attack the job. You will very likely find that, although the air has burrowed a small channel between the patch and the tube in one place, other portions of the patch are holding on tenaciously. Why an inner tube patch does not stick all over alike, is what no one ever could understand.

A drop of gasoline applied with care does wonders in persuading the patch to peel off, and afterward in cleaning the surface of the tube; but do not apply the solution until you have well roughened the place with sandpaper. Put the old patch away for future use, and apply a fresh patch, two coats of solution, spread on thinly, and well rubbed in, especially the first (you cannot rub the second coat hard, or the lot peels off); squeeze the patch and tube together as hard as possible with finger and thumb, beginning in the center of the patch and working out to the edges. You may hold a block of wood under the tube and beat the patch with a hammer if preferred, but go gently. One motorist belabors his patches unmercifully and, says they never come off. Judicious beating does no harm, and screwing up in the vise between two pieces of wood, and leaving all night also works wonders.

Inner Tube Pointers.

How to carry extra inner tubes. Deflate tube and fold, as shown in fig. 7, chart 238, powder the tube with a generous amount of talcum powder, then wrap in a piece of canton flannel or cheesecloth and pack in a small wood box with a sliding top; this will protect tube indefinitely.

If the car is equipped with smaller tires on the front wheels than on the rear wheels, carry an extra tube for each size.

The cross sections of inner tubes are made a little smaller than the normal air space inside of the cases. It is not, therefore, advisable to use a 4½ inch tube in a 4 inch case. This usually wrinkles and creases the rubber, with bad results. Do not use a 4 inch tube in a 4½ inch case for any length of time. When this is done the rubber is required to stretch too much and the effect of heat and action due to displacement of air in the tire quickly uses up the nerve and life of the tube.

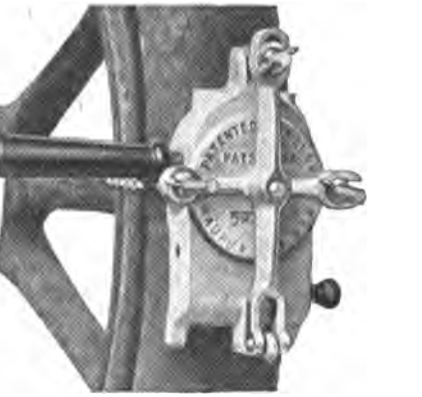
Lubrication is most important to the conservation of the tube, but it is a matter that is given least attention. Practically all tire manufacturers treat the inside of cases with a white solution to prevent **tubes from** *sticking to the casing, and to reduce the frictional wear—a good lubricant, however, should also be used.

Some owners neglect dusting soapstone inside of the case when changing a tube, others use the soapstone so sparingly that it does but little, if any, good, or they may use so much that it does more harm than good. If a quantity of it be dumped into the case it will collect at one point, and during the hot weather will heat up to such an extent as to burn the rubber of the tube, making it very thin, brittle and lifeless; this can be recognized by the honeycombed appearance. **Soapstone is the lubricant most used for tires** and it is quite satisfactory, but not lasting; therefore a fresh supply should be put into the tires at least two or three times during the season. **Powdered mica** has proven a more durable lubricant than soapstone and quite as effective as graphite, as well as more pleasant to handle. The lubricant should be applied with a soft rag and rubbed into the pores of the tube, also on the fabric all around the case.

Life of an inner tube—if good rubber, should last for two years. As tube grows older the rubber becomes hard and porous and finally reaches the "past repair" stage, which is noticeable by constant slow leaks. New tubes are then advisable.

*__A gray inner tube__ is not colored. The best gray tubes use pure Para gum with sulphur, to give it strength. This sulphur causes a "bloom" or white gray dust which gives it the color.

A red inner tube uses a dye to give it color and instead of sulphur, antimony is used, which will stand a greater amount of heat. Heat causes rubber to harden and crack. Gray tubes stick to cases, red tubes will not stick. Therefore, the advantage of a good red tube is in these two points.

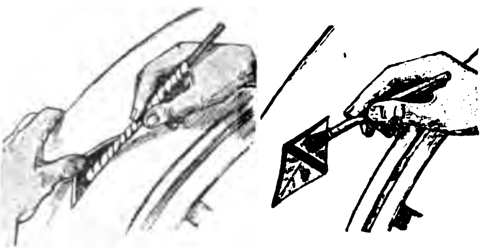


The tourists gasoline or alcohol vulcanizer, vulcanizing the outer casing.

To Vulcanize Tire.

To prepare casing and patch—thoroughly cleanse the cut or tear by using sand paper or a pocket knife and wash same perfectly clean with a rag, using gasoline. Cleanse a layer of repair gum with gasoline, insert it in the cut and trim it flush with the casing. If the injury is void of material, then build up even with casing by cleaning each layer of repair gum with gasoline and firmly pressing into place.

Clean with gasoline.



Get all dirt out, then cut old rubber away and give hole another cleaning.

To apply vulcanizer: Firmly clamp the center of the vulcanizer directly over the prepared patch, using care to have the patch centrally located against the face of the vulcanizer as illustrated. Before applying the vulcanizer, the face of same may be dusted with soapstone or talcum powder or a cake of ordinary soap can be rubbed against it to prevent repair gum from sticking.

To Vulcanize Inner Tube.

Preparation of tube and patch—to repair a punctured tube. Clean the spot around the puncture about two inches in diameter with emery paper, then wash off clean with gasoline. Cut sufficient repair rubber to cover the puncture and dampen the surface of the rubber to be applied to tube with gasoline, allowing it to dry thoroughly. Then apply the repair rubber to the tube directly over the puncture, as illustrated in fig. 1.

Figure One

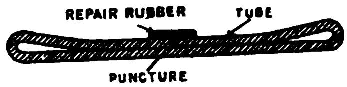


Figure Two

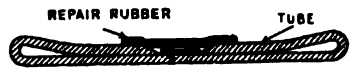

To repair a rent, pinched or torn tube—shear off damaged part to a beveled edge and follow cleaning and washing instructions as above. A piece of repair rubber the exact size and shape of the hole must be placed in position and another piece of repair rubber larger over all than the hole must be placed on the damaged part; as illustrated in fig. 2.

Care must be taken that the tube is thoroughly cleaned with emery paper and gasoline; and that the surface of the rubber applied to the tube is washed with gasoline and allowed to dry.

To apply vulcanizer—clamp vulcanizer directly over the prepared tube and fasten securely and uniformly with the thumb screws, being careful to have the patch centralized beneath the vulcanizer, as illustrated in fig. 3.

Operation of tourist's vulcanizer: After preparing tube as instructed, attach vulcanizer as shown. Stand vulcanizer on bench, running-board, or floor. Remove the cylindrial lamp, and pour the gasoline or alcohol on it from the measure which is furnished. Insert lamp into vulcanizer and light it. After lamp goes out, which will be in about ten minutes let the vulcanizer cool a few minutes and the repair is done.

When vulcanizing a casing clamp the vulcanizer in place with the chain furnished with it. Heat the vulcanizer with the lamp as above. There is no exposed blaze and no chance to spill burning fuel so that it is perfectly safe to vulcanize a tire while inflated on the wheel.

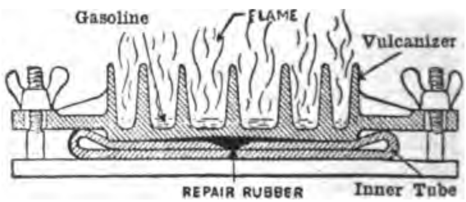

Fig. 3—Showing inner tube being vulcanized and how the gasoline or alcohol heats the vulcanizer on another type of gasoline vulcanizer.

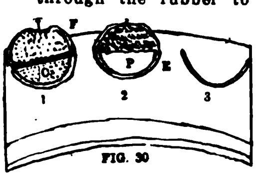
*Repairing Sand Blisters.

(1) Cut half way around the blister, cutting through the rubber to canvas (C) and leave rubber attached on the side nearest tread of tire. Turn back the flap (F) thus formed and remove all dirt; then clean and cement as directed for casing cuts per above.



(2) Cut a strip of Para rubber as wide as the rubber on the tire is thick and stick on edge of cut (E). Then cut a thin sheet of Para, the exact size of the canvas and roll back in place and stick it down tightly (P).

(3) Shows repair after vulcanizing. Be sure to vulcanize hole where dirt entered and caused the blister, it may be a foot away—vulcanize as per instructions for small cuts,—see also pages 570, 573.

CHART NO. 239—A Portable Vulcanizer for Vulcanizing Small Cuts on Tires and Inner Tubes.

A tire pump is an excellent bellows for blowing dirt out of a cut for a repair to be vulcanized. A sheet of waxed paper should be placed between vulcanizer and tire to prevent sticking to hot iron.

***To repair a section of a tire where tread is loose:** Cut through the tread, clean under side of tread and canvas thoroughly. Apply two or three coats of cement; when dry replace tread, wrap with tape, per fig. 25, page 575 (this is the wrapped method of vulcanizing)—then cure with inside and outside heaters as instructed for blow outs, figs. 25, 26, page 575.

Valve Spreaders.

It is essential that tubes be equipped with valves having the correct type of spreader. See figs. 3, 4 and 6, (L), chart 235. Fig. 4 and 6 would interchange because they have angular shaped sides whereas fig. 3, chart 235 and fig. 1, chart 236-AA have curved sides. Most companies have in the past furnished tubes with especially equipped valves for clincher cases, another type for Q. D. clincher cases, and still another type for straight-side cases. The clincher valve spreader will not properly lock the Q. D. clincher beads on a Q. D. clincher rim, nor the straight-side type of tire on a straight-side rim. The valve equipped with a straight-side spreader will lock the beads on a clincher rim or a Q. D. clincher rim, but on account of difference in width and shape may damage fabric of the case.

The purpose of a spreader is to keep inner tube from being pinched at the stem hole in the rim, also to act as a protection in case dust cap is screwed down too tight, which is very often the case and inner tube is partly pulled or pinched in rim hole.

Spreaders are not absolutely necessary, but as stated above, they greatly lessen the chances of tubes "going bad" around the valve stem, before the rest of the tube has given all the service that has been built into it.

The difference in the spreaders is necessary, due to the difference in space between the beads as they set on the rim.

Repair of Tires.

Temporary tube repairs can be made by the use of cemented or self-curing patches which are easily applied. However, as patches are unreliable, owing to the fact that they often come off when the tire heats from running, it is much better to make permanent repairs in the first place by vulcanizing.

A small vulcanizer per page 570 and 572 can be used for vulcanizing inner tubes, which is a very simple operation. The tube is cleaned around the puncture and coated with vulcanizing cement. Then a piece of raw rubber, the same as that from which tires are made, is placed over the puncture. The vulcanizer is applied as shown in the illustrations, chart 239, and heat is applied for about fifteen minutes,—dependent on the kind of vulcanizer that is used, and the thickness of the rubber being vulcanized. (see also page 572).

For small cuts, sand blisters, etc. on tires, this vulcanizer will also answer, but for blow-outs and large cuts in tires a larger vulcanizer is necessary, see pages 574, 610.

By giving cuts on casings a little attention now and then, tire mileage can easily be doubled or trebled. Small cuts, neglected, admit dirt and water to rot in the fabric until a blowout occurs that ruins both tube and casing. The only sure remedy is vulcanization. See pages 570 and 573 for repairing cuts in casings. This can be done while tire is on wheel inflated.

What is Vulcanization?

It is the process of cooking or curing raw Para gum. Exactly as in baking a loaf of bread, the best results can only be obtained when the proper amount of heat is used.

The temperature ranges form 250 to 300°; about 265° being considered best.

It requires 15 to 20 minutes to vulcanize a layer of Para $\frac{1}{16}$" thick at 265° temperature and 5 additional minutes for each additional $\frac{1}{16}$".

It is immaterial whether vulcanizer be heated by electricity, gas, gasoline or steam. The idea is to keep the vulcanizing surface at a steady and proper degree of heat. **See page 574 and 610 for vulcanizing outfits, tire repair tools, etc.**

Tire Paint.

Tire paint for painting the inside and outside of tires is mixed as follows to make 1 gallon: Mix 1 quart of gasoline and 5 lbs. of whitening, stirring until thoroughly mixed. Add 1 quart of No. 1043 Firestone cold patch cement (or any other cold patch cement) gradually and stir until mixed.

The solution is applied with a brush and leaves a white surface which will not crack due to the elasticity of the cement.

*Motorist's and Shop Vulcanizers.

There are several standard types of motorists' vulcanizers available. They are designed with a view to supplying machines that are adapted to the most convenient sources of heat. On the road, gasoline is always available, therefore for tube work and small casing repairs, a gasoline heated vulcanizer is handiest. Where there are electric lights, they naturally suggest the cleanest and handiest heat. Motorists who have city lighting current in their garages prefer the electric vulcanizer on account of its convenience and large capacity. Most of the work is done at home and an electric vulcanizer, which has its heat controlled automatically and maintained as long as desired (an essential feature), has the advantage that by leaving it on a tire as long as is necessary, the thickest tread repair can be cured clear through as well as a superficial repair. Successive repairs can be made without loss of time as vulcanizer can be moved from one to another.

The charts following will clearly explain the method of tire repairing. It is the writer's intention to deal with the vulcanizing subject only in an elementary way. To those interested in the tire repair business I would advise writing to C. A. Shaler Co., 22 Jefferson St., Waupun, Wis., for a copy of their very complete book, "How to Open a Tire Repair Shop." and "Care and Repair of Tires." Also Williams Fdry. & Machine Co., Akron, O.

*See also page 610.

Addresses of Tire Manufacturers.

Firestone Tire and Rubber Co., Akron, Ohio.

Inner Tube Vulcanizing Repairs.

Inner Tube Punctures.

Clean the tube thoroughly with gasoline and coarse sandpaper—see page 570. Cement the edges of the hole and apply a thin layer of cement. Let the cement dry.

If a small hole, fill even with the surface of the tube with layers of Para rubber cut the size of the hole. Cut a patch of Para one-eighth inch larger than the hole or puncture and apply over same. Then cut another patch ⅛ inch larger than hole and apply over the first. Cover with waxed paper and apply vulcanizer.

Fig. 1—Repairing tube puncture.

Edges of punctures or small holes should be bevelled with scissors to make a larger uniting surface and provide room for the new material. Repairs of this sort are to be **vulcanized for fifteen or twenty minutes at 265 degrees.**

Inner Tube Cuts and Tears.

Clean **as directed,** both inside and outside of tube; coat edges of cut and inside and outside of tube with cement and let dry.

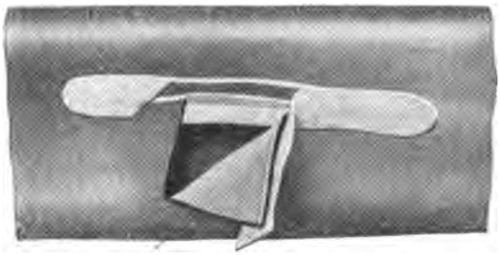


Fig. 2—Repairing slit in tube.

Cut a strip of Para rubber as wide as tube is thick, and stick on edge of cut; cut a strip one-half inch wide, place inside of tube under tear, bring edges of tear together and stick them down to this strip. (The use of semi-cured stock for the inside patch is preferable, as it obviates the use of paper inside the tube). Apply another strip of Para rubber, one-half inch wide on the outside of the tear. **Vulcanize for twenty-five minutes.** Cover the repair with waxed paper before vulcanizing.

Blowouts in Tubes.

When mending large, irregular bursts or blowouts in which a piece of rubber has been blown out

Fig. 3—Repairing tube blowout.

of the tube, the best method is to trim down to a clean, solid surface, making the hole somewhat regular in shape. The hole may be filled with layers of Para rubber cut to fit.

Inner Tube Splices.

It often happens that, when a tube is badly torn, it is easier to cut out a section and replace it with a new piece of tube. In making repairs of this kind be very careful not to alter the original length of the tube.

Clean the outside of one end of the tube for about four inches. Fold back the other end, turning the tube inside out, and clean for the same distance. Apply at least three coats of cement to each end. A repair of this sort requires a considerable amount of cement if no Para rubber is used because the adhesiveness of the joint depends upon the cement alone. A narrow strip of Para between the two tubes will add to the strength of the joint. Butt the open end against the folded end and telescope the latter over it. **Vulcanize in three operations,** the first twenty minutes' duration; the last two, fifteen minutes each. A block should be used underneath tube, to prevent pinching the edges of the tube. Vulcanizer is placed on top.

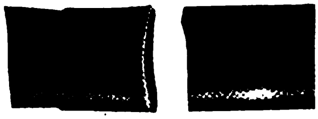

Fig. 4—Splicing an inner tube; showing tube ready to lap.

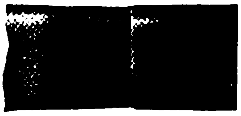

Fig. 4A—Tube after lapping.

Valve Stem Seat Repair.

Select a good place on the tube, clean a space about four by two and one-half inches and cut a hole about one-fourth inch in diameter. Remove parts from the valve stem and stretch the hole in tube over the base of valve stem. Push the stem clear through into the tube. It is to be kept inside and away from the repair until after vulcanization.

Cement entire clean surface around the hole in the usual manner. Cut an oval or diamond-shaped piece of Para about two by three inches, having hole in center to correspond with the hole in the tube. Roll it down on tube so that both holes register. Cover with a layer of blowout canvas of same size and shape. Cover all with another layer of Para rubber one-quarter inch larger all around than the first. **Vulcanize forty minutes.** Shake valve stem on inside of tube to the vicinity of the hole and force it through the opening until the base rests against the inside of the tube, then slip clamp disk (S-T) and spreader (L) —fig. 6, page 550—over valve stem and fasten them securely with lock nut (P).

Fig. 6—Valve stem seat repair.

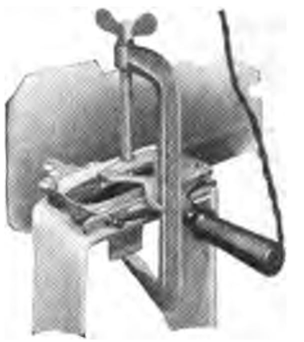

Fig. 7—The electric vulcanizer is connected to lamp socket.

Pointers When Vulcanizing Inner Tube With Steam Vulcanizer.

Time required for vulcanization is determined by the depth of the new material inserted, and not by the size or area of the repair. The following is based upon the maintenance of a uniform steam pressure of 45 pounds.

If tube is in a very much worn condition, place a piece of rubber tubing larger than the pad, under the pad, and vulcanize at a lower steam pressure and more slowly. With a steam pressure of 45 pounds:

For tubes 1-16 in. thick, vulcanize for 7 minutes.
For tubes 1-12 in. thick, vulcanize for 8 minutes.
For tubes 1-10 in. thick, vulcanize for 10 minutes.
For tubes 1- 8 in. thick, vulcanize for 13 minutes.

How to test a repair—test the part vulcanized by pressing the thumb nail into it. If it is responsive and elastic to the touch and resembles the rest of the tube in this respect, it is perfectly vulcanized. **If, however, it clearly retains the mark of the nail it is under vulcanized** and should again be placed in the vulcanizer and given a longer heat. It is best to add **time, not temperature.**

CHART NO. 240—Repairing an Inner Tube with the Shaler Electric Vulcanizer.

Troubles Which Necessitate Tire Repairs.

As stated on pages 566, 567, tire troubles are due to external and internal causes.

Due to external causes:

(1) **Tread cuts** which permit dirt to work under tread and cause "loose treads" and "sand-blisters." The moisture also rots the fabric and weakens it.

(2) **Cuts clear through tread and carcass. When** a cut is made through tread and carcass it is a perfect cut, but if blown-out the edges are ragged.

(3) **Fabric broken and weakened inside, due to striking a stone on tread of tire.**

Due to internal causes:

(1) **Blow-outs** are the result of surface or tread cuts. The admission of moisture caused fabric to rotten and pressure of tube blew through the weakened place with a loud report.

The blow-out is also frequently due to a "stone-bruise" as explained on page 566.

(2) **Broken back** is a serious and common injury and is the result of insufficient inflation—see page 567. The layers of fabric separate—this might be termed a "fabric separation."

Fig. 1

Fig. 2

Fig. 3

Fig. 4

Importance of Repairing Slight Cuts on Tires.

A set of tires should be gone over at least once every two weeks and the cuts in the treads of the casings sealed up by vulcanizing them. This can be done with tire inflated and on wheel. In this way deterioration of the fabric is prevented and the tires will give a mileage three times as great as that usually given.

Figure 1 shows a tire in which there is a small cut and a "sand-blister" or pocket. If not repaired at once, sand, dirt and water will be forced into it and rot the fabric until it becomes so weakened the inner tube will blow out through it and ruin the casing.

Figures 2 and 3 show the gash being cleaned and filled with new, live Para rubber (see also page 570).

Figure 4 shows the portable electric vulcanizer in place on the tire. Note that it has not been necessary to remove the tire from the rim. The vulcanizer is left in the position shown, for thirty minutes.

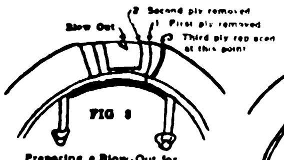
Above instructions cover the external repairs of "tread cuts," "sand-blisters," slight "loose treads."

Instructions for repairing blow-outs and internal troubles, see below and page 575.

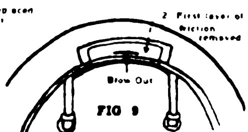
Internal and External Tire Repairs—Sectional Method.

There are two methods for reinforcing and building up tires for internal repairs; the "wrapped tread" method and the "sectional" method.

With "wrapped tread" method as explained on page 575, the tire is built up or reinforced from the inside, whereas with the "sectional" method it is built up from the inside and outside.



Preparing a Blow-Out for Rebuilding



Repairing Side Wall Blow-Out

Explanation of a Sectional Repair.

Fig. 8 illustrates how a blow-out is prepared for reinforcing and building up by the "sectional" method. Note how each layer of fabric is "stepped off." For example, there may be four layers of friction duck (canvas fabric) in the carcass. To proceed, the tread stock is cut down with knife (page 610). The first cut made (fig. 8) goes over each bead and all fabric within these limits is removed. The second cut does not go over the bead but falls inside and borders the first cut by about one inch. This removes two ply of canvas and reverse process, or building up, replaces this canvas, "breaking joints" as a mason breaks joints in stone or brick setting, and the final layer of fabric adds one ply to the original strength. The casing is then reinforced with one layer of canvas on the inside and the total strength, or four ply, has been restored.

Fig. 9 shows a side-wall blow-out in the process of repair. The same principle of stepping off and reinforcing is used, and this "stepping off" is one of the most important points to observe in making good tire repairs.

Sectional Vulcanizing.

The best method for vulcanizing blow-outs or rebuilt repairs is with a steam vulcanizer per pages 574 and 610.

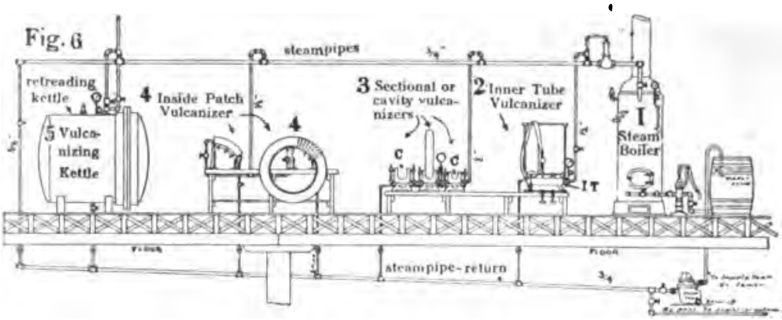
Where the blow-outs are on tread, after repairing, the tire is placed in the sectional or cavity mold (3) fig. 6, page 574 to be vulcanized or cured, and is held down by a clamp (C) fig. 30, page 610. This vulcanizes both inside and outside.

Where the blow-out is on the side-wall, or for a rim cut repair, it is necessary to insert an "air bag" per fig. 29, page 574. Then the bead mold is placed over tire and entire repair cured at one operation.

Where inside repairs only are cured, or where tire is to be dried out before vulcanizing, the "inside patch vulcanizer," at (4), fig. 6, page 574 is suitable.

CHART NO. 240-A—Troubles Which Necessitate Tire Repairs. Importance of Repairing Slight Cuts on Tires. Internal and External Tire Repairs. Example of the Sectional Method of Repair.

Don't try to use so called "self-curing" gum or old rubber—it will not vulcanize.



Example of a Steam Vulcanizing Plant.

Vulcanizers.

Steam vulcanizers are used in the larger repair shops. The steam is generated in a boiler from heat produced by almost any fuel which will heat, as wood, coal, gas, gasoline.

Electric vulcanizers, per pages 572 and 610, are suitable for small shops and garages or home work and especially desirable for inner tube work.

The vulcanizing outfit per fig. 6 consists of: (1) boiler; (2) inner tube vulcanizer. The steam passes through the iron plate (I T) and part of tube to be vulcanized is placed on this plate and other part hangs over the rack above it; **(3) sectional molds, (O, fig. 6), called cavity molds.** They are used to vulcanize the inside and outside of the tire in sections. These molds (O) are made to take different size tires. See fig. 29 and note a bead mold is placed over tire when it is in the cavity mold (O). These bead molds are made for clincher or straight side beads.

The air bag, shown in fig. 29, is placed in the tire and blown up to a pressure of about 50 lbs. to hold it in shape when being vulcanized in the cavity mold O, fig. 6. Steam passes through the cavity mold; **(4) *inside patch vulcanizer** consists of an iron core shaped like the inside of tire, through which the steam passes. The tire is placed over this core when only inside repairs are being made; **(5) vulcanizing kettle** is used in rebuilding or retreading tires—see page 564 explaining the process of constructing a tire. This is used only for very large shops.

A small steam vulcanizer using gasoline to generate steam is shown in fig. 2. Note that instead of a cavity mold, as per O, fig. 6, an "outside casing form" is used for outside vulcanizing, and an "inside casing mandrel," simlar to "inside vulcanizer" (4) fig. 6 is used for inside repairs. Steam passes through each of these devices. The inner tube plate, through which steam passes is shown in fig. 2, just above the boiler.

Prices For Tire Repair Work.

Section repairs, two to six inches on tires 3", $3.00; 3½", $3.50; 4", $4.00; 4½", $4.75; 5", $6.75. When repairs are over 6 inches add from $1.25 to $5.50.

Inner tube repairs; punctures (single) 50c; each additional puncture in same tube 25c; blow-out in tube, 75c; valve base, 75c; new valve $1.00.

Taking rim off wheel and replacing 25c. Taking casing off rim and replacing 25c.

Retreading: The different tire manufacturers supply treads which cover the entire tire and price varies. This work is seldom done only in large repair shops.

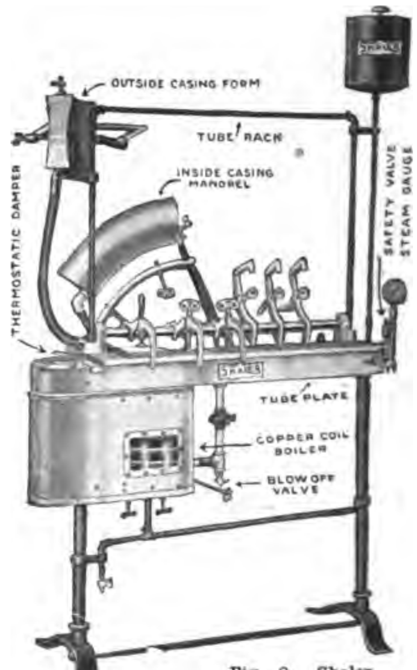


Fig. 2. Shaler steam vulcanizer.

Example of an Anti-Skid Tread Repair.

Should a tire have a non-skid pattern on the tread and a section is to be replaced, the wrapped tread method as explained in the Shaler instruction book is as follows:

Take a piece of canvas (Para coated one side) large enough to cover the repair. Apply to coated side, three layers of ordinary tread stock. Find a good place on tire, dust it with soapstone, and apply this "pad" fig. 9, with the raw rubber side next to tread. Place tire on vulcanizer, wrap tape over pad and tire, tighten tape, put on outside heater (fig. 2) and cure for half an hour. The pad will then have taken an impression of the tread and will be like fig. 9. This may be done while you are waiting for the cement to dry on the repair.

Fig 9.

When the repair is ready to vulcanize place pad over repair, wrap binding tape over it. When heated, the original tread pattern will be duplicated. Save pad for future use and mark it.

If it is unnecesary to replace a portion of the tread, but wish to protect the tread from being flattened by pressure of tape when curing, simply make a thick paste of soapstone and water and then fill depressions in tread with it before wrapping with the tape. When repair is cured the dried soapstone is brushed off and saved for future use.

CHART NO. 241—Vulcanizers For Repair Shops. See also page 610 for a Tire Repair Outfit and Tools. **Prices to Charge For Tire Repair Work. Example of an Anti-Skid Tread Repair.**

*Also used for drying out tires when repairing. **Tires should be free from all moisture when vulcanizing,** as moisture turns to steam when heat is applied and forces fabric layers apart, making a weak repair.

Repairing a Blow-Out by the Wrapped Tread Method of Vulcanizing.

The "sectional" method, where repair was built up or reinforced from the outside, was explained on page 573. With the wrapped tread method, it is built up or reinforced from the inside.

While we speak of blow-out repairs, this also covers repairs for cuts through tread and carcass, also side-wall and rim repairs.

When Step Cutting Is Necessary.

If the fabric immediately around hole is rotten and shredded so badly that it is impracticable to work it back into the repair, then it will be necessary to remove any loose canvas that may be around the blow-out, "step cutting" it out in two or three steps, similar to fig. 8, page 573, but from the inside. This method however, will not be required once in twenty repairs.

Cut the steps so that the smallest is at least 2" larger in every direction than the hole through the tire, and make each succeeding step about 1½" larger all around the one below it.

Coat all over with cement, working the cement in between plies of fabric at the ragged edges of the damaged part. After first coat has dried for an hour or two put on another coat and let it stand for several hours—over night if convenient.

Cut layers of blow-out canvas (Para coated on both sides) to fit the steps from which fabric was removed and work them thoroughly in place, one at a time. Roll from the center to the edges of the patch, and if air bubbles form under the canvas prick them with an awl and roll them flat. It is necessary that the canvas be laid smoothly and that perfect contact be secured between the different layers.

Then put on another patch an inch larger all around than the largest step. Finish with plain friction canvas or canvas Para-coated on one side. This last layer must be long enough to entirely cover the preceding patches and **reach to the clincher on the outside.** Use from four to six layers of canvas, depending upon the size of the tire and size of the hole through it.

Reinforcing Without Step Cutting.

The following method is where fabric is not rotten and procedure is as follows:

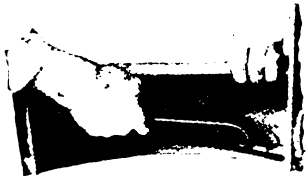

Fig. 20: Clean inside of tire about 6" on each side of hole. Use gasoline to soften. Scrape until bare canvas is exposed, but do not cut fabric.

Fig. 21: Apply 2 coats of cement over cleaned surface. Let first coat dry ½ hour before applying the second. Cement hole through tire thoroughly.

Fig. 22: Cut first layer of fabric (Para-coated both sides) so will extend 1" beyond hole in every direction. Roll smoothly in place, pricking any air bubbles to let air escape.

Then cut a second layer of fabric (Para-coated both sides) large enough to cover the first one and let it extend an inch over it in every direction.

Then cut a third layer (Para coated both sides) 1" larger, and place over second layer in same manner and roll it down.

Then cut a fourth layer (Para coated one side) 1" larger than third layer and apply the Para coated side next to the third layer. In large tires use 5 layers. After the 3rd and 4th layers are applied the patch will look as shown in fig. 23.

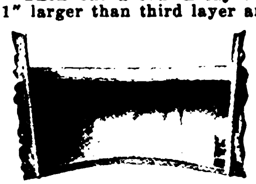

Fig. 23.

Fig. 23 shows appearance of patch after all layers have been applied and rolled down.

Fig. 24.

Fig. 24: Turn tire over and fill gash with tread stock of narrow strips and press down carefully. No cement is necessary. Do not fill hole too full. Sprinkle inside with soapstone.

Fig. 25.

Fig. 25: Place tire over the "inside casing mandrel" (see fig. 2, page 574). Lay a piece of waxed paper over outside repair and place bead strips along the bead as shown, then wrap on tape and tighten tension of hand screws so as to pull tire down on mold.

Fig. 26. Apply heat to inside and outside simultaneously.

Fig. 26: Place "outside casing form" or mold over outside repair, apply the steam. Cure for fifteen minutes, then loosen clamp, tighten tape. About 50 minutes in all is required. Larger tires 1 hour at 40 lbs. of steam pressure.

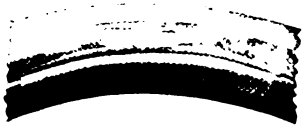

Fig. 27.

Fig. 27 Shows a blowout repair near rim. Same method was used, except the last layer of fabric is brought clear around the bead and up outside of tire far enough for the bead strip to get a good grip, then use the curved side of the "outside form" or mold for rim work.

CHART NO. 241-A—Wrapped Tread Method of Repairing a Blow-Out—where repair is built-up c reinforced from the inside. The Shaler Steam Vulcanizer, fig. 2, page 574 is used as an exampl

To repair a section of tire where tread is loose—see footnote, page 570.

INSTRUCTION No. 43.

†DIGEST OF TROUBLES: How to Diagnose or Locate Engine Troubles; the Cause and Remedy. Miscellaneous Questions Answered. *USEFUL AND INSTRUCTIVE HINTS AND SUGGESTIONS.

Making a Diagnosis.

Diagnosing automobile troubles requires thought and reasoning. If a person understands the principle and construction of the various parts of a car and some one of the hundreds of troubles occur, then simply reason it out; ask yourself what the trouble is, what could cause that trouble and why. Find if it is ignition, carburetion, cooling, or just what the trouble is, and then figure it out the best you can before proceeding.

It is of little use to turn the engine over and over by the starting handle or by means of the engine starter, in an effort to set it going. If the engine will not start with a few turns, the chances are that there is something radically out of order, requiring intelligent attention. With the carburetor giving a correct mixture, the ignition system affording a hot and effective spark, and everything else apparently all right, it should be as easy to secure an explosion on the second stroke as on the sixtieth. So if the engine will not start with the second or third attempt it is not likely to start with three or four hundred attempts; consequently it is better to find out the cause of the trouble than to turn the engine over indefinitely and run the battery down.

Before an Engine will Run there are Two Essentials.

Always remember when diagnosing troubles that there are two essentials necessary before an engine will run. First, gasoline; second, a spark.

The gasoline must reach the inside of the cylinders and the spark must be there at the proper time to ignite the gas. If you have both, something is bound to happen, even though it is but a single explosion.

Next, remember that even though you have a spark and gasoline—the engine will not run **properly** if the gas does not enter the cylinder at the right time "and stay there" and be in a proper gaseous form.

The gas cannot be ignited regularly if there is not a good, hot spark at the correct time.

Next, remember that if an engine is not properly lubricated and cooled it will **heat,** and if too cold, heat must be applied for proper carburetion. (See page 155.)

Therefore, in summing up the chief troubles, we find that most troubles are due to ignition, carburetion and lubrication.

If trouble occurs, first find which of the three headings the trouble comes under and then reason it out.

The object of this digest or condensed form of troubles and remedies is to simply give you an idea what would likely cause certain troubles and what would likely remedy them. The reader will then decide which one is most likely the trouble and if he does not know the meaning of certain adjustments called for, then turn to the index, find the subject mentioned and read up on that subject.

†Systematic Trouble Hunting by a Process of Elimination.

In dealing with engine troubles one should always try to figure out the possible cause of a trouble before starting to adjust something that does not need adjusting.

An adjustment never should be changed without a knowledge of why the change is made, the effect the change should have and how to restore the mechanism to its original adjustment.

If one will first reason out the probable causes of a trouble: the real cause can be quickly located. For instance, if a **single lamp fails to burn**—you will **know** the trouble is not in the battery or generator if **all** the other lamps burn—therefore the cause must be in that lamp, socket or wiring.

Similarly, if **the starting motor fails to start** engine, yet you know it is turning the engine crankshaft, and your lights burn brightly—you would not look to the battery for the trouble, but you would **know** that the trouble must be with the ignition or carburetion. It is then a matter of applying the **process of elimination**—that is, test **each** of the remaining probable causes until the final cause is the only one left.

When the possible cause of trouble can not be imagined, then begin with a careful examination of all the features of the engine that are apt to give rise to the trouble.

If nothing out of order is found, then begin testing out the various features, beginning with the easiest and most accessible, and thoroughly complete each test before starting on another possible cause.

For example: If your ignition system is suspected, the easiest thing to test would be the spark plugs, first find the faulty plug, then proceed from the spark plugs to the wiring communicating between the plug and the distributor, then examine the battery connections, the switch connections and, last of all, the adjustments of either the timer, coil or magneto.

Do not examine a spark plug and then leave it and try a few carburetor adjustments and later come back for another spell of tinkering with the ignition, etc.

If you suspect the ignition system, go to it from beginning to end in a SYSTEMATIC manner before proceeding with the carburetor and likewise with other parts.

†See page 419 for "**Digest of Lighting Troubles,**" and pages 457, 458, 422 **Storage Battery Troubles** and page 566 **Tire Troubles**—See index for other troubles.

*See Instructions 45 and 46D for Useful Devices for the Repair Shop and Repair Shop Hints.

*DIGEST OF GENERATOR TROUBLES.

When Troubles occur in the electric system of a car, remember that the electric system is divided into four parts, namely: the **lighting** circuit, **generating** circuit, **starting** motor circuit and **ignition** circuit. The idea is then to determine which of the circuits the trouble is in and then test it from beginning to end, as explained on pages 429 and 737, 576. See also, pages 407, 411, 408, 416, 424, 419 for other electric troubles. **The troubles, indications and causes of generator troubles can be classed under two heads;** those which are due to **mechanical** defects and those due to **electrical** defects.

Mechanical Generator Troubles.

Indications: Noise and low current generated or no current at all.

Causes: (1) Broken bearing (examine by turning armature by hand, if it sticks or turns hard, look to ball bearings and replace); (2) Loose driving gear or pinion (if loose, key to shaft); (3) Armature off center (can be due to loose pole pieces. See that the screws with countersunk heads on outside of generator are tight); (4) Shaft bent (this is more common on starting motors than on generators. A new armature is required if shaft is bent); (5) Commutator burst (when this happens the brushes and brush holders, etc., are also damaged. A new armature, brushes and brush holders are required).

Electrical Generator Troubles.

Electrical troubles can be classified under: (a) open circuits; (b) ground or short circuits; (c) defective regulation system; (d) defective cut-out.

(a) **Open circuit indications** would be low current generated or none at all.

Causes: (1) Brush connections poor; (2) Brushes stuck; (3) Brushes worn too short; (4) Brush spring broken, no spring pressure to hold brush to commutator; (5) Dirty commutator (see pages 404, 409); (6) Armature if open by connection loose at commutator or broken coil would cause intense blue sparking at commutator and flattened commutator bars; (7) Field coils if open will show no current at all, or if partial open, low current generated.

(b) **Ground or short circuits** (1) may be at main terminals; (2) Brush connections; (3) Brush holders; (4) Armature if short circuited will cause excessive heating of armature, insulation burned and low current generated; (5) Field coils if short circuited will cause field coils to heat and low current generated; (6) Commutator if short circuited will cause no current at all or low current output.

(c) **Regulation:** In this instance we will deal with the "third-brush" system of regulation. If a "voltage regulated" system is used see pages 343, 345 and 925.

Indications will be that the charging current will be too low or too high and not remaining constant at high speeds.

Causes: (1) Incorrect setting of third-brush (see pages 405, 389, 925, 864C); (2) Brush not sanded in (see pages 404, 409); (3) Spring pressure on brush not sufficient (see pages 404, 408, 864C).

(d) **Cut-out, if it remains open at all times,** result will be; (1) No current to battery; (2) Generator will get very hot; (3) Will burn generator out.

(d) **Cut-out, if it remains closed at all times,** result will be; (1) Battery will discharge back through generator at about 20 amperes (on the Ford) when engine is not running or not running fast enough. This will discharge battery.

**DIGEST OF STARTING MOTOR TROUBLES.

Starting motor troubles, indications and causes may also be classified under two heads; those which are due to **mechanical** defects and those due to **electrical** defects. (See also, pages 407, 408).

Mechanical Starting Motor Troubles.

Indications: Excessive current draw and slow cranking or complete failure to crank and excessive noise.

Causes: (1) Worn brushes; (2) Shaft bent; (3) Commutator burst; (4) Loose pole-pieces; (5) Broken Bendix (see page 331); (6) Armature off center (may be due to loose pole pieces, tighten screws).

Electrical Starting Motor Troubles.

Electrical troubles are classified under (a) open circuits; (b) ground or short circuits.

Open circuit indications would be indicated by low current or no current and failure of starting motor to operate. If only partial open circuit occurs the current draw will be low and cranking slow.

Open circuit causes: (1) Brush pigtails loose; poor brush spring pressure; dirty or burned commutator; (2) Armature commutator blue sparking or flattened commutator with slow cranking; (3) Fields open; (4) Starting switch open; (5) Loose connections at battery, ground or switch.

Ground or short circuit indications are excessive current required, no cranking or slow cranking.

Grounds or short circuit causes: (1) Shorted fields cause excessive current and slow cranking; (2) Armature shorted causes excessive current, burnt insulation, slow cranking; (3) Commutator shorted causes excessive current, no cranking; (4) Brush rigging shorted causes may be in main terminal, brush holders, pigtails loose.

STORAGE BATTERY TROUBLES.

This subject is treated under the Storage Battery Subject. The "care of a battery" is given on pages 454, 455.

Miscellaneous battery troubles are treated on pages 456, 457, 458, 459, 421, 422 and 416.

*See also, pages 409, 411, 416, 429, 737, 864C for **Generator Troubles.**
See also, pages 407, 408, 416, 429, 737, 864A, 424 for **Starting Motor Troubles.
See page 581 for list of pages where **Other Troubles** can be found.

†A DIGEST OF ENGINE TROUBLES; Cause and Remedy.

Ordinary engine troubles are generally of three kinds: (1) Engine will not start; (2) starts but misses; (3) starts and runs regularly but no power.

The following matter refers principally to ignition and carburetion troubles.

‡ENGINE FAILS TO START.

(1) LACK OF GASOLINE: **See that there is gasoline in the tank and that the shut-off cock is open. Make sure that gasoline is flowing to the carburetor by priming or pushing down the carburetor float. If the carburetor is too full the gasoline will drip. If the carburetor is not full enough, look for a stoppage in the gasoline pipe and see that the vent hole in the tank cap is open, see (73). See also, page 407.**

(1A) CARBURETOR NEEDS PRIMING: **Either prime carburetor or close air intake valve. (see pages 153 156 and foot notes, page 489).**

(2) *POOR QUALITY OF GASOLINE: **Some of the gasoline offered for sale is of such poor quality that it will not vaporize when the engine is cold. The gasoline may contain water, which will freeze in cold weather and clog the gasoline pipe. Old or stale gasoline may also cause difficult starting.**

(3) TOO MUCH GASOLINE: **The cylinder may be flooded with gasoline; spark plug soaked. Open the relief cocks, cut off throttle and crank engine until excess is eliminated and an explosion occurs. Then close relief cocks, open throttle only partial way and try cranking again; engine ought to start. Float may be loose. (see page 167 and foot note page 489.)**

(4) NO PRESSURE IN FUEL TANK: **If the system is a pressure fuel system, then use the hand pump and try priming carburetor. (see page 164, fig. 2.)**

(5) LACK OF IGNITION CURRENT: **If battery ignition, see if battery is strong. Remove one of the spark plug wires and hold it about ⅜ of an inch away from plug and terminal and see if the spark jumps the gap when the engine is cranked.**

(6) IF STARTING MOTOR FAILS: **See page 577 and pages 404, 416, 429, 737.**

(7) SPARK PLUGS: **Spark plugs may have become sooted from over-lubrication or if they have seen considerable usage the points may be burned and corroded. If water has been splashed on the engine when it was hot, the porcelain of the plugs may be cracked. See that the sparking points are perfectly clean and that the gap does not exceed .025 of an inch for coil ignition or .020 to .031 of an inch for magneto ignition, (see charts 112 and 113.) Also see pages 301, 233.)**

ENGINE STARTS BUT MISSES.

(8) CARBURETION ADJUSTMENTS: **If on a cold day and engine has just been started, wait a few minutes for engine to warm up—closing air intake.**

If missing still occurs with popping back or "sneezing," this indicates the mixture is too lean; give the needle valve of carburetor a slight opening until engine runs smooth. If no needle valve is provided, give less air in the auxiliary air valve, see pages 170, 153, 168 and foot note page 489.

(9) IGNITION: **If missing continues after engine is warmed up, and more gasoline is fed as per (3), examine the spark plugs and test as per (3). (See also, pages 236, 237.) Weak battery: if coil and battery ignition. (See pages 249 and 450 and Instruction 29.)**

ENGINE STARTS BUT "POPS" AND "SNEEZES" IN CARBURETOR.

(10) CARBURETION: **See (8), also page 170.**

ENGINE STARTS BUT WILL NOT PULL.

(11) CARBURETION: **See (8) or there may be an over rich mixture. This would be indicated by black smoke.**

(12) THE VALVES: **May be leaking and there might be poor compression.**

(13) IGNITION: **The spark may be weak, this, however, would be indicated by missing. Test battery—see pages 450 and 249, 250, 253.**

ENGINE RUNS REGULARLY FOR A FEW MINUTES AND THEN STOPS.

(14) CARBURETION: **In cold weather this is more liable to occur, until engine is warm; give slightly more gasoline by closing air valve (if one is provided); gasoline may not be flowing freely to carburetor. Prime carburetor and see if it drips. There may not be enough gasoline; closing air valve will determine. Maybe too much gasoline (see 3).**

(15) IGNITION: **Battery may be weak. Ignition may be retarded too much. If there are two systems of ignition try the other one.**

ENGINE STOPS SUDDENLY.

(16) CARBURETION: **Lack of gasoline. Stoppage of gasoline pipe (prime carburetor and if no gasoline, examine tank, then fuel strainer). see (73).**

(17) IGNITION: **Loose wire. Short circuit, loose switch connection. If magneto ignition, switch to coil and battery. Weak battery. Points of interrupter may be closed by pitting, see pages 298, 300 and 249.**

(18) **A sudden stoppage is almost always due to ignition trouble, for gasoline trouble will stop engine slowly.**

ENGINE STOPS SLOWLY WITH MIS-FIRING.

(19) CARBURETION: **See (16). The needle valve sometimes jars itself closed.**

(20) **When an engine stops slowly, the explosions becoming weaker and weaker until they cease, it is likely due to gasoline trouble. The fault will be found in the failure of the mixture to reach the cylinder. (see 73.)**

(21) IGNITION: **Batteries exhausted, plugs fouled through over lubrication.**

ENGINE LOPES OR LOADS UP.

(22) CARBURETION: **When engine slows down irregularly, speeding up and then slowing down again as though fitted with a governor and if throttle be closed further, in order to slow down more, engine stops. Air has leaked in between carburetor and cylinders. Examine gaskets around the joints of inlet pipe or where carburetor is attached to intake manifold. Too much gasoline will also cause "loping." Cut down on the carburetor gasoline feed.**

(23) IGNITION: **The spark may be set too far advanced. If this is the case, loping is likely to occur when spark is fully retarded. Therefore test the time of ignition, (see page 317 "Testing ignition advance.")**

LACK OF FLEXIBILITY.

(24) CARBURETION: **This trouble is almost exclusively a carburetor fault and is due to the fact that the auxiliary air intake being so constructed that it furnishes an abundance of air on high speed, is not sensitive enough on low, when the throttle is nearly closed the engine stalls; or when the throttle is suddenly opened there is no "get away" because the auxiliary air inlet valve allows an inrush of air, forming a mixture good enough for high speed running but too weak for "pick up" purposes. This calls for careful adjustment of the auxiliary air valve and gasoline needle valve. (see pg. 150 to 164.)**

*Very common in cool weather—see pages 153, 161, 155, 170 and foot note bottom of page 489.

†See page 419 for "Digest of Lighting Troubles," pages 457, 422, 416, 458 for "Storage Battery Troubles." ‡See also, pages 798, 799, 800, Ford Engine Troubles.

***ENGINE MISSES EXPLOSION.**

(25) DEFECTIVE OR DIRTY SPARK PLUG: With the engine running idle, short circuit the spark plugs one at a time by touching a screwdriver from the metal of the cylinders to the terminals of the plugs. (see pages 237, 249.) This prevents the plug from firing and when one is short circuited—that makes no difference in the running of the engine—you have probably located the plug at fault. If the spark plug wire is properly connected to the distributor, either clean or install a new plug in place of the one that has been found defective. If a vibrator coil, see page 236. (also see 17).

(26) **SPARK PLUG GAP TOO WIDE:. The distance betwen the spark plug points should not exceed .025 of an inch. (see 7.) Examine interrupter points. (see pages 250, 378 and 301). Weak battery.

(28) TOO LEAN A GASOLINE MIXTURE: If the engine misses with a popping noise in the carburetor, the indications are that too much cold air is being admitted through the air regulating valve, the carburetor jets have become clogged with dirt, or there is a partial stoppage somewhere in the gasoline pipe connections. See that carburetor intake header gaskets are perfectly tight and do not admit air, which would thin the mixture. (see pages 162, 168 and Instruction 13.)

(29) LOOK FOR GASOLINE TROUBLE: Dirt in gasoline tank over outlet, dirt or water in carburetor, float leaking, jet in carburetor clogged up, supply cock loose, inlet valve sticking or leak in inlet pipe, weak exhaust valve spring, may be a leak of air in inlet pipe.

(30) If the engine misses, and the following explosion is accompanied by an explosion in the muffler; ignition is at fault, for the charge has reached the cylinder correctly, but has been exhausted without being exploded.

****ENGINE MISSES ON HIGH SPEED.**

(31) IGNITION: Weak battery (if coil and battery ignition, see page 450). If the engine misses at high but not on low or on a hard pull, then it is evident the spark plugs are O.K.

The contact screw in the contact breaker box needs screwing up (page 297 250, 378.) A word of explanation on this; the engine may fire all right at lesser speeds, because the speed is slow enough and the contact is long enough to allow the coil to build up, but at high speeds the contact is too short, consequently a slight turn of the contact screw is needed.

Try switching to the other ignition system, if a dual system is provided, this will determine which ignition system is at fault.

The coil may be defective. see index and pages 235, 236, 249 and 253 for "Testing a coil."

(32) CARBURETION: The carburetor may have been adjusted for slow speed, but requires more gasoline on high speed, or it may be getting too much gasoline. Proper adjustment of carburetor ought to suffice.

****ENGINE MISSES ON LOW SPEED.**

(33) IGNITION: If magneto ignition, the cause may be due to the slow speed of magneto and weak current generated. Try advancing the spark more. Also examine the interrupter points.

Examine spark plug points (see 7). If not remedied, try switching to the other system of ignition. If missing still occurs, then there are two other points to consider; loose connection or a broken down coil, if one coil is used for both systems, as a low tension magneto—see page 241.

(34) A SPARK PLUG MAY BE FOULED: It has been known that a bad plug will not cause missing at all speeds (page 235).

(35) CARBURETION: Mixture at fault—readjust slow speed adjustment. The float may be too low giving over rich mixture. See also, page 171.

(36) THERE MAY BE A LEAK IN THE INTAKE PIPE: This is a very common cause for missing at low speeds, and is best detected by allowing the engine to run at the missing speed. Take a squirt can full of gasoline and squirt around all the intake pipe joints. If you detect any difference whatsoever in the running, there is a leak. The remedy is obvious, see pages 162 and 171.

ENGINE MISSES AT ALL SPEEDS.

(37) IGNITION: Defective spark plug (see 7 and 25.) Loose connection. Weak battery. Loose switch parts. Broken wire. Slight short circuit (see page 241, and charts 112 and 113.)

(38) CARBURETION: see pages 166 to 171.

†ENGINE DOES NOT DELIVER FULL POWER.

(39) VALVES: Leaky exhaust valves, scored cylinder, worn or loose rings cause loss of compression, see page 626. Timing of valve may be wrong. Exhaust and inlet may not open at correct time. See page 110 for "checking valve timing," and page 92 and page 630 on "valve grinding" and pages 94 and 95 "valve clearance" Weak inlet or exhaust springs. Examine cams for wear.

(40) CARBURETION: Too rich a mixture (see pages 166 to 171).

(41) OVERHEATING OF ENGINE: Lack of oil. Circulation system defective (see page 191.)

(42) IGNITION: Timing of ignition may be wrong. Set too far retarded or too far advanced. (see page 249). Weak ignition. Defect in distributor.

(43) MISCELLANEOUS CAUSES: Dragging brakes, leaky piston rings, lack of lubrication. Tight bearings. Flat tires. If new piston rings fitted they are not fully set, use plenty of oil. See also, page 609.

††ENGINE OVERHEATS.

(44) VALVES: The exhaust valve may not open early enough to pass out the burnt gas.

(45) CARBURETION: Too rich a mixture (see pages 166 to 171) or driving with throttle open too far and spark retarded too much.

(46) IGNITION: Running on retarded spark invariably causes heating (see page 67 and 68.) Test the ignition timing, see index.

The spark lever should be raised up or advanced as far as possible at all times without causing the engine to knock, also see page 319, for "Spark control and overheating."

(47) LACK OF LUBRICATION: Examine the oiling system, see bottom of page 201.

(48) COOLING: Constricted water circulation (see pages 191, 193, 788); examine the water circulation and pump. Under sized radiator.

(49) CARBON DEPOSIT: See page 201 and 202. Choked exhaust.

(50) SLIPPING FAN BELT: Tighten the belt.

*See pages 236, 298 and index. ††When engine overheats by steaming, due to frozen water—feel of radiator at bottom—if cold it is frozen, if warm then circulation is o.k. and trouble is due to lack of water or something else—see also pages 193, 788, 800.

†See page 586, "Spark Plugs Indicate Condition of Valves, and page 626, "Engine, Why Loses Power."

**See pages 171, 235, 297, 298 and index.

(51) Brakes dragging:. Examine the brakes with rear wheels jacked up.

(52) BEARINGS: If engine is new or just overhauled, the bearings may be too tight. Put in plenty of oil and run until loosened up, see page 203.

(53) DRIVING TOO LONG ON LOW GEAR: This is bad practice and should be avoided.

Note.—Refer to page 188 and note the "motometer." This is an excellent device to assist in diagnosing overheating troubles. Overheating is always manifest when engine begins to run slow and pounds.

ENGINE KNOCKS.

(54) IGNITION: The most common knock is the ignition knock, caused by too much advance of spark. Back lash, in timing wheel teeth, see pages 638, 790 and index for "knocks."

(55) BEARINGS: The connecting rod or main bearings may be loose. (see index for "testing", also "tightening bearings.")

(56) CARBON DEPOSIT: This is also a frequent cause, see page 201 to 203; also see page 623 for carbon troubles.

(57) LOOSE OR WORN PISTONS: Will cause a knock as explained in chart 254.

(58) CARBURETION: Too rich a mixture will cause a gas knock.

(59) ENGINE OVERLOAD ON HILL: Shift to lower speed.

ENGINE WILL NOT STOP WHEN SWITCHED OFF.

(60) IGNITION: If firing is regular the switch is defective. If firing is irregular, pre-ignition is the cause. Caused by poor oil as explained on page 202. This carbon hardens and becomes red hot, hence "pre-ignition," (see index "pre-ignition.")

Stop engine by closing throttle and as soon as the engine cools, locate the cause.

(61) MISCELLANEOUS OTHER CAUSES: Overheating as explained from (44) to (53), this instruction, may be the cause.

ENGINE RUNS WELL BUT CAR DRAGS.

(62) CLUTCH IS LIKELY SLIPPING: The spring needs tightening. If leather faced cone type; too much oil on the leather. Clean with gasoline squirted on with an oil gun. If this don't hold, use Fullers earth (last resort). If multiple disc type; clutch spring at fault or plates worn.

A slipping clutch is detected by the engine speed not conforming with speed of car when throttle is opened. This ratio between car and engine is soon learned by experience.

CLUTCH DRAGS.

(63) IF CONE TYPE: The clutch may not clear the fly wheel when thrown out. If multiple disc type; the oil may be too heavy and sticks to plates, (see instruction 15, page 203).

CLUTCH GRABS OR IS FIERCE.

*(64) IF CONE TYPE: Leather too dry, clean with gasoline (see 62) then put on castor oil or neats foot oil to soften.

If multiple disc use lighter oil after cleaning. Spring may be too tight, (see repair subject "care of clutch.")

OIL ON CLUTCH LEATHER—(cone type)—see page 38 and index, "clutch repairing."

(67) CAUSE: Too much oil in crank case—oil works out engine bearing.

ENGINE BACK FIRES IN MUFFLER.

(68) IGNITION: Usually occurs when coasting with spark off and retarded and suddenly throwing on switch, thereby firing charges which have entered muffler unfired.

(69) CARBURETION: Mixture too weak to fire, or mixture right but sparking wrong, one cylinder missing fire and pumping explosive charges into muffler which ignites from heat of the next exhaust change. Missing of ignition, valves leaking. Gasoline supply failing. (see page 168 to 170.) Remedy: (1) Examine as in last section; particularly see if the plug points are too far apart. (2) See that all cylinders are firing regularly. (3) Adjust carburetor. (4) See if plenty of gasoline in tank.

CRANK CASE BECOMES VERY HOT AND ENGINE WEAK.

(70) CAUSE: Serious leak of exploded gas past piston rings—rings worn or broken—crack in head of piston—piston pin loose in piston and allowing gas to escape along bearing. See repair subject for "testing piston ring leaks."

OVERHEATING OF EXHAUST PIPE AND MUFFLER.

(71) CAUSE: Carburetor trouble over-rich mixture, valves out of time, very late spark, running too long on low gear, using too much gas, exhaust throttled, insufficient lift on valve or choked muffler.

This condition is the result of something by which the mixture is not completely burned in the combustion space, but continues to burn in the exhaust pipe and muffler.

A mixture that is too rich or too poor, usually the former, will burn slowly and will still be burning during the exhaust stroke.

If the exhaust valve opens too soon, the charge will escape before it has done its work.

Very late ignition will not give enough time to permit the charge to be burned before the exhaust valve opens.

ENGINE MAKES AN UNUSUAL HISSING NOISE.

(72) CAUSE: Spark plug porcelain broken, joint between engine and exhaust pipe loose, exhaust pipe cracked, compression cock worked loose, spark plug not tightly screwed into cylinder, valve caps may be loose; probabilities are the exhaust pipe or a spark plug is loose.

GASOLINE FAILS TO REACH THE CARBURETOR.

(73) CAUSE: Gauze strainer in base of carburetor choked—obstruction in the supply pipe—air lock at a bend in supply pipe—(see page 192, refers to water) pressure leakage from tank, or if a gravty tank it may be air-bound—floating obstruction in gasoline tank covering the gasoline outlet—gasoline pipe near exhaust pipe causing a vapor lock. Vent hole in filler cap clogged.

CONTINUAL EMISSION OF SMOKE FROM MUFFLER.

(74) CAUSE: Engine being over-lubricated; readjust lubrication to give a slower rate of oil flow—the emission of black smoke indicates that the carburetion is too rich. (see pages 202, 169). Piston rings leak.

CRACK IN CYLINDER.

(75) EFFECT: . Water in combustion chamber or in crank chamber—air bubbling through radiator on pulling engine over compression. (see page 713.)

CARBURETOR DRIPS.

(76) CAUSE: Float valve mechanism out of order; examine float and grind the float needle valve. Usual cause is due to dirt under needle valve or float set too high. (see also, page 167.)

ABNORMAL NOISE FROM TRANSMISSION GEAR.

(77) CAUSE: (Other than due to unskillful changing of the gears)—want of lubrica-

*Numbers 65 and 66 omitted; error in numbering.

tion of gears in change-gear box or bevel drive on back axle—pinions damaged—teeth broken or worn down—nut loose in gear box and fouling gears—clutch drum or fly wheel loose—universal joints on transmission shaft badly worn or damaged—bearings in gear box worn, allowing shafts to rock about—sliding member of clutch out of alignment with cone (sets up harsh grating noise)—wear of jaws of positive clutch in gear box.

SQUEAKS AND SIMILAR NOISES.

(78) CAUSE: Fork actuating clutch wants lubrication—one or more bearings overheating and want of lubrication—one or more of the brakes partly on—bearings of spring shackles want lubricating(on some cars the spring ends work in a slide, which requires occasionally lubricating)—valve stems running dry in the guides. Fenders and hoods are usually the cause of most noises.

LUBRICATOR STOPS WORKING.

(79) CAUSE: Oil pipe choked—feed nipples choked—pump shaft may be broke, usually due to clogged pipes. May need priming. Loose connections.

OIL FEED GAUGE DOES NOT SHOW FLOW OF OIL.

(80) SEE IF OIL IN CRANK CASE. Clean Strainer. Examine pump and pipe connections. Oil may be too cold to flow. (see page 199). Oil pump may need priming.

OIL LEAKAGE FROM ENGINE.

(81) CAUSE: Bearings badly worn and passing out bearing journal—gaskets not tight—screws loose. Crank case flooded with oil (lubricator working too rapidly). Cap screws holding lower crank case not tight. Gaskets leaking.

For ignition troubles see pages 233 to 241, 247, 249, 253, 543.

For magneto troubles see pages 297 to 300.

For carburetor troubles see pages 166 to 171.

For starting motor troubles see pages 416, 422, 408, 429, 737, 577, 864A.

For cooling troubles see pages 189, 191, 789, 714, 715.

For generator troubles see pages 409, 411, 416, 429, 737, 864C, 410.

For carbon troubles see pages 202, 624, 625 and index.

For storage battery troubles see pages 454, 457, 458, 421, 422.

For miscellaneous repairs and adjustments see Instruction No. 46.

For Tire troubles see pages 566, 567.

QUESTIONS ANSWERED.

The following are some of the questions answered by A. L. Dyke in the St. Louis Globe-Democrat and the New York Times—Automobile Query Columns, during the past few years. The questions and answers have been partially classified.

First Auto Show.

Q.—What year was the first automobile show held in Chicago and also New York?

A.—The first show held in New York was in November, 1900, at Madison Square Garden, under the auspices of the Automobile Club of America. A feature of the show was a board hill built on the roof of the garden, to prove that the new vehicle would not only propel itself, but would climb a grade. The novelty of the idea appealed to the public. The first automobile show in Chicago was at the Coliseum in March, 1901. Eighteen vehicles were displayed. The gate receipts were $3,200. Mr. Sam Miles was the manager.

First Four-Cycle Gasoline Engine.

Q.—Who invented the first gasoline engine?

A.—Nicolaus August Otto, Deutz, Germany, on August 14, 1877, was granted patents covering the four-cycle engine and the principle of compressing the mixture before exploding it. This is the principle still used on automobile engines at present. The conception of compression and four cycles of operation was not, however, original with Otto. He combined these ideas into a practical engine. They were twelve years in the making, and three countries participated in their evolution. The conception started in 1862, when a Frenchman, Alphonse Beau de Rochas, obtained a patent and wrote a pamphlet on the four-cycle engine. Six years later Boulton, an Englishman, secured a patent covering the use of compression in an engine. However, Boulton failed to work out the necessary means for compression in a practical way.

First Power Propelled Vehicle.

Q.—When was the first power-propelled vehicle invented?

A.—Experiments date back to 1770, when Joseph Cugnot, a French engineer, built the first automobile. He constructed a steam automobile that hauled 2½ tons three miles per hour, and this vehicle is still preserved in France. In 1802, the first practical steam automobile was built by Richard Trevitluck of England, using a crank shaft for the first time and driving by gears from the engine to the road wheels. In 1821, Julius Griffiths of England built the first comfortable steam vehicle, the first vehicle to have a coach design of body, with seats carried on springs, as they are today. In 1831 Summers & Ogle of England built a three-wheel tubular boiler and two-cylinder engine which attained a speed of thirty-two miles per hour. The first motor vehicle to carry passengers regularly for hire was built by Walter Hancock of England in 1834. The motive power was steam.

First Pneumatic Tires.

Q.—(1) Who invented the pneumatic tire? (2) What year did American manufacturers of automobiles begin to use the double tube tire? (3) What were the prices of tires from 1900 to 1915?

A.—(1) At present the honor of inventing pneumatic tires is disputed between two claimants: R. W. Thompson, a Scotchman, and John Dunlap, an Irishman. The former devised an automobile rubber tire in 1839, but it never came into use, as it was a very crude affair and seemed of no practical service. Thompson's tire was a single tube appliance and was invented in 1845. The solid rubber cushion tire and the single-tube air tire was used considerably in 1899 and 1900. The double-tube penumatic tire did not come into general use on automobiles until 1902. (2) Single-tube pneumatic tires were generally used up to 1903. Double-tube tires were in use in 1902 and were extensively adopted in 1903. (3) For a 30x3½-inch single-tube tire the price in 1900 was $28; in 1901, $25; in 1903 the double-tube tire casing and tube cost $41; 1913, $21.95; 1915, $14.30.

First American Auto Road Race.

Q.—Where and when was the first American Automobile Road Race run in America?

A.—Motor Age, April 19, 1900, says: "America's first auto road race was run over a fifty-mile course on the famous Merrick road on Long Island yesterday morning. A. L. Riker, with a five horse-power electric racing wagon, won by a quarter of an hour; time, 2:03:30. S. T. Davis, Jr. in a steam Locomobile, four and a half horse-power, was second; time, 2:18:27. Alexander Fisher, in a gasoline runabout built by the Automobile Company of America was third; time, 2:30:01." The article further states that the racers wore auto caps, goggles and mouth protectors. Riker wore no auto togs at all, but got there just the same. This speed is averaged now almost daily on the streets.

First Auto Race.

Q.—Where was the first automobile race held in America? How many cars started? How many finished?

A.—Chicago made the earliest attempt at an automobile race, November 25, 1895. Six cars started over a course of fifty-four miles, from

Jackson Park to Evanston and back again, for a prize of $500 offered by the Chicago Times-Herald. Four of the cars were propelled by gasoline and two by electricity. Two cars finished. Charles E. Duryea won in ten hours and twenty-three minutes. The course was covered under highly unfavorable conditions, the roads being heavy with mud and snowy slush.

†Speed, Motorcycle vs. Auto.

Q.—What is the best time ever made by a motor cycle? Some say the motor cycle is faster than any automobile.

A.—The best time ever made by a motor cycle was one mile in 37 seconds, or less than 100 miles per hour.* This was accomplished by Lee Humiston at the Los Angeles Motordrome, November 5, 1911. The fastest automobile time ever made was by a Fiat, driven by Arthur Duray at Ostend in 1913; time 142.9 miles per hour.

Earnings of Racing Drivers.

Q.—What are the earnings of racing drivers?

A.—During 1915 Resta earned $37,750; Anderson, $37,000; Cooper, $31,750; De Palma, $24,600; and Rickenbacker, $24,000.

****Castor Oil as a Lubricant.**

Q.—Do the race drivers use castor oil exclusively in their high-speed engines, or is it compounded?

A.—Very few racing drivers use pure castor oil. In each of the big races not more than one or two drivers have used it. Nowadays, when castor oil is used, it is not compounded, but in former years it was sometimes mixed with alcohol. It may be that some drivers are secretly using their own mixing process.

Auto Club of America.

Q.—In what year was the Automobile Club of America organized, and how many cars were produced that year?

A.—On Wednesday, January 7, 1899, a public meeting was held at the Waldorf-Astoria Hotel, New York, and as a result the National Auto Club of America was chartered on the following August 6. Six hundred machines were produced in 1899.

First High Tension Coil.

Q.—When was the jump-spark coil invented and first used?

A.—In February, 1852, Emperor Napoleon of France offered 50,000 francs to the man who could produce the most important electric invention during the next five years, which period was later extended five years. This award was finally given to H. D. Ruhmkorff, a Paris instrument maker, for inventing the jump-spark coil, often referred to as the Ruhmkorff coil or high-tension coil. This coil, however, was first actually developed by Prof. Charles G. Page of Washington, D. C., following the researches of Faraday, Joseph Henry and W. Sturgeon, about 1831, and really should be more properly termed Page's coil.

First Rubber Tire.

Q.—When was rubber first discovered and who made the first rubber tires?

A.—The first mention of rubber was in 1525, when the Spaniards in Mexico saw the natives playing with balls of a remarkable elasticity. In 1770 it was suggested as an eraser for pencil marks. In 1823 Macintosh of Manchester, England, found that rubber would dissolve in benzine and began making waterproof fabrics. In 1832 the Roxbury Rubber Company was formed in Massachusetts to engage in this work and Charles Goodyear was one of its employes. Goodyear discovered vulcanization in 1835. In 1842 he began producing rubber shoes. The first use of rubber tires was when Dietz in 1835 patented a rubber cushion applied to an iron ring or tire. R. W. Thompson, an Englishman, December 10, 1845, patented the first pneumatic tire.

Right Side of an Automobile.

Q.—Which is the right side of an automobile?

A.—The right side of an automobile is always understood to be the right of the driver when seated in the car, not of the person standing in front of the car.

Garage and Limousine.

Q.—Kindly give me the derivation of "garage" and "limousine." I judge both are of French origin.

A.—Yes, both words are of French derivation. Garage is a derivation from "gare," a station or terminal for either railway trains or boats. "Garage," as a noun, means, in both French and English, a place in which motor cars are stored. The term "limousine' was originally applied to a cloak worn by the inhabitants of Limousine an old province of Central France. It was later extended to the covering of a carriage, and then to a type of motor car body with a permanent top projecting over the driver.

Pronounciation of Auto Words.

Q.—(1) What is the correct pronounciation of chassis? (2) Of Fiat? (3) Of Peugeot? (4) Has the Losier motor of the 1913 and 1914 light six, ball bearings on the main and connecting rod bearings of the crankshaft?

A.—(1) Chassis is pronounced shase, the a is like a in ask and the e is like e in event. The accent is on the first syllable. (2) Fiat is pronounced Fee-at, accent on the first syllable. (3) Peugeot is pronounced Pu-jo, the u being like u in pur and the j being soft. (4) The light six Losier did not have ball bearings on crank shaft or connecting rods.

Meaning of Words used in Connection with The Auto.

Q.—Will you oblige me with the meaning of following words I see quite often used in connection with the automobile, cardan joint, pantasote, bore and stroke, accelerator.

A.—Cardan joint is the same as universal joint. Pantasote is an imitation leather used for upholstering and tops. The bore of an engine cylinder is the measurement across the circular space in which the piston moves. It is another term for the internal diameter of the cylinder. The stroke is the length of the path through which the piston moves in the cylinder, and is exactly equal to the diameter of the circle made by the crank pin. The purpose of an accelerator is to open the throttle by means of a pedal on the foot board independent of the hand throttle. It opens the throttle more quickly than the hand throttle, hence the term "accelerator."

Water in Crank Case.

Q.—How does water get into my crank case and mix with my oil? The gasoline is strained and the lubricating oil is all right.

A.—Two things may cause the trouble; one of chemical origin, the other ill-fitting piston rings. When gasoline is burned with the proper amount of air the hydrogen and carbon of the gasoline combine with the oxygen of the air to form water and carbon dioxide. Hence, water is always one of the products of combustion and exists in the cylinder in the form of superheated steam. Ill-fitting piston rings and scored cylinders allow gas to blow by, consequently more water will condense in such engines. This is more common with six and multicylinder engines, because there is more ring surface, consequently more chance of leakage. The carburetor adjustment is also important. A mixture containing much gasoline means an excessive amount of water, just as sure as it means a formation of carbon in the cylinder.

High Altitudes.

Q.—Does the water become heated more quickly in a high altitude than a low altitude?

A.—Water boils at a lower temperature in a high altitude because the pressure of the atmosphere, which water must overcome before it can boil or change into steam, is lower in a high altitude. At an elevation of one mile water will boil at a temperature 10 degrees lower than at sea level. In crossing the Rocky Mountains the road is frequently much more than one mile above sea level and water boils away very rapidly.

*There are 3600 seconds in one hour. To find the miles per hour, divide 3600 by the time it takes to make one mile. †Figures are not now correct. **See page 918.

Use of Graphite in Engine.

Q.—Can graphite be used in an automobile engine?

A.—Yes. See page 205.

Which is the Best Car?

Q.—I am considering purchasing a car. Advise me which of the three you would advise and the advantages of one over the other—Dodge, Overland, Maxwell?

A.—Comment on relative merits of cars in this department is irregular. All those you name are good cars. I will tell you how I would settle the choice, if I were unable to decide otherwise, go to several used car concerns and ascertain which car brings the best price. This may answer your question. (see pages 527 and 528.)

Ratio of Gearing Leading Cars.

Q.—What is the ratio of gearing (high speed) of some of the leading cars?

Studebaker Four	4 to 1
Studebaker Six	3.7 to 1
Hupmobile	4 to 1
Saxon Four and Six	4.75 to 1
Grant	4.50 to 1
Reo	4 to 1
Empire	4 to 1
Haynes	4.07 to 1
Buick	3.77 to 1
Overland 86	4.01 to 1
Overland 83	3.70 to 1
Oakland Eight	4.8 to 1
Oakland Large Six	4.25 to 1
Oakland Small Six	4.42 to 1
Willys-Knight	4 to 1
Chevrolet 490	3.67 to 1
Chevrolet	4 to 1
Chalmers M. 6	3.75 to 1
Chalmers 48	4 to 1
Chalmers 40	4.50 to 1

Ratio Gearing; 1st, 2nd, 3rd and Reverse.

Q.—What is the difference in ratio of gearing on first, second and third, or low, intermediate and high, of a car?

A.—This varies slightly in different cars. The ratio on a King Eight, for instance, is: First or low speed, 14.8 to 1; second or intermediate speed, 8.7 to 1; third or high speed, 4.6 to 1; reverse, 18 to 1. See page 22 for explanation of ratio.

Meaning of 25-35; Engine Rating.

Q.—What does 25-35 horse-power mean? I note many manufacturers rate their engines with two ratings.

A.—The 25 means the horse-power acording to the Society of Automobile Engineers' formula at 1000 r.p.m. The 35 means the actual block test the engine is capable of developing at full speed. It is taken for granted that the engine will develop 25 horse-power continuously, and will stand an overload of 35 horse-power for short periods. Most electric generators will stand a considerable overload for a short period but will heat if run overloaded continuously. The same applies to the automobile engine.

Advisability of using Engine as a Brake Downhill.

Q.—I should be obliged if you will inform me whether it pays to save the brakes when descending a hill and to use the compression of the engine by switching off? Is it not correct to assume that the engine is using as much gas as though it were driving, and is thus wasting fuel? I may say, however, that the brake effect is very good, even with top gear in use. It is only when descending an unusually steep hill that there is any need to use the foot brake.

A.—It can be recommended as good practice to use the engine as a brake, provided that it draws in pure air and not mixture. This is most wasteful, as it is equivalent to having the engine running at full throttle all the time. The correct practice would be to shut the throttle and open an extra air valve which could be provided on the inlet pipe. In this way the engine serves as an economical brake, and prevents wear and tear of the regular brake shoes

Four Speed Transmission Gear Ratio.

Locomobile: Four speeds forward, one reverse; **direct on fourth.** Ratio of various speeds using 3.85 to 1 rear axle gearing are as follows:

1st speed	15.40 to 1
2nd speed	7.39 to 1
3rd speed	5.38 to 1
4th speed (direct)	3.85 to 1
Reverse	21.75 to 1

Pierce Arrow: 38 and 48 H. P. cars both have four speeds forward one reverse; **direct on fourth.** Bevel gear ratio on the 38 H. P. is 3.78 to 1 and 3.53 to 1 on the 48 H. P.

	38	48
1st speed	3.88 to 1	4.1 to 1
2nd speed	2.22 to 1	2.15 to 1
3rd speed	1.65 to 1	1.65 to 1
4th speed	direct	direct
Reverse	4.66 to 1	4.93 to 1

Winton: Model 22, 48 H. P. Car and model 22A, 33 H. P. (1916 to 1919) both have four speeds, but **direct is on third.** Rear axle ratio of model 22, 4-1/12 to 1 and model 22A, 4-8/11 to 1.

1st speed	3.29 to 1
2nd speed	1.61 to 1
3rd speed	direct
4th speed	.78 to 1
Reverse	3.94 to 1

If Engine Overheats and Piston Sticks.

Q.—If on acount of overheating a piston becomes "seized" or stuck what is best to do?

A.—See index "Seized piston."

Wire on a Magneto.

Q.—How many feet of wire is used on a low and high tension coil, and what size of wire is used?

A.—There are many thousand feet of No. 36 or No. 42 small silk covered copper wire on a secondary winding, see page 240.

Signs of Punctured Insulation.

Q.—What are the signs of punctured insulation in the high tension winding of a magneto armature, and how would you test?

A.—If the insulation is punctured on the high tension wire winding, the result would be that there would be a weak spark, and finally where insultation was punctured and bare, a spark would very likely jump through to other winding unless the top layer was well insulated, and eventually short circuit and put the armature out of commission altogether; but the first noticeable result would be a very weak spark or no spark at all. See pages 235, 249 and 253, "testing a coil."

Cause of Noise; in Timing and Magneto Gears.

Q.—I have a ——car fitted with magneto ignition run by gears. When engine runs slow or is slowly revolved, these gears seem to kick back and forth and make a lot of noise, what is the cause?

A.—The cause of this is worn gears. Very likely on the magneto side, and this "pull back" as you call it, is occasioned by the pull of the armature of the magneto. If you have ever turned over the armature of a magneto, you know how it jumps at a cerain point, which is caused by the pull of the magnets on the armature.

Now, when engine is running slow, and this point is reached, this is what has a tendency to

Replacing Ring Gear on a Differential.

Q.—When replacing a ring gear on a differential is it best to hot rivet or cold rivet same?

A.—Either the cold or hot rivet can be used. At the factories where they have special power riveting machines the work is done with cold rivets and in one-tenth of the time.

The average blacksmith or repairmen, however, will probably find it better to heat the rivets, which is often done where there is only a hammer to do work with.

In placing a ring gear on a differential one of the greatest causes of noisy gears is due to the fact that the differential flange to which the ring gear is attached is often out of true and should be carefully trued up before fastening the ring gear to it.

pull the gears, and if the gears are worn, they will be noisy.

It is advisable to put in a new idler gear, and a new magneto drive gear.

When new gears are fitted, sometimes they make a great deal of humming noise. This noise, can sometimes be taken out by placing oil on the gears and holding "tripolite" on them while they are in motion. (Be sure not to get any tripolite on the bearings.)

The Spark—Why Blue or White.

Q.—Why is it that some coils give a thin blue spark and others a white thick one? I believe it is on account of the winding being burnt in some place or the insulation injured—am I right?

A.—Coils wound for low voltage and large amperage give fat red spark.

The Bosch Magneto Co. describe it as the "arc-flame." Weak or damaged coil will give thin spark, but will not jump a very wide gap.

Sparking Across Safety Spark Gap.

Q.—Why is it that a magneto and coil, sparks across the "safety spark gap" irregularly, when the engine runs slow, but stops when speeded up?

A.—Expansion of surplus gas, causes excess compression through which spark will not jump.

If Battery Gives out on Road.

Q.—If batteries run down and I have no other ignition electric source what would I do?

A.—Try nearest farm house and borrow or buy the telephone batteries.

Magnet Lifting Power.

Q.—Should the magnets of a magneto lift a weight of from 10 to 20 lbs. singly or all together?

A.—If a magnet is hung up and pieces of metal added to it from time to time, it will take on in this way two or three times as much as it would carry if required to lift the load at once. A single magnet will lift from 4 to 6 lbs. in normal condition.

Locking a Car.

Q.—I understand it is not a good idea to lock the wheels of a car in the down-town district, because the fire department might need to move car in case of fire. What method of locking a car would you recommend?

A.—If you have a Ford, use a K. W. ignition switch with Yale lock which can be secured at any supply house. Otherwise, use a secret plug switch, placed where it will not be seen, to open the ignition circuit, or close a padlock on the spark and throttle lever to lock it to the web of the steering wheel. The latter arrangement however, is not altogether practical if there is an accelerator.

Right of Way; Wagon or Auto?

Q.—If an automobile is back of a wagon as the wagon is going the same way, is it necessary or does the law require that the wagon give the auto the road so he can pass?

A.—In the city an ordinance requires all slow moving vehicles to keep to the curb side of the street on the right, and faster vehicles to pass in the center to the left of the slow vehicle. On country roads, section 8 of state automobile laws, provides that anyone driving a motor car who overtakes any horse or animal being ridden or driven, the rider or driver of the animal shall turn to the right side of road to permit free passage on left side.

Right of Way on Cross Streets.

Q.—Which car would you say had the right of way, one coming out of a cross street onto a thoroughfare, or the car on the thoroughfare?

A.—A car coming out of a street to your right has right of way over you, as you have over the car coming out of a street to your left. See chart 218.

Greatest Number of Miles of Road.

Q.—What state has the highest mileage of roads? Are the roads of Missouri being improved?

A.—Kansas has the greatest number of miles of road; 111,536. Missouri comes second with 108,000; Iowa third, with 104,000; Illinois fourth, with 100,000. In 1912 Missouri had the greatest mileage. Out of the 108,000. miles of Missouri roads, 4750 miles are improved, 103,250 miles are dirt roads and 3500 miles are gravel. Missouri made no improvements at all in 1914. Indiana however, spent $17,000,000 in 1914 for improvements; Iowa, $11,000,000; New York, $14,000,000, and very near all other states made improvements costing from $156,000 to $9,000.000

Re-Painting a Radiator.

Q.—Will you suggest a good method for re-painting a radiator?

A.—The best plan is to take the radiator to a specialist, who will dip it. If you prefer to do the work yourself, remove the radiator, lay it flat and pour upon it a mixture of lampblack and turpentine made so thin that it will run onto the sides of the cells. Wipe off any of the mixture which may splash on the painted part of the radiator before it dries. At first the color will appear gray, but will soon darken (see page 194 and index.)

Muddy Radiator; Cleaning.

Q.—The front of my radiator is muddy. What is the best plan for clearing it?

A.—When it is necessary to clear the radiator spaces of accumulated mud, you should flush the radiator from the rear, not from the front. In that way you avoid getting water into the magneto or ignition system, which is often short-circuited when the moisture enters it.

Front Axle Bent.

Q.—I bent my front axle, but local blacksmith is afraid to try to bend it back, as he says it was made of special steel.

A.—Axles are usually made of nickel steel. To straighten, heat to a cherry red, then straighten. If heated hotter than a cherry red all the nickle will be taken out of the steel.

Side of Street to Stop on.

Q.—If a tire is blown out and it is necessary to stop, what side of the road would I stop on and leave car?

A.—Obey the traffic law, see rules of the road.

Engine Uses Too Much Oil.

Q.—I have a car that has always used too much cylinder oil. I recently had nonleaking piston rings applied, one in each piston, although the old rings were good and the cylinders were not worn, the tool marks not being effaced. Can you give me a remedy for the oil getting by the piston rings and fouling the spark plugs and valves?

A.—It is possible that the cylinders have been worn out of round or that the pistons fit poorly. A good mechanic should be able to micrometer the pistons and cylinders and determine whether this is the trouble. If the cylinders are in good shape and the pistons fit poorly the remedy is to install oversize pistons. If the cylinders are scored the only remedy is reboring the cylinders and fitting new pistons, see also page 202.

Oil Leaks from Bolt Holes of Crank Case.

Q.—How can I stop the oil from leaking through the bolt holes of the lower crank case cover and out of the fly wheel housing drain plug?

A.—Back the studs out about ¼ inch and wind five or six turns of cotton twine around it between the lock washer and the case cover. This will positively stop the leak through the stud holes. However, we are inclined to think your oil is running down the side of the case from some other point. Perhaps the valve push rods. Wipe all oil off thoroughly and run the engine idle at about 600 or 800 r. p. m. and see for sure where the oil comes from.

Causes of Vibration of Engine.

Q.—About a year ago my engine began to vibrate, at around about 25 miles per hour. It did not vibrate when new, and I would like to know what causes vibration. It operates O.K. outside of that. Bearings are O.K. In fact, it runs just as smooth as when new, except that it vibrates. Will a crank shaft that is out of line or out of balance cause this?

A.—Vibration is due to forces being out of balance or unequal, for instance; engine loose on frame, uneven compression, weak explosion in one or more cylinders, due to leaky rings or valves or too much oil in that particular cylinder.

Defective spark or plug. Sprung crank shaft. Clutch out of balance. New full size bearing and shims on one crank throw, and the old worn or lighter bearing with shims or liners removed on the other crank throw. Different weight pistons. Front wheels out of true, rim out of plane with spokes. Would suggest throw-out clutch and run engine idle at different speeds.

How to Determine Correct Carburetor Mixture.

Q.—How do you determine when the carburetion mixture is correct by the color of the flame from the relief cock and what is the cause of so much smoke coming out the exhaust?

A.—See page 169, 855.

Kerosene for Cooling.

Q.—Would kerosene make a good substitute for water for use in radiators of cars during winter?

A.—Objections are the odor of heated kerosene; when heated kerosene evaporates and is liable to cause a fire if near a flame; on warm days in winter there is a tendency for engine to heat on account of difference in co-efficient of heat of kerosene and water or alcohol; kerosene rots radiator tubing and will also deposit a greasy mist over car. Gas is also liable to form and cause expansion and bulging of radiator.

Kerosene and Gasoline.

Q.—Is it possible to use kerosene in the carburetor of an automobile?

A.—Yes, but it is necessary to start on gasoline. Many experiments have been made to determine the possibility of using low-grade fuels like kerosene. They have shown that these fuels can be used under proper conditions, but that it is difficult for the ordinary motor car user to get satisfactory results from them. Gasoline is volatile; kerosene is not. Clogging up or loading up takes place whenever the engine is too cold, after coasting or standing. Often when the engine is throttled the fuel seems to condense, load up the intake pipe and occasionally flow back into the carburetor. When the throttle is then opened this excess fuel is drawn into the cylinders, as shown by clouds of smoke and carbonization results. Kerosene requires some outside heating device to vaporize it. Experimenters are working on this problem of heating and no doubt will succeed in time. "Necessity is the mother of invention," see index.

Gasoline and Kerosene.

Q.—What proportion of gasoline and kerosene will work together?

A.—The proportion of kerosene which can be used with gasoline on some carburetors is 1 gallon of gasoline to 3 gallons of kerosene. But starting will have to be with gasoline. Better have extra tank of gasoline to start on until engine warms up, see index, "kerosene carburetion."

Low Grade Gasoline.

Q.—Is low grade gasoline suitable for automobiles?

A.—The present day gasoline for automobiles, is usually in three grades, called No. 1, 2, and 3. The lowest grade No. 3 is used quite freely, but if its sets for a week unused you will likely find that all the coal oil in the gasoline, which is the heaviest, has settled at bottom of tank and hence difficult starting. If you stir it up or take an oil gun and draw off some from top and put in carburetor to start on it will probably help. See page 161.

Why Engine Runs Smoother at Night.

Q.—I have always noticed that my engine runs smoother or better at night. Why is this?

A.—Experiments with stationary internal combustion engines have shown that water vapor—steam—injected into the combustion chamber gives an advantage, but the reason is not clear. On the same principle an engine runs better at night when there is more moisture in the air. It may be that the additional oxygen supplied by the small amount of water aids in the combustion of the fuel.

Ether and Gasoline.

Q.—What proportion of ether can be used with gasoline to increase power and speed for racing?

A.—See index for ether.

Carburetor Drips.

Q.—When I stop my engine I notice gasoline continually drips from the bottom of carburetor. What causes this?

A.—The float needle valve is probably the cause. Remedy: Put in a new one. To test: Remove carburetor from engine, then test the float needle valve by pouring gasoline into the float chamber. If gasoline drips from needle valve then the trouble is in the needle valve and a new one must be fitted. If it does not drip at needle valve, but comes from the jet, then the float is set too low—slightly raise the float. When refitting carburetor back on engine be sure a tight fit is made where joined to inlet pipe, otherwise an air leak will interfere with carburetion. Leather makes a good gasket for carburetor. See pages 164 and 166.

Leaky Carburetor Float Needle Valve.

Q.—How is a leaky carburetor float needle valve ground to keep it from leaking?

A.—If made of steel use crocus or a fine grade of emery with a little oil and grind the needle to a tight seat. If brass and the needle is tapering lightly tap it with a hammer on its seat, then grind a tight seat, using oil. To test after grinding, pour in gasoline and note whether it drips. A new needle valve is the best. See page 167.

Out of Gasoline on a Country Road.

Q.—If I was in the country and run out of gasoline what would I do to get back?

A.—Send for gasoline if none can be secured at a farm house. If kerosene could be secured in the vicinity, which is more likely than gasoline, then drain tank of what little gasoline is left, unscrew carburetor float top, pour in until carburetor chamber is full. Mix remainder with kerosene and pour into tank. Start engine on the gasoline in carburetor, then when started it ought to run on gasoline and kerosene mixed. The greatest amount of kerosene to gasoline which can be used on the average carburetor is 3 to 1.

Note: this will not work satisfactorily unless intake is heated, see page 157.

Cause of Carburetor Freezing.

Q.—My carbureter froze up during the last cold weather, and I could not start my engine. What causes this?

A.—The presence of an abnormal amount of water in the gasoline is the trouble. Garage proprietors say this trouble was never so pronounced as at present, and they attribute it to the adulteration of oils, believed to be carried on to a greater extent this season than ever before. See page 161.

Gasoline Consumption.

Q.—Does it take more gasoline when running slow and in congested traffic than when running on country roads?

A.—Yes; this fact was demonstrated by a Marmon car recently. In the business district of Chicago ten and one-half miles per gallon was the average, whereas on streets where conditions were similar to country roads the same car did fifteen and three-fourths miles per gallon. Most likely due to the momentum of car in the one case, and absence of it, in the other.

***Freezing and Boiling Point and Specific Gravity of Water, Alcohol, Kerosene and Gasoline.**

Constants	Water	Wood Alcohol	Ethyl Alcohol	Denatured Alcohol Formula #1	Kerosene	Gasoline
Freezing Point	+32°F 0°C	−144°F −98°C	−202°F −130°C	−200°F −129°C	Does not have a definite point Solidifies about −60°C	−202°F −130°C
Boiling Point	+212°F +100°C	153°F 67°C	173°F 78.4°C	171°F 77.4°C	387°F 197°C	173°F 78.5°C
Specific Gravity	1.000 at 0/4°C	.789 at 0°C	.8002 at 0°C	.8164 at 15°C	.815 at 15°C	728 at 15°C

*Mercury freezes at 38.7° below zero and boils or gives off gas at 357° above zero, Fahrenheit.

1 lb. of gasoline of 58 specific gravity is approximately 8 tenths of a pint. A gallon of gasoline (58 s. g.) weighs approximately 6.6 lbs. See pages 587, 861 for number of B. T. U.'s to a lb. of gasoline.

Straining Gasoline.

Q.—I noticed an article in some paper recently that by pouring gasoline through a chamois in a funnel, electricity was generated, set fire to the gasoline and severely burned a man pouring the gasoline. Do you think such a thing possible?

A.—So some one claimed, see page 162.

Soldering and Repairing Radiator Leak.

Q.—What kind of tool or torch can be used for repairing radiators? I find it hard to get at the small openings in a radiator with a common soldering iron.

A.—Procure at some electric establishment a heavy piece of copper wire. Hammer it out to fit the place you desire to solder. After soldering, place radiator in a vessel of water. Close up one end of the radiator and plug the other end. Place a small piece of tubing through one of the plugs and pump air into the radiator. Note whether it leaks. If it does, mark the place—scrape and resolder. See pages 191, 194, index.

Will a Clincher Tire fit a Q. D. Rim.

Q.—Will the old-style plain clincher tire fit a quick detachable clincher rim? Also let me know whether a straight-side tire will fit a clincher rim?

A.—Yes, a plain clincher tire will fit a quick detachable clincher rim, but a quick detachable clincher tire will not fit a clincher rim. It may be forced on, but it will be quite a job, and the probabilities are the bead would be damaged. A regular clincher tire has a flexible bead. A quick detachable tire has a hard bead. I have seen a straight side tire on a clincher rim, but it is not practical. See page 553.

Overloading of Carburetor.

Q.—(1) When descending grades with the throttle closed, the engine shows a tendency to overload, and appears to start with difficulty when the throttle is reopened. (2) What is the cause of a decided rumbling noise in the transmission, when the machine is ascending a grade on intermediate gear?

A.—(1) Too much gasoline. Change the low speed adjustment. May be the float is too high, if cutting down the gasoline supply does not remedy the trouble. The engine will pick up sluggish if there is too much gasoline, therefore the adjustment ought to remedy this trouble also. You did not mention the make of the carburetor hence definite directions cannot be given. (2) All second-speed gears make more noise than the high gear. May be worn gears or bearings, or both are responsible.

Metering Pin and Dash Pot.

Q.—I notice the term "metering pin" and "dash pot" used in speaking of carburetors. What are they for? A.—See page 151.

Proportion of Air to Gasoline.

Q.—What proportion of air is used with gasoline in carburetors?

A.—The best explosive mixture when maximum power is desired with the gasoline commonly used is 14 parts of air to one part gasoline. From this the mixture can range to 17 to 1, the latter for maximum economy—see page 142.

Mixture Which Heats.

Q.—What kind of mixture heats engine most, rich or lean?

A.—Lean mixture under load. Rich mixture running light—see page 169.

Different Size Spark Plugs.

Q.—How many sizes of spark plugs are there in general use? Why don't manufacturers use one size plug? A.—See pages 235 to 239.

Spark Plug Points; Correct Distance to Set.

Q.—What is the correct distance apart to set the points of spark plug and interrupter?

A.—See pages 235, 233, 219, 297, 298.

Distance the Spark will Jump.

Q.—If a spark will jump ¼ to ⅜ inch outside of cylinder what space will it jump inside?

A.—The spark which will jump from one-quarter to three eighths of an inch on outside of a cylinder, will jump one-sixteenth of an inch inside under compression, (see page 236). A spark which would jump no further then one-quarter of an inch on the outside of the cylinder has worked, but we would advise that a coil which jumps three-quarters or one inch for general use, because, if you use a low grade gasoline it is harder to ignite than a high grade.

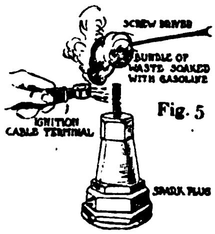

Fig. 5

Substitute for a Match.

A piece of waste or cloth dampened with gasoline is tied to a screw driver. One of the ignition cables to a spark plug is removed and placed near enough to the electrode so that the spark jumps across. The cloth is introduced between the two and the spark will ignite the gasoline.

Engine Continues to Run.

Q.—I use a magneto and battery for ignition. In running on the magneto, when I turn off the switch the engine continues to run. Why is this?

A.—The ground wire from your magneto to the frame of your car is evidently broken. In magneto ignition the switch closes or short circuits the primary winding through this ground wire. Therefore if the ground wire is broken the current could not be short circuited and the engine would continue to run—see page 275 and 276, fig. 1.

Spark Plugs Indicate Condition of Valves.

Q.—Can you tell by the condition of the spark plugs whether the valves need grinding?

A.—Yes, if the end of the spark plug is oily it indicates too much lubricating oil or leaky piston rings. If black soft soot like that which accumulates in a lamp chimney, this indicates that too much gasoline is being fed to the cylinder through intake, causing too rich a mixture. This may come from improper carburetor adjustment or an air leak in intake manifold. If the ends of the plugs are oily and sooty, this would indicate that the valves leak, as this permits burnt gases being drawn into the mixture, which would result in poor combustion and lack of pressure in cylinder, which would permit oil to pass and foul plug.

Telephone Generator.

Q.—Can I use a telephone generator taken from an old phone for ignition?

A.—No; this generator generates a high voltage, but practically no amperage or quantity of current at all. If you were to run it at high enough speed, say 3000 revolutions per minute, and had a proper transformer or coil to "build up" the current, that is, to reduce the voltage and make a higher amperage, it might be used with the make-and-break system of ignition.

Battery Jar Trouble.

Q.—I have an Exide storage battery which has two cells leaking. Can you inform me what a hard rubber cell may be patched with, in order to stop leakage of acid?

A.—A hard rubber jar cannot be patched. A new jar will be necessary, which can be secured at an Exide storage battery station. A new jar will cost about $1.75.

To Tell (N) and (S) Pole of Magnets.

Q.—How do you tell the north and south poles of magneto magnets?

A.—To tell the positive and negative poles; north pole is positive + and south pole is negative —. To find north and south pole; use a compass, as explained on page 303.

A "Twin Two" Cylinder Engine.

Q.—Is there any make of car using a four-cylinder "twin two"?

A.—The Leon-Peugeot, a French car, uses this type of motor. There are two cylinder blocks placed 10 degrees apart from the vertical.

Missing on a 2 Cylinder Opposed Engine.

Q.—I have an I. H. C. Truck, which has a two cylinder opposed type engine. The back cylinder misses fire every two explosions. If I short circuit the front plug and give a little more gas, then it does not miss, but when I let the other cylinder work, it misses.

A.—From this meager information it appears that one cylinder is getting too much air and one too much gas. The one which misses appears to get too much air, either through a worn valve stem guide, a worn stem, or where manifold connects with the cylinder. In the manifold, near the cylinder which does not miss, drill a small hole and put in a pet cock, then gradually let in air to equalize. This cylinder evidently gets the richer mixture and needs air.

Laps of Power Strokes on a Twelve.

Q.—Do two cylinders work together all the time on a twelve-cylinder engine?

A.—On a twin six-cylinder (twelve-cylinder engine) there are twelve periods of 14 degrees when three pistons are working together, and twelve periods of 46 degrees when two pistons are working together. This naturally gives steady power or torque. See pages 126, 135 and 136.

Why Racing Engines 4-Cylinder.

Q.—If the eight and twelve cylinder engine gives more flexibility and is considered the coming car, why is it all the racing cars are four cylinder?

A.—Four-cylinder engines are used for racing cars, because there is no advantage in using more, when a smaller number will do the same work. The six, eight and twelve cylinder engines are coming into use because they give more flexibility. You can run a car with a six, eight or twelve cylinder engine at very low speed uphill or in traffic without changing gears. In a race the desideratum is speed, and flexibility which is an essential in the ordinary use of a car, is of no advantage.

The special designed (overhead valve) 12 cyl. Packard engine holds most of the speed records now. Therefore when carefully designed for racing, it is evident that the multiple cyl. engine is also suitable for racing.

Another reason the four cylinder engine is used extensively for racing is on account of the higher thermal efficiency of larger cylinder, this being due to the fact that there is less wall area in proportion to the volume, and furthermore, the friction is not as high in a four cylinder motor as it would be in a motor of more cylinders. Furthermore, a four cylinder motor is shorter and lighter than either a six or 12 cylinder, probably not any shorter than an 8, but the weight per horsepower would be less in a four than in an eight.

Racing engines often use one or two piston rings so as to facilitate more perfect lubrication, perfectly tight compression being not so necessary for high speed motors as for low speed ones, furthermore, good compression is more necessary for good carburetion at low speeds, while it is not so noticeable at the higher speeds.

Diesel Engine Principle.

Q.—What is the principle upon which the Diesel engine is operated? I understand no spark at all is used for ignition. How is the gas fired?

A.—The principle of the "four cycle" type of Diesel engine may be briefly described as follows: On the first or down stroke of the piston the Cylinder is filled with air at the atmospheric temperature and pressure. No fuel is introduced. On the second stroke, the piston travels up and the air, drawn in during the preceding stroke, is compressed to about 500 pounds per square inch, resulting in its temperature being raised to about 1000 degrees Fahrenheit, or sufficient to ignite any liquid fuel. Then the fuel valve opens and a measured quantity of fuel, usually oil, is injected into the cylinder through an atomizer. The atomized fuel is ignited by the high temperature of the air and the power stroke follows. On the fourth or exhaust stroke, the piston travels up and the burnt gas is expelled through the exhaust valve. The Diesel engine requires no ignition system and uses the cheapest of petroleum, crude, fuel oils or tar oils.

Speedometer Gearing.

Q.—Could the same speedometer be used on a 30x2½ tire that is used on a 30x3 tire?

A.—Yes. This will not necessitate a corresponding change in gears. It is only necessary that the number of teeth in the road wheel gear, always be equal to twice the number of inches, in the diameter of the wheel.

Knight Engine, its history.

Q.—Has the Knight engine been tried out fully, or is it still an experiment? What foreign manufacturers use it?

A.—The Knight sleeve valve type was invented in Chicago in 1903. The engine was under experiment until 1905, at which time it was given severe tests in Elyria, Ohio. In 1906 Charles V. Knight submitted his engine to the largest motor car company of England, the Daimler Company. After tests, the Daimler Company adopted it. Other leading European automobile manufacturers who adopted this type of engine are the Panhard Company, France; Mercedes Company, Germany, and the Minerva Company, Belgium.

Thermal Efficiency.

Q.—What is meant by "thermal efficiency"?

A.—Thermal efficiency is the ratio of work actually done, when expressed in heat units, to the total heat supplied in the fuel that enters the combustion chamber and is always less than 100 per cent.

For example: Suppose we introduce a lb. of gasoline (approximately .8 pint) into a cylinder. This amount of gasoline contains about 19,000 B. T. U.'s (see page 861). Now suppose we received from the crankshaft, during the consumption of this pound of gasoline, an amount of work equal to 4,424,600 ft. lbs. of work. One B. T. U. is a unit or quantity of heat, therefore energy, and by experiment has been found to be equal to 778 ft. lbs. The 4,424,600 ft. lbs. of work we received from crankshaft could be expressed as

$$\frac{4{,}424{,}600}{.778} \text{ or } 5700 \text{ B. T. U.}$$

The thermal efficiency of the engine would then be 5700 B. T. U. divided by 19,000 B. T. U. of 30%, thermal efficiency. (See also page 535.)

Wind Resistance.

Wind resistance increases in proportion to the "square" of the speed: thus at 20 miles per hour it is four times what it is at 10 miles, and at 30 miles per hour nine times, and so on. (See also page 760.)

Cut Cylinders.

Q.—What is the process for grinding out worn or cut places in cylinder?

A.—If a worn place is in the cylinder, then you must first ascertain if you have thickness enough, or wall to grind or bore or ream the entire cylinder down to the depth of this worn place, and then fit in piston, slightly larger, or large enough to take up this distance, (see instruction 46.)

Fire Truck Engine—How Cooled.

Q.—How does the engine on an automobile fire truck cool itself when the engine is running continuously for long periods with car standing, which is often the case at a fire? My engine would soon get hot and the water in the radiator would steam.

A.—There is a cooling line from the discharge side of the main pump directly into the water manifold. This is a ¾-inch line and is controlled by a gate valve which enables the operator to keep the engine at any desired temperature. An overflow on the radiator allows this cooling water, which amounts to 8 to 10 gallons per minute, to pass off.

Why Valves are Called "Poppet Valves."

Q.—Why are the inlet and exhaust valves on the gasoline engine called "poppet" valves?

A.—The valve is continually popping up and down as the cam turns, which may account for the name "poppet." However, the word poppet probably is a corruption of the name puppet, applied to this type in England, on account of its resemblance to the popping up and down of the puppets in the old-time Punch and Judy shows.

Lynite Pistons.

Q.—I notice "lynite" pistons are being advertised for Ford engines. What is "lynite"? What are the advantages?

A.—Lynite is an aluminum alloy of French origin. It is produced in America by the Aluminum Casting Company of Detroit and Cleveland. Pistons made of this material are one-third the weight of cast-iron pistons. The manufacturers claim greater reciprocating motion, which allows quicker acceleration, less friction and less vibration. The McQuay-Norris Manufacturing Company of St. Louis controls the exclusive sales of Lynite pistons for Ford cars, which are sold in sets.

Annular Ball Bearings.

Q.—I often hear the term "annular" ball bearings. What kind of bearing is this?

A.—Two types of ball bearings are in general use on motor cars, the "annular" and the "cup and cone." Annular means "ring shaped." The balls on an annular bearing move around the center of the inner race. They carry the load radially and do not take care of the thrust load. The cup and cone type of ball bearing can be adjusted and will carry a thrust load as well as a radial load, see page 36.

Ford Magnets—how placed.

Q.—(1) When the magnets are bolted in flywheel of a Ford magneto, which poles go side by side? (2) Also, when not on flywheel just lying loose, should they have keepers across ends? (3) What weight should one of these magnets lift when fully charged?

A.—(1) N. and S. (2) Yes, by all means. (3) 1¾ to 2 pounds when fully charged.

Old Tires, Price Of.

Q.—What price ought I get for my old tires and tubes?

A.—The average price paid is 5c for old tires and 6c per lb. for tubes.

Grades, How Calculated.

Q.—Would thank you to explain how grades are calculated. How would you determine a grade of 20 per cent?

A.—A grade 1 in 5 equals 20 per cent; a rise of 1 foot in a distance of 5 feet horizontally; 1 foot is 20 per cent of 5. In other words, if the distance traveled is 100 feet in a certain direction and the rise is 20 feet, this would be a 20 per cent grade, see chart 226-A.

Why Not Solid Tires?

Q.—Why can't I put solid rubber tires on my automobile and save tire expense?

A.—Because cars that run above fifteen miles per hour would soon rack to pieces. The vibration would be too great, and while there might be a saving on tires the cost of repairs on the car would be far greater. Solid tires at high speeds are also dangerous, owing to greater tendency to skid.

Undersize Tube.

Q.—Could a 32x3 tube be used in 32x3½ casing?

A.—It is not advisable. An inner tube should fill the casing without being greatly distended. As a rule the so-called "over-size" tubes, such as 33x4, are best for use in casings 32x3½.

Wheels out of Line Cause of Tire Trouble.

Q.—My tire on the front right wheel has worn considerably. The tire man said it was caused by my wheel being out of line. How will I line it up properly?

A.—See chart 279.

Why Right Rear Tire Wears Most.

Q.—I have always heard that the right rear wheel carries more load and hence the tire on this wheel undergoes more wear. Why is this?

A.—This is due to the crowned or oval surface of the road, and because you drive on the right side of the road there is more weight on the right wheels. This causes the right tires to grip the road harder. Hence when brakes are applied suddenly the rear wheels often slide, wearing off the rubber.

Valve Timing of Hupmobile.

Model	In. opens deg.	in.	In. closes deg.	in.	Ex. opens deg.	in.	Ex. closes deg.	in.
20....	25 or	3½	35 or	4 15/64	40 or	4 27/32	20 or	2 27/64
K&N..	on top		24 or	3¼	39 or	5 9/32	5 or	1 1/16
32....	25 or	3 9/32	35 or	4 37/64	40 or	5 15/64	20 or	2 [illegible]/64

Position for Spark to Occur.

20....3° or ⅜" after top, retarded.
K&N..2" before top, igniter in neutral position.
32....15° after top or 1 5/32", spark retarded.

Skidding.

Q.—I have a great deal of trouble with my car skidding. What is best to do, when one skids, throw on the brake?

A.—To control a skid it requires quick perception of the coming deviation, and prompt action to counteract it. Brakes are usually unsymmetrical in their effects, and putting on the brake usually increases the skid, especially if the power is left on. The first thing needed is to declutch and the next is rapid and intelligent use of the wheel.

Brake Bands, how to clean.

Q.—What plan is best to cause brake bands to hold. Have tightened them, but they still slip?

A.—A syringe full of kerosene squirted on Raybestos brake bands occasionally will help them grip the drum. The kerosene has a tendency to dissolve the oily matter on the bands, leaving the surface clean. Squeaky brakes are also remedied by the use of kerosene.

Frosting Compound.

Q.—Will you suggest a quick method for dimming headlights?

A.—Five cents' worth of epsom salts dissolved in a teacup full of water provides the neatest and most efficient headlight dimmer for automobiles, so far proposed. The solution is used on the inside of the headlight glass, where it is allowed to evaporate. The result is a beautifully frosted lens, the frosting on which lasts for several months.—Scientific American.

Painting Cylinders and Manifolds.

Q.—What can be used for painting cylinders and exhaust pipes, or, in other words, a paint which will resist heat?

A.—You can secure these paints from supply houses. If you prefer mixing it yourself, try the following: For cylinder—8 ounces white lead in oil, 6 ounces boiled linseed oil, 2 ounces turpentine, ½ ounce lamp-black. This will make up about 1 pint. This ought to be sufficient for a six-cylinder engine. If too heavy, thin with turpentine. For the exhaust manifold I know of nothing better than aluminum powder mixed with bronzing liquid, and even this will peel off in time. See page 509.

White Smoke.

Q.—I have an Auburn car, about 1910 model, which has a discharge of white smoke, which comes out of crank case, through the breather pipe. This discharge resembles steam and comes out in puffs like the exhaust from a steam engine. The discharge is irregular, and occurs after engine is warmed up.

A.—Your trouble would appear to be worn or leaky piston rings. They evidently permit oil to pass into the combustion chamber. They also permit the compressed charged to pass from the combustion chamber to crank case of the engine

See page 509 how to make paint for inside and outside of tires.

and thence out the breather pipe. The fact that this occurs more when the engine is warmed up than at any other time is due to the fact that your oil evidently thins down more when it is warm. Therefore it is easier for the oil to pass the ring. I would advise that you have your rings examined, and if not worn, use heavier and better oil. Also examine the valve tappets to see whether they are opening the valves as they should. Also see if your valves are opening and closing properly.

Tires for Electric Vehicles.

Q.—Is there any difference in the rubber casing used on electric cars and those used on gasoline cars? If so, what is the dfference?

A.—Quite a number of electric vehicles use the "cord tire," which is higher in price and stronger. This is due to the fact that an electric vehicle is much heavier on account of the batteries. Many of the electric vehicles use what is called the "Motz tire" with a cushion effect, and which is a solid tire. Solid tires, however, skid a great deal and are really dangerous to use on any type of high speed pleasure cars. Solid tires are not suitable for cars traveling over eighteen miles per hour, and are really injurious to batteries of electric vehicles, as the vibration has a tendency to jar the paste loose from the plates, and new batteries are more expensive than cord tires.

*Useful and Instructive Hints and Suggestions.

Heavier oil in old cars. The engine of a car that has been run for two or three years will give better delivery of power if you will use heavier oil than was at first intended for it.

Clean it out. The crank case oil reservoir should be occasionally cleaned out by flushing it with kerosene, and churning it up well by running the engine idle for two minutes. Drain oil and kerosene and put in fresh oil, otherwise the kerosene will thin the oil and cause burnt bearings.

Oil for the timer. Pure castor oil makes the best lubricating material to use in the timer.

Dry bearings. One source of insufficient lubrication of bearings is sometimes found to be clogged grooves in the bushings. Sediment will accumulate in the grooves which are intended to carry the lubricating oil, and shut off the supply. An excess of graphite will often produce this effect.

"Loading up." Gasoline leaves the carburetor as a spray of liquid. In the intake manifold it vaporizes and becomes mixed with air. When vaporization does not take place rapidly enough, or when too much gasoline is sprayed into the manifold, the liquid will accumulate on the sides and run back into the carburetor. To get best results the intake manifold should be protected from the cooling effect of the fan, and should be warmed by a by-pass conveyor of heat from the exhaust. When the gasoline in liquid form runs down into the air inlet of the carburetor the mixture will be irregular and uncertain.

A test to locate trouble: When the engine starts hard, and you are uncertain whether the fault is with the ignition or the mixture, open the throttle wide and spin the engine with spark off, then turn on the spark and the engine should start, if the spark is correct, on the first half turn.

To keep glass on windshield free from snow or rain. See foot note—bottom of page 508.

Keeping the engine warm: An ordinary carbon-burning foot-warmer, placed under the hood, will keep the engine warm for hours. A blanket over the hood will help it.

The proper way to prime: There is a "best" way to prime your engine to make it start easy. The priming cups usually furnished on top of the cylinder hold just the right amount of priming fluid to do the work. If more than that amount is placed in the cylinder the mixture may be too rich and the starting be difficult instead of easy. With stop-cocks closed, fill the cups with a priming fluid consisting of half gasoline and half ether, then open cocks and allow the fluid to run down into the cylinders.

To lock your car: A piece of trace chain covered with rubber hose and a good pad lock will lock your car so that it can not be run or drawn away. Put the chain around the frame and between spokes of front wheels. It is also a good security for spare tires.

For gasoline leaks: Hard soap, moulded around a leaking place, will serve well as a temporary repair. Wrapping with tire tape will make it more permanent.

Automobile headache: Ask the druggist to put up a few number one capsules filled with three-fourths acetanalid and one-fourth citrated caffeine. Two of these capsules half an hour apart will relieve almost any headache quickly if the stomach is not full of food. While not harmless in over-doses, two may be taken inside of one hour with perfect safety. Large doses will make the lips look blue, and this effect is to avoided.

Refreshing slumber: Fifteen grains of Trional powder taken in a little sweet milk at bedtime, after a long drive, will give refreshing sleep with no harmful result.

Benzol is a promising motor fuel. It is a by-product of coke. It contains the same elements as gasoline, but the chemical formula is slightly different. In England it is used to great extent for fuel, also for explosives, dyes and chemicals. All gas plants in England are being equipped to produce benzol. It is stated that experiments with the material are being made in the United States.

Cleaning spark plugs: The porcelain of a spark plug may be made clean and almost equal to new by soaking it in carbon disulphide. (also see page 592.)

Burning out the coil: When the spark gap of a plug is too great there is danger of burning out the secondary wire of the coil from the heat, due to great resistance.

A spark plug should not be so tight a fit in the cylinder that it cannot be screwed in with the fingers for at least two-thirds of the thread. Otherwise there is a risk of a cross-thread or badly-cut thread jamming tight.

The threads of sparking plugs, valve port caps, and exhaust pipe connections should occasionally be brushed over with some powdered graphite. This prevents seizing or binding of the threads from the oxidising action of the hot gases.

Wire efficiency: Ignition wire efficiency is not always determined by the thickness of the insulation. This is particularly true of secondary wires. It is, of course, true that insulation should be of good quality, but unnecessary thickness increases the static capacity, a condition to be avoided.

Corroded battery terminals: A little hard grease on the thumb nuts that make the battery connections, will prevent their seizing from acid corrosion.

An emergency: Nine miles from town the dry cells exhausted so that they would not start the engine. I borrowed the telephone cells of a near-by house, started the engine, and returned the cells while engine was running idle.

Dry cells in winter: If you use five dry cells in summer for starting purposes, you had better couple up seven for winter use, as the cold renders dry cells less efficient.

*See page 524 for some of the Questions sometimes asked by the State Examining Board and Instruction 46A to 46D for Useful Devices for the Repair Shop and Repair Shop Hints and Suggestions.

Storage battery connections: Often the unsatisfactory service of a storage battery is due to imperfect connections. Where the battery is kept in a steel box great care is needed to keep the terminals from touching the metal when the lid is closed. Even an occasional touch when the battery is jarred will run the current down rapidly. The connections should be wrapped well with tire tape, and the metal box kept away by packing with rubber. An old inner tube makes the best packing.

Adjusting electric bulbs: If the bulb is not pushed far enough back there will be a dark, round shadow in the middle of the bright light in the road ahead.

Good connections: There should be just as few wire connections as possible in wiring for electric lights or starting purposes. And these few should be made secure against rattling loose by soldering.

The "master vibrator." When a master vibrator is attached to a regular coil it not only serves to equalize the spark supply to all the cylinders, but it also adds extra condensing power to the current, giving a hotter spark.

To test the firing of the cylinders independently, the plug cables should not be held too far from plug, as this throws a severe strain on the insulation of the coil.

It always saves time in investigating for causes of misfiring to try the effect of a new set of plugs, because, in the majority of cases nowadays, any persistent misfiring is due to a spark-plug defect.

Sticking tires: Make the surfaces of rim smooth with emery cloth, apply graphite to the rim, and beads of the tire, and your tire will never stick.

To get out of deep mud: Wrap your tire chains bodily around the tire and rim of wheel so as to make a big bunch, fastening it on with strap or wire; turn on slow gear carefully; go slowly.

Over-sized tire chains: Tire chains intended for wheels larger than your own will, when cut down to fit in length, give you extra service and satisfaction.

Against skidding: A wise driver will straddle the ridge in the middle of a "greasy" road, or keep one wheel in a wheel rut, to prevent skidding.

Putting muddy chains away: Hang them to some convenient support, such as the bow rests at rear of car, and, with both hands, hold the bag open and slip it up over the chain.

A good place to carry chains: A shallow box fastened under the footboards of the tonneau, having several half-inch holes in the bottom, makes a good place for tire chains. Put them in with the mud on, and as it dries it will shake off the chains and through the holes.

Quick tire destruction: A good way to spoil a tire casing quickly is to start your car with a lunge, and stop it with a sudden application of the brakes.

Size of inner tubes: Some manufacturers of inner tubes economize in material by making the tube smaller than it should be for the casing which it is to fill. An inner tube should fill the casing without being distended more than a very little. I find that as a rule the so-called "over-size" tubes, such as 33x4 are best for use in casings 32x3½.

Why is a blow out? When outside wear or inside break in the fabric due to bruises produces a comparatively weak place in a casing, the inside pressure causes a bulge in the location of the weak spot, and this part is then exposed to more wear in travel than the sound parts of the casing. Of course the blow-out quickly follows. Strong inter-liners prevent this bulging, making a slight depression at the worn spot in place of a bulge, and thus preventing excessive wear on the weak portion of the casing.

Great tire mileage: The difference between the tire mileage of different drivers depends quite largely upon the care used to avoid sharp substances in the road. A small, sharp-cornered stone will often make a break in the fabric, and a broken beer bottle will sometimes cut a fearful gash. Tire wear also increases in a fourfold ratio compared with speed. Almost any old tire will run ten thousand miles if carefully favored.

Surprised at the bill: It is quite common for a patron to be surprised at the size of a repair bill, and to go away "sore." This causes him to shun the shop in the future, and also to tell his friends that the repairman in unfair. It would be better policy if an estimated price could be given for the work before taking the job.

The price to charge for work: When a shop is completely equipped with labor-saving tools and conveniences, the patron should pay seventy-five cents per hour for mechanical labor. When not so equipped, a large amount of time is wasted as a consequence, and the patron should not be asked to pay for wasted time.

Preserve the varnish: Ordinary mud, when allowed to dry on, will dim the luster of the best varnish. Rinse it off with a gentle flow before it becomes dry.

Stale gasoline: After standing for many days, even in a tight tank, gasoline will become dead and slow to ignite: It is partly due to evaporation, and partly to chemical changes that take place.

Fender cleaner: Equal parts of turpentine and wood alcohol make a good cleaning preparation for fenders and hoods.

Varnish in a common barn: The varnished surfaces of an automobile body will not remain lustrous very long if the car is kept in a barn where there is manure. The nitrogen compounds given off from manure will soon tarnish and destroy the best varnish.

A slouchy back curtain: A small stick of length equal to the width of the curtain, upon which the back curtain is snugly rolled, gives a neat appearance. Otherwise it will hang in baggy masses.

Putting in a back window: After cutting the celluloid to proper size and shape fasten it temporarily in place by pushing pins through at each corner. Then button the curtain taut, and with a second person on the inside to pass the needle through outwardly, sew it in place, using the original needle holes as far as possible.

A convenient receptacle: By cutting out a square in the floor of the tonneau and attaching a proper sized box underneath you can have a very convenient carrying receptacle in space that is not otherwise taken up. It makes a good place to put a carbon foot-warmer in winter, and may be used for tools and jack at other times.

Vibration and rattle: A soft leather washer placed between two iron washers will often serve to stop the rattle of fenders and brace rods.

Silence and easy riding: An occasional lubrication of the inter-leaf contact parts of the springs will quite materially increase easy-riding quality of a car, as well as eliminate noise.

Friction noises: Wherever two surfaces rub together making a squeaking noise, graphite grease makes the best remedy. Oil in such places is but a temporary makeshift.

Back lash: Non-reversible steering gears usually have a certain amount of back lash to allow the wheels to follow ruts without side resistance on the tires.

Keep radiator full: When the cooling fluid is kept in motion by thermo-syphon action it is quite important that the radiator be kept reasonably full in order that there be a back resistance to aid in forcing the water forward. It is good engine care to frequently add a little cold water, instead of waiting for the engine to knock for water, especially in summer.

To get a locked car home: When the drive wheels are locked from breakage in the differential or the universal joint you can haul the car home by removing the keys that hold the rear wheels to the axles (if a Ford) and allow them to turn freely. Be sure to grease them well.

That harsh, grating sound: When an amateur driver shifts his gear, the excess of sound makes an expert smile. **To shift gears noiselessly, release the clutch to its fullest extent,** then push the change gear lever with a quick jabby motion until the gears go in. Do not slowly push the lever into position. This causes the teeth of the gear wheels to strike and be thrown back, and each approach repeats the noise. The expert endeavors to secure co-ordinate speed of the gears before trying to throw them into mesh.

Water which comes from a chalky district should preferably not be used in the water-circulation system, because this results in deposits of lime forming in the pipe and radiator. Distilled water or well-filtered rain-water should be used.

A test for worn piston rings: When there is an escape back past the piston rings of hot gases the crank case will get warm. When the escape is past the valves this is not found.

To start engine if starting crank is lost or starter fails to work: Jack rear wheel, let clutch in place gears in "high" and turn the wheel. Or let clutch in and have some one push car until engine starts and quickly throw out clutch when engine starts.

A test for trueness: Upon examining crank shaft or connecting rod bearings if you find that they are worn a little more at the ends than in the middle, it means that the crank shaft is not quite true.

Tight bearings: When the removal of a shim makes the bearing too tight for free use, a piece of manilla paper in place of the shim will often give corect adjustment, and will permit a slight tightening if needed subsequently.

To loosen sticking wheel: When a wheel on a taper axle sticks, and you haven't any wheel puller, here is a way to loosen it: Run the nut off entirely, and then run it on again with the castellated end toward the wheel. True the other end of the nut up flush with the axle, letting the wheel down onto the ground from the jack. Hit the nut three or four good cracks with the hammer and the wheel will start every time.

Loose rear wheels: It is wise occasionally to examine the rear wheels for slack. A little wobble on the axle will soon wear the key or key-seat into a dangerous wheel condition.

Broken balls are first indicated by a "clicking" sound. If not promptly remedied entire bearing will be ruined.

Knocks are expensive: At the end of the first two thousand miles the average automobile will require slight tightening up of the crank shaft and connecting rod bearings. To allow small knocks to go uncared for will result in great damage to the parts very soon.

A good carbon remover: Denatured alcohol, squirted into the cylinders when they are hot, and the engine run fairly fast for two minutes, will clean out the carbon.

Adjust your foot brake: Push the pedal forward about two inches and retain it in place with a small block of wood. Now tighten up the turn-buckle until the brakes are snug, and when the block of wood is removed the slack will be correct.

Broken piston rings: Will make themselves known by decreased compression, and by an excessive amount of oil in the combustion chamber and on the spark plugs.

Use split washers: Where castellated nuts and cotter pins are not supplied in automobile construction, good, well-tempered lock washers may be placed under the nuts or the heads of bolts, to keep them from rattling loose.

Impulse air pump—don't run it fast, and don't connect the hose to tire valve, until pump has made a few strokes.

A small magnet is a time saver for picking up screw and other small parts that have dropped into the mud pan. Often the trouble of taking the pan off will be avoided. An ordinary horseshoe magnet, purchasable at any hardware store, may be used.

Where a pump is used to circulate the cooling water it is wise to fill the radiator to the top and then turn the engine over several times, so as to insure the water reaching and filling all parts of the system. If the engine is not turned the pump is an obstruction to the passage of the water into the jackets, which remain partly empty or fill so slowly as to leave the impression that there is more water in the system than there actually is.

In order to clean the inner lining of a top and to remove stains, gasoline should not be used. The best method is to lift the top off, and, after inverting, clean the surface thoroughly with pure soap and water. If gasoline or other quick-acting fluids are used the waterproof of the fabric will be destroyed.

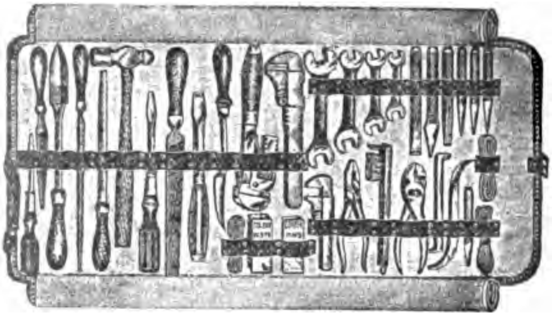
A disagreeable rattle can often be traced to the hood where it rests on its seat. Strips of rawhide or other anti-friction material should be installed to prevent any squeaks or rattle.

Although French chalk placed between a tube and the shoe is very desirable to prevent adhesion, too much of it may prove as bad or worse than none. If too much is used it is likely to work up into little balls, when the continual rubbing and rolling around will ruin a tube in short order and make it almost beyond repair scarcely worth the cost of the work.

To tune a car up for slow race or slow running on high: Probably the engine which runs the slowest and the car which is geared the lowest will be the winner. We will assume that the race will be only on the high gear. By retarding the spark this will also assist in reducing the speed of the engine, but if run too long with retarded spark, engine will heat. The timing of the valves could also be changed by setting the valves to open and close just a little late.

If one prefers to have his engine adjusted to run slow on high, to best advantage, the valves can be adjusted accordingly, but the speed will be sacrificed.

"Dont's" for drivers: Don't drive a car until you are old enough to have good ordinary "horse" sense. Don't look around when your hat blows off. Don't try to kiss the lady in the seat beside you. Don't go to sleep while driving. Don't trust one hand to do the guiding. Don't try to make up lost time by speeding down hill. Don't run at night without lamps. Don't delay putting on the chains when the roads get greasy. Don't forget to "STOP, LOOK and LISTEN" before crossing a railway track—Safety First, Last, and all the time.



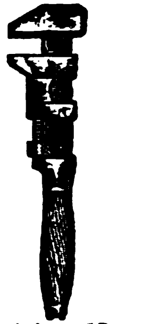
A Well Assorted Repair Kit.

6⅝-Inch Drop Forged Hardened Wrench.
5⅞-Inch Drop Forged Hardened Wrench.
4⅞-Inch Drop Forged Hardened Wrench.
4-Inch Drop Forged Hardened Wrench.
4½-Inch Warding File with handle.
8-Inch Square File with handle.
8-Inch Flat File with handle.
7-Inch Round File with handle.
5-Inch Square Shank Screwdriver, polished.
Machinists' All Steel Heavy Screwdriver.
½-Pound Soldering Iron with handle.
6-Inch Side Cutting Pliers.

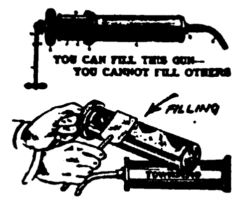
Spark Plug Brush.
⅜-Inch Cold Chisel.
Bundle Wire Solder.
Bundle No. 13 Copper Wire.
Bundle No. 20 Copper Wire.
5-Inch Bicycle Wrench, nickeled.

¼-Inch Cape Chisel.
⅜-Inch Solid Punch, 3-32-inch point.
⅜-Inch Solid Punch, 3-16-inch point.
⅜-Inch Solid Punch, ¼-inch point.
3-Inch Electricians' Screwdriver.

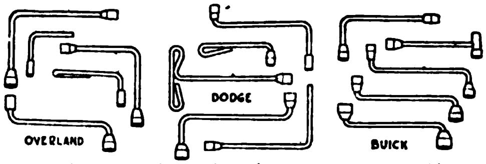
6-Inch Adjustable Combination Pliers, nickeled.
Machinists' Bearing Scraper.
9-Inch Auto Monkey Wrench.
10-Inch Stillson Wrench.
8-Ounce Machinists' Hammer.
⅜-Inch Cotter Pin Extractor, polished.
⅜-Inch Center Punch.
½-Inch Cold Chisel.
Box Solder Paste.
Box Cotter Pins.
6-Inch Offset Screwdriver.



A long 18 or 21 inch monkey wrench for removing valve caps, hub caps, etc.

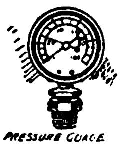


A good grease gun.

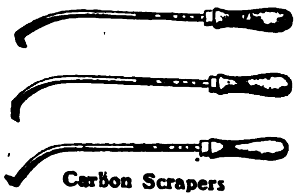


Walden socket wrenches come in sets for various cars and are accurately made to fit the nuts on each car

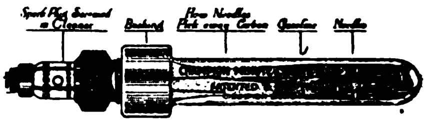
A flat type of blow pipe torch is handy to carry about.



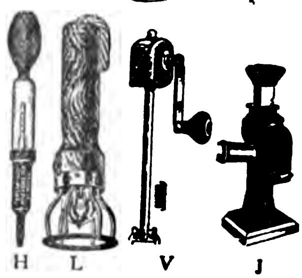
Oil Gun



Carbon Scrapers



Plug Cleaner: Fill ⅓ full gasoline; screw plug in glass tube and shake.



H—Hydrometer; L—electric test light; V—valve grinder. This one is made by the Marvel Accessories Co., Cleveland, Ohio. J—jack. A thickness gauge, per page 864L and 699, a very necessary article.

Electric testing instruments: pages 864H, 864I. Micrometers and thickness gages (p. 697, 699) are necessary.

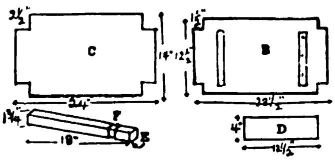


Fig. 20: A portabe tool stand. The illustration gives the dimensions. If you desire, the bins can be divided into smaller sections for cotter pins, washers, assorted bolts, nuts, etc.

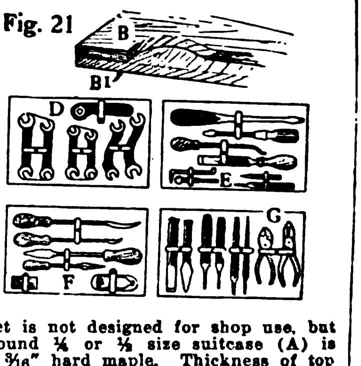
Fig. 21



A trouble-man's repair kit: This set is not designed for shop use, but for outside trouble calls. A leather bound ¼ or ½ size suitcase (A) is fitted with four wooden trays made of 3/16" hard maple. Thickness of top piece (B) depends upon size of tools. Outlines are drawn on the wood with pencil and wood cut entirely away to permit tools to lie flush. The bottom piece (B1) is then glued on and fastened by wire brads. Buttons holding tools in place are made of sheet brass. **General arrangement:** hammers strapped in cover C; wrenches in top tray D; screw drivers and punches in tray E; bearing scrapers, oil stone, Prussian blue tray F; chisels, files, pliers, tray G. (Motor World.)

CHART NO. 242—Suggestions For an Auto Mechanician's Outfit. How To Make a Repairman's Tool Kit. A Portable Tool Stand for Shop Use, Etc. See also page 614, 698, 699, 864H, I & J.

INSTRUCTION No. 44.

THE AUTOMOBILE REPAIRMAN: Starting into the Auto Repair Business. The Auto Mechanician. Parts to Overhaul on a Car and Engine. Prices Usually Charged for Repair Work. Tools for the Auto Mechanician.

Starting in the Repair Business.

The auto repairman must know how to adjust any part of the car. To know how to adjust, he must first know the principle of the construction of the parts as explained in previous Instructions, and must know when and where to look for trouble. (See digest of troubles; Instruction No. 43.)

About one-half of the work of the automobile repairman is in making adjustments and fitting parts; such as carburetor adjustments, cleaning carbon, grinding valves, fitting horns, muffler cut outs, diagnosing troubles and numerous other little details, which does not require a machine shop, but does require a good assortment of tools, and a knowledge of the principle of the construction of a car.

A machine shop is not necessary, unless there is sufficient work to keep more than one machinist busy. A great number of small repair shops put in only the tools needed for the average repair work, and when they have a job of machine work to do, they take it to a machine shop. In other words, a machinist and an auto repairman follow two different trades. The auto repairman need not be a machinist; I mean by machinist, one who can turn all kinds of metal parts on a lathe and do actual machine work. Therefore, we will explain only the work the average auto repairman is called upon to do.

A Few Pointers for the Beginner.

When beginning work on a car or engine, remember system and order are two things every repairman ought to learn early, they mean success.

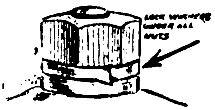
Don't throw nuts or bolts on the floor. Place them in a box or pan.

There is nothing more disgusting to a man who owns a car, than to walk into a repair shop and find a careless workman dumping nuts, bolts, etc., here and there on the floor. That customer will say to himself; if that workman is as careless as that, he is careless enough to leave a nut in my crank case and ruin my engine when it is started up, or he will leave off lock nuts or lock washers and cause me expense and damage.

A little piece of metal, such as a piece of a cotter pin or the like, accidentally dropped into a can of grease or oil and subsequently put into the gear case of a motor car has been known to cause much damage, and give the driver or owner of the car considerable trouble and expense.

A Careful Workman the One in Demand.

If you do your work thoroughly and carefully and always do a little more than you agree to do, you will be sure to make a success.



Before turning car over to customer be sure that all nuts have lock washers and are tight.

It's the careful man the auto owner wants to handle his car; not the fellow he can't depend upon. I will give you an example of a careless young man who lost his job. An auto owner had a young man overhauling his car; he told him to fill all the grease cups and be sure and see if the valve under the gasoline tank was tight; he had an idea it was leaking. He went away and when he came back that afternoon he asked the young man if he had attended to the different things he told him to do; he said yes. Next day the auto owner was out on a country road and ran out of gasoline. He found that the young man had not examined the valve carefully and the leak had exhausted the tank—the valve was in a difficult place to get at under the car, so he simply took it for granted that it was all-right and let it go at that; so you see a careless man is worse than none at all—it's the dependable fellow who will win.

Don't Overcharge.

We want to warn you that in the matter of charges, it pays to be liberal. Automobile repairmen like plumbers, generally have a reputation for exorbitant charges. Make it a rule to do a little more than you agree to. It is well to comment on your work in talking with the auto owner, like this: "I noticed that some of the nuts were loose around the springs, so I went over all the nuts on the running gear and found that many needed attention. You want to watch those little things, and then you won't need me so often." The owner may not say anything out loud but he will certainly comment to himself, "there's a good repairman," and that is the most profitable reputation you can establish.

You are building a business for the future when you do your work right and treat your customers fair.

*The Repair subject has peen divided into several instructions. A study of the headings of Instructions 44, 45 and 46 A, B, C and D will give the subjects treated.

The Automobile Repairman and Mechanician.

We will classify the automobile repair work into two classes: first, will be the automobile repairman who works in a shop under a foreman. His work is laid out for him and he is advised just what to do.

The second, is the automobile mechanician whom we will class as an expert; he will generally be found in the position of a foreman, or operating his own shop. We also find him doing work at the homes of automobile owners.

For the sake of classification and names to distinguish this latter class of work, suppose we call the "auto mechanician" the one who makes a specialty of doing work at the home of automobile owners, in the auto owners private garage.

The Auto Mechanician—how to start.

Many men have found this work profitable and it has been the stepping stone for a future. This work also applies to marine engine and stationary gasoline engine work.

In order to successfully engage in this work, it is necessary for him to provide himself with the necessary tools to do the average work around a car.

I dare say that nine cars out of ten need greasing; that is, the gears, differential, wheels and universal joints. This job is one that does not appeal to the auto owner and the chances are he is not prepared to grease his car if he wanted to. It's easy enough to put grease in the compression cups and screw them down, but to grease the rear axle parts and universal joints, that is a different job unless he is supplied with the proper tool. The auto repairman with the Townsend grease gun, as shown in chart 242, can do the job quickly and easily.

Then there are the valves to grind, carbon to clean out, lost motion in the valves to take up, compression to test—in fact, a general engine overhaul or a general car overhaul would constitute the work that the auto mechanician could do on these special jobs.

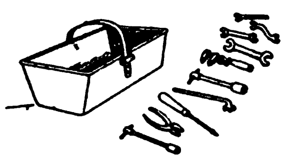
We have illustrated in chart 242 a good equipment for the auto mechanician who proposes to do this class of work.

Very likely when the auto mechanician goes to an auto owner's home to do repair work he will be provided with most material, such as oil, grease, waste, etc., but it is advisable to suggest a good oil and request that the car be supplied with it, providing the oil in use causes a great deal of carbon. In other words, it will be necessary for the mechanician to be able to diagnose all troubles and suggest their remedy, as well as make adjustment and overhaul the car.

Auto Mechanician's Outfit.

Is shown in chart 242, which is suitable for general work around a car, testing etc.

The average workman carries more tools than are necessary to the job, and often finds that even then he does not have the right one. A careful study of the cars handled usually shows that 12 of the common tools will serve to do the ordinary job. It has been found that the following tools are most essential, and are adequate for most jobs: Four open end wrenches, Nos. 34, 25, 29, 734; 1 monkey wrench; 1 main bearing wrench; 1 connecting rod wrench; 1 screw driver; 1 pair pliers; 1 valve cap wrench.



Keep your tools in a box or kit.

Don'ts For The Repairman.

1—Lay wrenches, hammers, chisels, etc., on the fenders or on the seat cushions. Cover the fenders, and remove the cushions during the work.

2—Spill oil, or smear grease over the finish or upholstery.

3—Try to squeeze one car past another in the shop, even though the fenders will spring enough to let the car pass.

4—Pound the end of a shaft with a bare hammer. Use a babbitt hammer, or deaden the blow with a piece of brass or wood.

5—Push a car around the shop, with greasy hands on the varnished surfaces. Either wipe your hands or place a piece of dry waste between your hands and the car.

6—Leave a car standing in a pool of grease.

8—Use an 18-in. Stillson on a ⅜-inch nut.

9—Sit on the cushions with your greasy overalls. Spread a newspaper over them first, and don't put your greasy hands on doors, body, hood, etc.

10—Use his gasoline just because its handier than to get some from store room.

*A Car Overhaul.

The following enumerated list gives a detail of procedure in giving a car a general overhauling. Where the automobile owner keeps his car at home and cares for it himself, nine chances out of ten his car and engine needs cleaning, greasing, valves ground, or carbon removed. All of the work mentioned below can be done in the auto owners private garage. This work then would require but a few well selected tools and chances are the auto owner would have most of them. Supplies such as oil, waste, etc. would be furnished by the auto owner. This class of work is well suited for the beginner or auto mechanician.

Cleaning Engine.

1—Clean engine outside with gasoline (see index "Cleaning Engine.")
2—Clean engine inside with kerosene.
3—Clean drip pan.
4—Clean and pack pumps.
5—Clean and adjust spark plugs.
6—Clean the gasoline strainer.

*See also pages 620, 794, 795. *See page 527, "Testing a Second Hand Car"—this is a good test to give a car before overhauling in order to determine its exact condition. A record should be made of each test.

Lubricating Engine.

7—Put fresh oil into engine after cleaning (see instruction 46).
8—Oil other parts of engine, as magneto, starter, generator, fan, etc.
9—Screw down on all grease cups and refill.

Cleaning Car.

10—Wash car (see page 507.)
11—Polish body with body polish (see page 508).
12—Clean clutch.
13—Clean transmission and underneath car.
14—Clean steering device.

****Lubricating Car.**

15—Screw down all grease cups and refill.
16—Grease clutch shaft.
17—Grease universal joints.
18—Fill transmission with lubricants.
19—Fill differential housing.
20—Grease steering device.
21—Grease front wheels.
22—Lubricate the springs.

Inspection and Adjustment.

23—Inspect all nuts and tighten.
24—Inspect gasoline line and tighten all joints.
25—Inspect the balls of front wheels when greasing to see if there are any broken balls. Jack wheel and listen for a clicking sound.
26—Inspect and tighten all loose water connections.
27—Inspect the tires and see if properly inflated.
28—Inspect the steering device and connections and tighten and grease.
29—Inspect the springs and fenders and nuts, tighten and remove squeaks.
30—Inspect rear wheels, see if loose, if so draw up on the nut.
31—Inspect the differential, if noisy, take up lost motion.
32—Examine brakes, if loose adjust them, also tighten spring bolts, nuts and spring clips.

Inspection of Engine and Parts.

33—Inspect water hose on engine and replace with new hose if required.
34—Inspect gaskets on engine and draw up on cylinder head.
35—Inspect bolts and nuts holding cylinder to crank case and tighten.
36—Inspect all nuts and tighten on crank case.
37—Inspect generator adjustment and draw up nuts.
38—Inspect the nuts holding exhaust and inlet manifold and tighten.
39—Inspect for air leaks at carburetor, manifolds, spark plugs. If a leak engine will not idle properly.
40—Inspect all nuts and cotter pins and tighten.
41—See that lock washers are under all nuts.
42—Inspect the muffler and clean if necessary and tighten up.
43—Inspect the timer or magneto and see if connections thereto are tight.
44—Inspect horn, magneto, switch, generator, starter and battery and coil connections, see if there are any loose binding posts or connections. Don't forget to tighten all ground connections.
45—Inspect battery, see if all terminals are tight.
46—Inspect and test the storage battery with a hydrometer (chart 204), also "cadmium test," page 864D.
47—Inspect starting motor and generator to see if there are loose connections.

***Engine Adjusting.**

48—Test compression.
49—Clean carbon from cylinders.
50—Grind valves.
51—Adjust valve clearance.
52—Test for weak exhaust springs.
53—Test engine for knocks.
54—Take up on any loose bearings.
55—Fit piston rings if necessary.
56—Check up the valve timing (see page 110).
57—Clean and adjust spark plug gap.†

Prices Usually Charged for Car Overhaul.

The price usually charged is from 50 to 75c per hour. Quite a number make a flat price, for instance, after handling a few jobs, the work would come easier and systematic and you could then make a flat price of say $25 for overhauling and cleaning a Ford. (see Ford Instruction.)

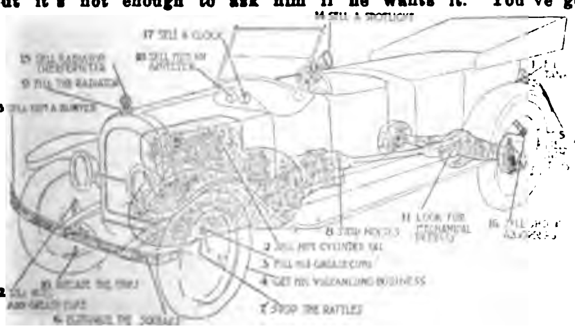
To give an idea for charges where you must make a flat price and where only certain parts of the list are used we give the following scale.

Carbon removed, per cylinder......50c to	$ 1.00
Cleaning and adjusting spark plugs......	.75
Oiling and greasing car	1.50
Cleaning car and polishing..............	1.50
Cleaning engine and drip pan...........	.75
Tightening loose nuts and cotter pins.....	.75
Tightening water and gasoline line.......	.40
Adjusting carburetor and valve tappets and tuning up engine	2.00
Grinding valves ....5 to	10.00

Sell Supplies.

When the motorist drives up to your garage for gas or oil, or air for his tires, give his car the quick once-over and see if you can't sell him some accessories. Here are the places you should look: First fill his tank, then ask if he wants oil, then fill his grease cups, and so on. After you have done one thing, turn to the next.

When a motorist asks for an accessory, this should suggest something else that you can sell him. But it's not enough to ask him if he wants it. You've got to tell him why he ought to have it. That's what these selling arguments are for. Use them!



This illustration gives a brief list of merchandise or auto supplies, etc., which the garage dealer ought to sell to his customers. The illustration is taken from Motor World which is intended to be kept in front of the dealer in order that he memorize the list.

Most sales of accessories are lost for the want of a word. Every car owner needs something, and a quick glance over the car—thorough and systematic—will reveal what it is.

**See below for usual charges, and page 574 for charges for tire repair work. **See page 204 for example of greasng a car, also page 203, 205. †See page 542. *Explained in Instruction 46. See also, page 528.

Fig. 1.—Garage.

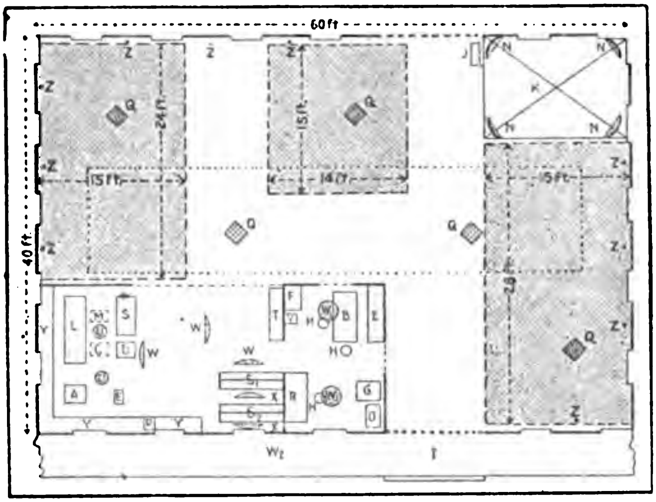


Fig. 1—Floor plan of the garage, showing location of departments, skylight and arrangement of tools and lamps

This garage is designed with a view to economy.

This garage is a one story brick building, 60 by 40 feet, with the longer side toward the street; the interior height is 14 feet from floor to roof, and the latter is carried on trusses 40 feet long and spaced 8 feet apart.

A skylight 10 feet wide and 50 feet long with windows illuminates the garage during daytime.

Near the middle of the street side (1), 15 feet from one end, is located the main door, which is 10 feet wide. Entering through this door a row of four automobiles is arranged at the right, while at the left is the entrance to the garage office. Adjacent to the office door a board 3 by 3 feet is hung on the wall, on which checking forms, which constitute a part of the garage system, are kept.

The office is 10 feet wide and 15 feet deep, and besides the entrance mentioned, has one door leading into the repair shop and another into the garage proper, which has a floor space of 1275 square feet.

The space filled by automobiles is shown by shading, and there is enough room to accommodate nine cars of 124 inches wheel base and standard tread. The space between the dotted portions illustrate the passageway for automobiles driving to or from their assigned positions in the garage. From the garage proper a 10-foot door leads into the back yard, and adjacent to this door the washrack and charging outfit are located.

The **wash-rack** is formed by a rectangle deepening toward its center, whence a pipe for the flushing water leads to the sewer, or other drainage system. The water is supplied either through the medium of ready-made car washer, or through one which can be readily made from ¾-inch standard pipe, a stuffing box, four elbows and about 13 feet of ¾-inch water hose, at a cost of less than $8. The method of assembling the parts is shown in fig. 5, chart 246.

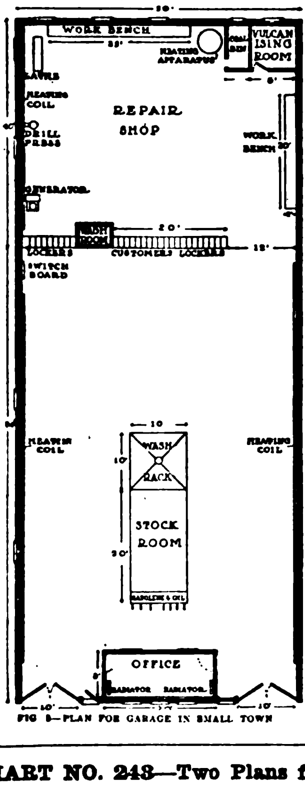

FIG 8—PLAN FOR GARAGE IN SMALL TOWN

The repair shop in this small 9 car capacity garage is but 24 feet long and 15 feet deep, and, besides the door connecting it with the office, has a sliding door between it and the garage proper. This door is sufficiently wide to permit of an automobile being passed through it into the shop, which also contains a small stock of raw material and repair parts stored in shelves S1 and S2, and a tool shelf T.

Fig. 8.—Garage.

Another arrangement and equipment of a garage and repair shop suitable for a town of 3,000 population with good transient and country trade. The size of the building to be 50 by 120 feet, one-story brick or cement block, with the repair shop 40 by 50 feet at the rear.

Fig. 8 shows a garage which would suit the requirements stated beside being convenient and cheaply maintained. It allows of cars entering at one side and leaving at the other, thus avoiding any congestion in getting in and out. Gasoline and oil are handy to the street, besides being under the direct scrutiny of the office.

Posts should be barred and the roof supported by trusses, making the working space much more valuable and saving many accidents to lamps, fenders and varnish. Heat is supplied by a hot-water apparatus located in the repair shop. It is of the overhead supply type—that is, the supply veins extend from the boiler at the ceiling height and branches drop down to the coils and radiators and return just above or under the floor. Steam could be used, but the boiler would have to be sunk considerably in a pit before this could be used at all successfully.

A small gasoline-electric generator set with suitable switchboard is suggested for electric charging and running the lathe and drill-press in case the local service is not direct current. Sky or other kinds of roof lights are a necessity if the garage is on an inside lot and are desirable in any case to make things cheerful and airy and attractive to transients who use it.

Average space to allow for storage of cars; 7 feet is the usual width. The length varies from 13 to 18 feet according to length of cars stored.

CHART NO. 243—Two Plans for a Garage for a Small Town: 60x40 feet and 50x120 feet.
(Motor Age.)

INSTRUCTION No. 45.

BUILDING AND EQUIPMENT OF GARAGE AND SHOP and Approximate Cost. Layout for a Small Garage and Repair Shop. Heating and Lighting a Garage. Tools, Machinery, Money-Making Additions. Appliances and Useful Devices. How to Build a Home Garage. S. A. E. and U. S. S. Wrench Sizes.

Many, after starting in a small way, by doing work at homes of automobile owners, soon earn enough to start up a shop of their own. We will now lay out a procedure for starting a shop or garage.

A garage is a place where cars are stored and cared for. Most garages also have shops in connection.

If only a shop for repairing automobiles is planned, then figure enough room to take care of at least four or five cars while working on them.

A repair shop without the garage is profitable and can be started for much less capital. If the repair man is just starting out and his capital is limited the best plan is of course to start in a small way.

The best time of the year for opening a public garage or repair shop, is in February or March. At that time owners are getting their cars out of dead storage, are buying new machines, or if they are dissatisfied with the place in which they are storing their cars, they are prepared to make a change. It doesn't make much difference as to the size of the city.

The question to decide is the one of whether you intend to do strictly repair work or store cars and repair, also conduct an agency for some car and carry supplies.

Garage.

A garage is termed a place for storing cars, but is sub-divided into departments; storing, salesroom, auto supply department, and repair shop.

The garage equipment consists of suitable space for the number of cars you intend to store, bearing in mind that the space devoted thereto should be utilized to the best advantage, for instance, cars which are used frequently and regularly should occupy that space where exit is easy, usually nearest the exit. The wash-rack should be in convenient location and garage supplies, such as oil, and gasoline should be where convenient, yet not interfere with the space occupied by the cars.

The salesroom, office, and stock room should all be carefully planned. The stock room quite often is utilized for small tools and accessories, but it is better to display the accessories in some sort of showcase or shelves in a space in the salesroom.

Repair Shop.

The repair shop can be subdivided into departments as follows: machine shop, tire repair, welding room, electrical apparatus and testing department. The testing department should be a space allotted for the purpose of diagnosing the troubles, before actual work is begun.

The electrical repairs constitute re-charging batteries, work on the electrical apparatus, etc.

By maintaining a system of departments in this manner, the parts belonging thereto are easily located, work turned out quicker and a higher degree of efficiency maintained.

An extensive line of repair work can be carried on in even a small garage, and the sale of extras and sundries will add materially to the income.

Garage and Shop Buildings.

Successful garage operation is largely a question of systematic economy. This holds true for smaller garages even more than large ones, and therefore such an establishment requires great care in its layout, construction and subsequent operation. The more thought concentrated upon the system to be followed, once the building and equipment are ready for starting business, the fewer mistakes will be made and the greater will be the profit derived from the undertaking.

A Nine Car Garage and Shop.

The type of a small country garage as described in chart 243 is designed for the storage and general care of nine automobiles. Besides the space necessary for garage work the building contains a well-equipped repair shop and an office which also serves as a reception room.

In the repair shop a limited supply of parts and supplies is kept, the latter being provided for the accommodation of the garage patrons. The supply stock consists of the most important accessories, tires, tubes and ignition sundries, etc.

A Fifteen Car Garage.

Including salesroom, accessory store and shop, is shown in chart 248-A, fig. 1 and 2.

See page 616 for lay out for a Service Station and page 472 for Electric Equipment.

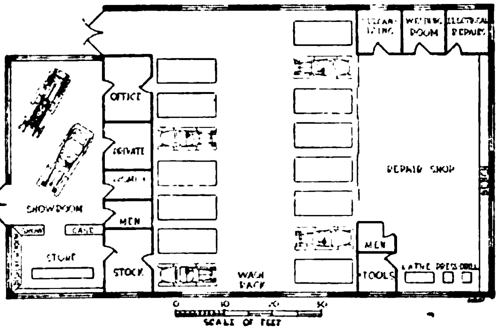

Fig. 1.—Plan view. The cars in front, near the shop doors should be the ones which are away from the garage the most.

Fig. 2.—Front view. Note the drive way to garage, gives the show room a corner appearance and light.

A 60x100 Garage Building.

Figs. 1 and 2: A one story building for a garage, salesroom, accessory store and shop—The scale drawing is shown in illustration to the left. The size of the lot is 60x100 feet. The building is erected so that another story can be added.

The entrance to the garage is exposed so that light can be obtained from two sides into showroom. Thus, you have practically all the advantages of being on a corner.

There is a small accessory store divided off from the showroom by showcases and an arch, a stockroom, private and general offices, rooms for men and women, garage space for fifteen cars, washrack, a shop big enough for five or more cars, and equipped with vulcanising, welding and electrical rooms.

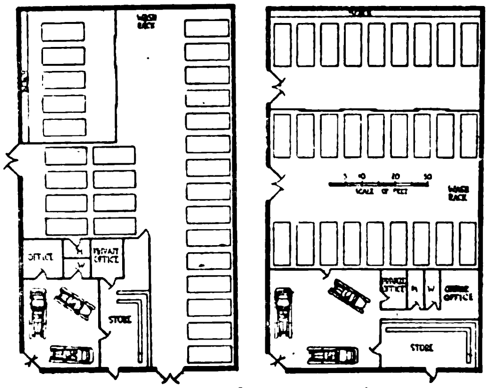

Fig. 3.—Left—complete establishment located on corner and with front entrance. Fig. 4.—Right—same with no front entrance.

A 66x112 Garage Building.

Figs. 3 and 4: A one story corner building for garage, salesroom, accessory store, offices, toilets, garage and shop. Size of the plot is 66x112.

There are two designs: fig. 4 is probably the preferable one considering all the conditions, but fig. 3 is the one to use in case a front entrance to the garage is considered essential.

The objection to the front entrance is that it restricts the frontage so that the display space for showroom and accessory store is rather small, but with the entrance on the side full advantage of the front may be taken and inasmuch as it may be considered as valuable advertising space it is essential to use all of it for display purposes. The question to decide is whether the advantage of having the whole front for display more than offset the disadvantage of having the entrance to the garage on the side street. Even if the garage trade is the most important part of your business, and evidently it is not, the side entrance is not very objectionable provided there is a large sign at the front stating that the garage entrance is on the side street.

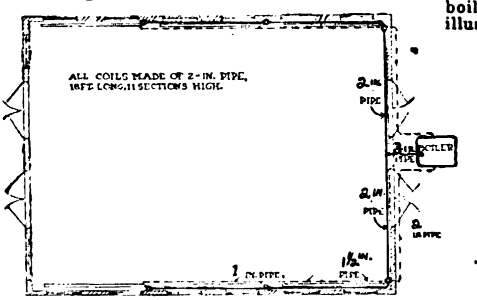
Fig. 3 has capacity for only five cars in the repair shop. Entrance to the garage is from both streets, but when the demand for space is strong, the last cars in at night may be placed in the side entrance way.

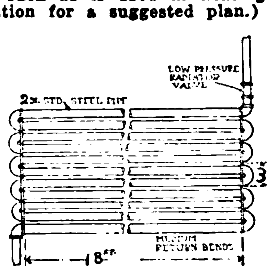
Fig. 4, which has no front entrance for cars, is not only a more attractive building to look at but also the layout of garage and repair shop is more convenient.

As far as storage capacity is concerned there is little to choose, fig. 3 having room for twenty-eight cars, including five in the shop, and fig. 4 having space for one less, including nine in the shop. The shop in fig. 3 may readily be enlarged if desired, by lengthening it.

Steam Heating a Garage.

As an example we will give the dimensions for garage 48x62: It is assumed that it is a steam heating system working at a pressure of 5 lb. gauge and you will use an ordinary low-pressure steam boiler, such as is used in heating houses. (See fig. 2 this illustration for a suggested plan.)





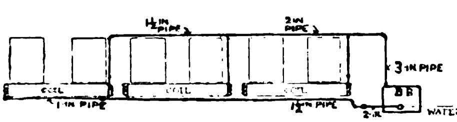


Fig. 2—Steam heating system for garage 48 x 62 The heating coils are made of steel pipe 2 in. in diameter

If you intend to place the boiler outside of the garage, you do not want to overlook the fact that it should be suitably housed, so that no heat will be wasted in warming the open atmosphere.

The boiler must be set so that the water line will be below the level of the lowest radiator or coil, so that the condensation will drain from the coils back to the boiler by gravity. If this is not done, the heating system will be very inefficient, as you will have to heat cold water up to the steaming point, instead of being able to reclaim some of the heated water.

CHART NO. 248A—Suggested Lay-out for Two, One-Story Garage Buildings. Steam Heating Coils.

(From Motor World, by Harold F. Blanchard.)

A Twenty-Eight Car Garage.

Including salesroom, accessory store, office, toilets and shop is shown in chart 243-A, fig. 3 and 4.

Heating a Garage.

The usual plan is by steam, or hot water. The method of assembling the pipes or coils is illustrated in chart 243-A. For garages of larger capacity there would be more coils and a larger boiler.

Lighting A Garage.

Fig. 5, chart 243-B, illustrates types of lamps, reflectors, and the placing of same to advantage.

Pointers on Office Work.

While it is very important to operate the office in a systematic manner, about seven out of ten neglect this part of the business. In chart 243-B, a system of repair checking cards and how to use them is fully explained.

The office, (fig. 1, chart 243) which is also equipped as a reception room; contains, in addition, a desk, table, chairs, safe and couch. The office is lighted by two 40-watt Mazda lamps with 12-inch diffusers. The price of the office furniture and safe is about $100.

The system designed to take care of all the business of this garage is exceedingly simple. To carry it out, only three forms are required; a monthly **checking sheet,** a monthly **supply sales sheet** and a **repair card.** In addition to these forms an ordinary ledger is used, in which each customer is given a page on which all his charges and credits are entered. (See chart 243-B.)

*Garage and Repair Shop Prices for Storage and Repairs.

The prices below are not standard but are about as near standard as can be compiled. Note the difference in prices to those who purchase gas, oil and grease from the company and who are regular customers and transients.

Per Month—(Regular Customer).

Roadsters, small, list under $1,400	$15.00
Roadsters, large, list over 1,400	20.00
Tour. cars, small, list under 1,400	17.50
Tour. cars, 5-pass., list over 1,400	20.00
Tour. cars, 7-pass., list over 1,400	25.00
Coupes and enclosed cars	25.00
Limousine	30.00
Electric—(Regular).	
Runabouts	$30.00
Coupes, victorias, etc	35.00
Cars with Edison equipment extra	5.00
Transient.	
Wash, polish and storage, first night	$2.00
Wash, polish and storage, each additional night	1.50
Storage only, per night	1.00
Dead Storage.	
One-third regular rate	Per month
Separate body storage, per month	$5.00

Repairs Per Hour.

Day labor, according to work	per hour	$0.60
Night work and outside work	per hour	.90
Sunday and holiday labor	per hour	1.20
Shop room for chauffeurs when owners furnish tools	per day	1.00
Chauffeurs furnished to drive owner's car (day)	per hour	.60
Chauffeurs furnished to drive owner's cars (night)	per hour	.60

We will not be responsible for cars left for repairs or storage in case of fire, water, cyclone or other accidents, or if car is damaged in delivery to and from our garage.

We are not responsible for articles left in cars or in the shop.

Note—the above is printed on a heavy card, 14x24 inches, framed and placed in a conspicuous place.

**Fixtures for a Garage and Shop.

Fixtures for the repair shop should consist of such things as: Shelves and racks for tools, such as stocks, hack saws, etc., should be on the walls at the back of the vise. A set of stout drawers for keeping bolts and screws and brass rods should be provided. Some of the drawers should be fitted with locks and keys, for sometimes tools will disappear. Several shelves should be put up for storing various spare parts, mandrills, etc., but it must be remembered that the shelves when full may have to carry a very considerable weight; they should be stout and well secured.

Fixtures for the garage would also consist of such parts as lubricating oil tanks, gasoline tank, wash hose and washing rack, heating plant, turntable, stock room, etc.

A heating plant, either hot water or steam with coil pipes or radiators must be provided. This plant should be in a cellar or on the outside of the building in a small brick enclosure.

A turntable is very handy for garages and should be placed in the center of the garage.

Next, fit up a wash rack as explained in chart 246. For the lubricating oils, a small enclosure can be provided made of wire fencing with a lock and key. A stock room is next in importance, as explained on page 601.

The gasoline supply should be stored in an underground tank, placed some distance from the building, from which it is piped to a pump located inside of the building near the wash rack. The gasoline tank should have from 120 to 280 gallon capacity. (See chart 244.)

A gasoline pump can be connected to a tank under the sidewalk or in the rear.

A Western gasoline pump, with the stroke adjustable for 1-4, 1-2, 1 and 2 gallons, and equipped with a 280 gallon tank, is

*See page 574 for standard price charged for Tire Repairing.

**See Instruction 46D, for useful home made devices for the Shop.

Lighting the Garage.

Fig. 5.—Three types of reflectors for lighting garage: Holophane type D'Olier steel type; 12inch diffuser; Intense type D'Olier.

Fig. 5.—Lighting the garage—(applies to fig. 1, chart 243), but can be applied to other garages of larger size by adding additional lights.

Naturally the repair shop requires even more elaborate lighting facilities than the garage space. It is therefore equipped with five 60-watt lamps and two 25-watt lamps, all of which are of the Mazda (tungsten type.) Three 60-watt bulbs W, fitted with Holophane D'Olier steel reflectors, fig. 5, and dropped from the ceiling to illuminate any part of the car being worked on, while two 25-watt lamps (W1) (shown in the shaded circles fig. 1, chart 243), are fitted with the same sort of reflector and are so located as to be useful in seeking parts stored on the stock shelves (S1).

Two 60-watt lamps (U) with Holophane intensive glass reflectors are dropped above the lathe, planer, and drill press, to shed a concentrated light on the work.

Artificial illumination of the garage proper is supplied by five 100-watt Mazda lamps, equipped with 12-inch steel diffusers with white enamel finish, fig. 5.

Special lighting provision is made for washing the cars; there are four 25-watt Mazda lamps located at the corners of the washrack, and these lamps are held in Holophane D'Olier steel reflectors, directing the light to the lower part of the automobile being washed.

See also page 465—how lights can be utilized for battery charging also.

Checking Sheet, Sales Sheet and Repair Sheet.

As referred to on page 599. The office work can be greatly lessened by using this system.

The checking sheet, fig. 2, is 3 feet high by 11 inches wide, with nine 1-inch-wide columns, allowing sufficient space for checking one car in and out every day of the month. Thirty-one horizontal lines are ruled one inch apart and the dates are printed under the heading "Date." Thus one square inch of space is provided for car "out" and "in." The checking times are entered by the day workman, who spends his time keeping garage and cars in shape. After the end of the month the sheet is filed for future reference.

4—30	8	Havoline	1 gal.

Fig. 3.

Fig. 2.—Monthly checking sheet for cars housed in garage.

Fig. 3.—Monthly supply-sales sheet kept with checking sheet.

Gasoline, oil and other supplies bought by garage patrons are noted on the supply-sales sheet, fig. 3. If this sheet is made as large as the checking sheet it will last a full month. On the last day of the month the sheet is taken off its board, the sales are entered on the car owner's pages in the ledger and the stock records corrected in accordance with the sales record. Then the monthly bills are sent to the patrons. Where materials of any kind are sold to any but regular patrons, the price and the notation "paid" is entered on the sales sheet instead of the number of the car.

For the handling of repairs the repair card, fig. 4, is designed. These cards are used in series and are numbered consecutively. They consist of three portions with perforations between. The middle portion is filled out when a car is brought in to be repaired, the name of the owner, number of car and date of the order being written on the blank. Then follow the specifications of the work to be done. The card is then attached to the automobile and accompanies it to the repair shop.

The upper portion of the card is now used as a time card, the name of the workman and his starting and stopping times being entered upon it. As the work progresses the man checks every item of the work, and finally enters his total working time on the card. If it be necessary to draw upon the repair parts stock or buy material from outside, the lower portion of the repair card is used as a requisition, upon which the needed material is entered. If it is not in stock, and has to be bought, an order is made out after the requisition. In every case the cost of the repair part is entered on the requisition, which is O. K.'d by the owner before an order is sent out. The repair work being completed, a charge covering time and materials of the repair is made out from the parts of the repair card and entered on the ledger page of the car owner. Thus when the monthly bill is made out all charges against a patron come up at once.

When the repair card is no longer needed it is filed away under its number, the file being kept, with the ledger, in the safe of the office. This makes a very compact system, all parts of which are accessible to the owner of the garage at a minute's notice, thus enabling him to keep his operations on a high plane of efficiency.

Fig. 4.—Practical repair card, combining repair order, material requisition and time card of work-

sold by the maker for about $200. A curb gasoline outfit is shown in fig. 10 chart 244.

Lubricating oils should be carried in about three grades: Light, medium and heavy gas engine cylinder oil, also gear case oil and greases. (see chart 244.) Sixty gallon tanks are usually provided for lubricating oils, and all are placed near the gasoline pump.

A lubricating oil tank and a pump capable of delivering anything up to the consistency of transmission grease, are made by concerns mentioned at bottom page 602. The entire gasoline and oil outfit would cost about $250. Smaller and cheaper lubricating tanks can be had as per charts 244 and 244-A.

Many useful devices, in the way of time saving additions are shown in charts 245, 246 and 247, also see air compressors, charts 237-A and 237-B.

A forge is indispensable; if it burns coal, it should be under a separate roof. Gas is used quite extensively, however, for this purpose and may be placed in the shop. A good portable blacksmith outfit is shown on page 616.

An inspection pit is useful, placed at any convenient place where the auto can be run over it. The pit permits the repairman to get under the car and work and should be installed. (See charts 244-A and 245.) The writer's pit is 6 feet long, 2 feet 9 inches wide and 2 feet 9 inches deep. A mirror is very handy for throwing the light in dark corners when at work in the pit under the car.

A chain hoist, for lifting the engine and other heavy parts, will pay for itself many times over in time and labor. (see page 616.)

Fire extinguishers should be kept handy. The only part of the building, (if made of concrete or brick), that is liable to fire is the roof. In case of fire—keep two or three buckets of sand handy (or fire extinguishers) to put out gasoline fire, as water is useless.

A water connection in the repair shop will be handy and should be installed.

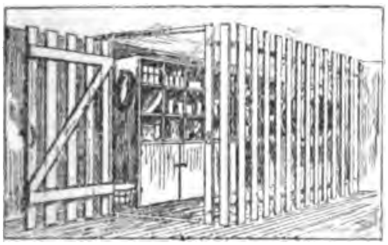
Electric lamps with wire guards and a long cord for working around the car is very necessary.

There is no end to the number of useful devices which can be installed in a repair shop and garage. We have selected those which are most necessary and will now suggest other desirable devices for use around a shop. (See charts 245 to 247 and Instructions 46 to 46-D.)

The Stock Room.

More money is lost in the repair shop and garage by having supplies scattered over the shop promiscuously, than in any other part of the business.

Every repair shop no matter how small should provide a stock room with a good lock and key and everything in the way of supplies kept therein.



See charts 247-A, 247-B, for list of supplies.

Systematic arrangement and a place for everything and everything in its place will save time and money.

The stock room is generally placed in some convenient place in the garage or repair shop. It is usually constructed of lattice work with good Yale lock on the door. In large shops the stock room is in charge of a responsible person, whose business it is to keep the stock replenished and deliver material to the workmen and customers.

Supplies in the rubber line. Repair shops can make extra money by carrying rubber supplies which are generally made by tire concerns, such as automobile spring bumpers, rubber horn bulbs, collapsible rubber buckets, etc.

Automobile rubber mats which comes in rolls 3-32 to 1/8 inch thick and 35 to 48 inches wide Matting also comes corrugated and perforated.

Radiator hose, tire tape. Rubber tubing for gas; tire inflating tubing; comes in black, white or red. Sizes 1/8, 5/32, 3/16 and 1/4 inch inside diameter.

**Money Making Additions.

There are several extra additions which can be added, all necessary and well worth the investment.

Tire department; a small or large vulcanizer for repairing tires, see fig. 2, page 610.

A battery charging department; for recharging, starting, lighting and ignition batteries, see fig. 1, page 610, 460 and 462.

During the winter months, there is much more of such battery recharging work brought to the garages because the cold weather reduces the charge-holding capacity of the storage batteries, while at the same time the cold engines require more current from the batteries to start them.

Oxy-acetylene outfit for welding and carbon cleaning, pages 610 and 727. Of course, with all this more room will be necessary, but it is surprising how small a space all the above can be carried on in, if properly planned out.

There is quite a profit in handling lubricating oils, grease and gasoline, and, if possible, an equipment for handling same should be added.

The car rental service is something worth considering and can be added in time.

A supply department is very remunerative, providing the proper supplies are carried.

*See Instruction 46-D for useful Home-made Devices for the Shop.
**See page 848 for repairing tops.

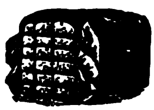
Fig. 1—Lubricating oil tank. This tank can be used for engine oil and general lubricating oil. It is made of galvanized steel and holds 60 gallons. Fitted with a positive action force pump. The advantage is that it keeps the oil covered and free from grit and dirt. The Bowser Co. of Ft. Wayne, Ind. make a more elaborate affair.

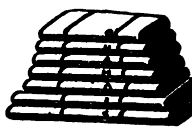
Fig. 2 — The cross oil filter will save oil which is wasted by filtering the used oil through this filter. It will also rid the oil of grit and mineral substances.

Fig. 3 — A waste can is required by the insurance companies, instead of throwing greasy, oily, inflammable waste on the floor, it is placed in this can. Every garage should have this waste can.

Fig. 4—The Dover gasoline and radiator filler will prevent spilling and is very easy to handle. It holds 5 gallons. It is not advisable to put gasoline in the same vessel used for water, but if it is necessary, then place a chamois skin in the funnel, pour the gasoline through it. No water will then pass into the gasoline tank.

Fig. 5—Illustrates a smaller size of dover radiator and gasoline filler — advisable to have one each for gasoline and water. This filler is also suitable for lubricating oil.



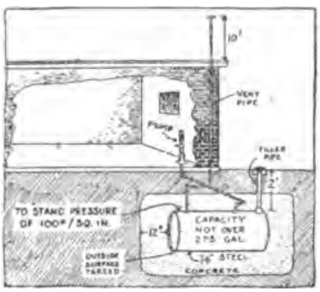


In selecting sponges, chamois and waste, it is advisable to use only the best.

Waste usually comes in bales of 50 or 100 pounds. It is economy to buy waste by the bale. Nothing but the very best white waste is suitable for automobile work. When waste has been used and ready to throw away, place it in a can, see Figure 3.

Chamois Skins are used for washing and cleaning the body and fine surfaces. It is a difficult matter to obtain a good genuine chamois skin, but it is worth the difference in price to get the best. The French chamois skin seems to be the most durable and pliable. Chamois skins come in sizes 28x32 inches and 19x21. A package of chamois generally contain a dozen.

Sponges often times contain sand and grit, especially the cheaper grade. Many cars have received scratches which cannot be removed by using the cheap gritty sponge. The best sponge is the Rock Island Sheepswool sponges. They come in bales of 15, 25 30 and 50 pounds.



The gasoline storage tank to supply gasoline inside of garage to a pump placed away from the tank, requires special installation on account of the insurance. The tank can be placed in the ground 18 inches below the surface. The Insurance Co.'s are very strict. The above plan is one that passes inspection in New York City.

Give tank 3 coats of asphaltum.

Address some of the storage tank manufacturers: Western Oil Pump & Tank Co., St. Louis Mo. O. K. Harry Steel Co., St. Louis, Mo. Wayne Oil Tank Co., Ft. Wayne, Ind. American Oil Pump Tank Co., Cincinnati, Ohio.

Fig. 10. Curb gasoline pump.

Fig. 10. A curb or road-side pump is shown. An electric light fixture with globe is placed above. The storage tank is buried under ground, usually as close to pump as possible—it is connected by a 1¼ inch suction pipe with foot valve placed at the end of suction pipe. Standard tanks range from 1 to 20 bbl. capacity. Parts are: foot valve, vented fill pipe with lock, suction pipe and gauge stick. (The Am. Oil Pump & Tank Co. Cincinnati O.)

An air pressure gasoline system is Mfgd. by Allen Pressure System Co., 1926 Broadway, N. Y.

Fire extinguishers should be in conspicious places about the garage. Gasoline often drips from a carburetor and back firing or a spark from a muffler will ignite the gasoline. Once a gasoline fire is started it is difficult to extinguish. Never use water; it will only serve to float the gasoline and spread the flame. If a fire extinguisher is not on hand, keep a box of fine earth or sand and dash over the flame. Flour will also do if nothing else is handy.

CHART NO. 244—Oil and Gasoline Equipment. Waste, Sponges and Chamois. Gasoline Storage Systems.

OIL TRANSFERRING SYSTEM

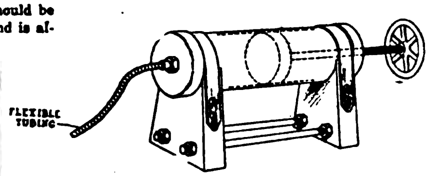
Oil may be most readily transferred from the barrel to the storage can by the aid of a differential pulley and suitable grab-hooks. The differential pulley may be fastened to the ceiling beams just over the oil storage room doorway, and if the storage cans are mounted on castors in the manner shown, they may be easily rolled under the suspended barrel, a hole drilled in the bung, and the oil transferred without further attention. The oil storage room shown in the sketch has several valuable features. First, the oil may be locked up, and is only accessible to the proper persons; secondly, the upper part contains a shelf in which the surplus stock of heavy oils and greases are stored.–

OIL-SETTLING TANK

The oil drained from the crankcase is usually a dead loss, as it is unfit for further motor use. It is, however, suitable for lubrication of farm machinery or such light implements as the lawnmower and the wheelbarrow, and may be reclaimed by the settling tank shown. The old oil is poured into the tank as fast as it collects and the sediment allowed to drop to the bottom, the clean oil rising to the top and being drawn off as required. The resale price should be made low to attract the trade, and is almost a clear profit.—

REPAIRSHOP PIT

A concrete repair pit, the depth of which may be varied, is illustrated. Ledges are provided at different heights and boards may be placed across, giving the mechanic free access to the work. Much of the dampness of this type of pit is removed by the wooden floor and the space beneath. Several of the boards on one of the upper ledges may be left in place and used as shelves for the tools and for steps in getting into and out of the pit.—



A POWERFUL GREASE GUN

A powerful grease gun for filling universal joints and steering gears is illustrated. The barrel of the gun is a piece of 6-in. pipe about 16 in. long, and carries a metal piston having a single ring. This piston is forced downward through the action of a threaded rod, screwed into a cap at one end, and operated by a hand wheel. The other end of the barrel is likewise covered with a cap and carries a length of flexible tubing, through which the grease is forced to the part. The barrel is mounted on wooden uprights, and is large enough to permit one loading to supply several joints. The amount of grease used each time may be readily determined by weighing the gun before and after using

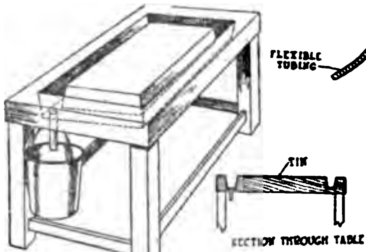


TABLE FOR WASHING PARTS

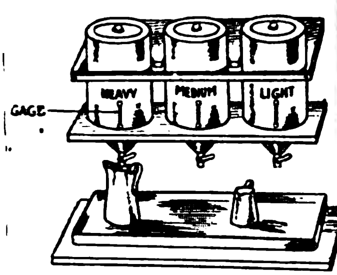
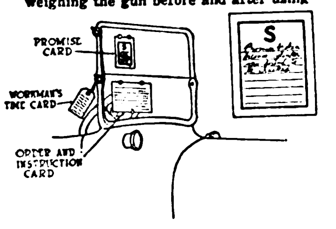
For any given quantity of gasoline a maximum of service with a minimum of waste in washing parts may be obtained by the use of the washing table shown. The table is covered with sheet metal, the feature being the trough around the edge which serves as a return to the pail for the washing liquid. In returning, much of the heavier grease is dropped and may be scraped up and deposited in a can kept for that purpose.



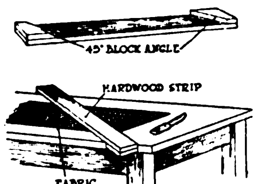
OIL-STORAGE TANKS

The common type of oil-storage tanks requires a pump and does not provide a convenient place for keeping the measures. Gravity flow is somewhat handier and the installation requires less floor space. A simple method of storing several grades of oil and having them on tap is illustrated. The tanks may be made by any tinsmith, and are provided with gage glasses that show at a glance the amount of oil on hand. The conical-shaped bottoms permit the draining of the last drop of oil and prevent the collection of any sediment. A shelf provided with a drip-pan offers a convenient place for keeping the receptacles.



PROMISE-RECORDING SYSTEM

A visible promise-recording system is shown. When the car reaches the repairshop floor, the work to be done is noted from the instruction card, and the job promised to be done at a certain time This promise is recorded by means of a heavy bordered card, pasted to the windshield and having the initial letter of the day of the promise printed at the top center. For example, if the car is promised for Saturday, a card having the letter "S" is used; if Monday, the letter "M." The foreman can then instantly see what must be got out each day and what promises are broken, and why.



CUTTING TIRE FABRIC

A simple but effective device for permitting fabric to be cut on the bias, with a wet knife, instead of shears, is illustrated. A hardwood strip, forming the straight edge, is placed 45 deg. across the tire repair bench, and each end fitted with hardwood angle blocks in the manner shown. These edges even up against the edge of the bench and secure a perfect 45 deg. cutting angle.–

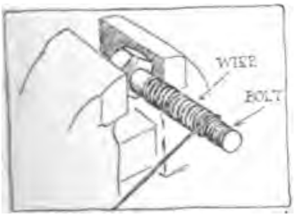


Fig. 4—How spring is made by winding wire around bolt

CHART NO. 244-A—Miscellaneous Additions for Garage and Shop. Many other useful shop devices are shown in Instruction 46-D.
(Motor World.)

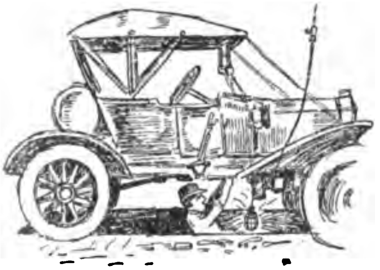

Fig. 1—A pit is provided in most shops. The car is rolled over the pit. Size of pit is usually 6 ft. long, 2 ft. 9 in. wide and 2 ft. 9in. deep.

A very well laid out plan for a pit is shown in chart 244-A.

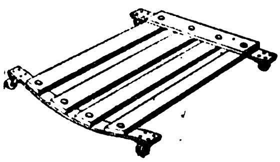

Fig. 3. Durable creeper. **This creeper is** easily made, and strong enough to permit a car to run over it without injury. Cross strips are 2x⅛ inch steel and bent slightly to give clearance for the swivel castors and yet keep body of creeper low. Slats are 4x¾ in. hard wood.

Fig. 5

Fig. 5A—The Continental adjustable engine stand.

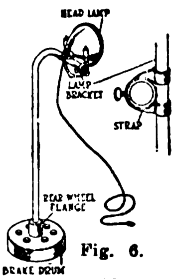

Fig. 6.

This portable service lamp was made both for night service in the shop, and for work on the road. A standard headlight, together with its bracket, is clamped to a pipe upright, bent as illustrated. This upright is fastened to a base that is an old rear wheel flange bolted to a brake drum. Current is derived either from direct connection with the storage battery or by plugging into the dash lamp circuit.—(Motor World.)

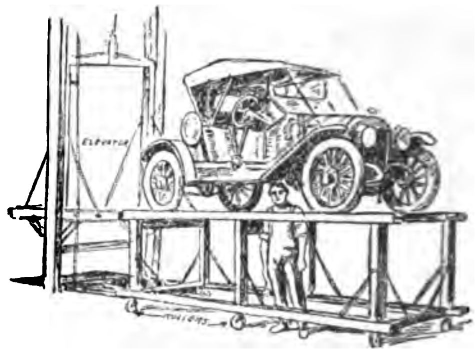

Fig. 2—Portable structure for working under cars where there is an elevator.

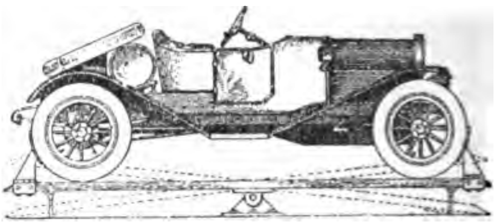

Fig. 4—A see-saw arrangement for working under car.

Fig. 1—An inspection pit is useful; placed at any convenient place where the auto can be run over it. The pit permits the repairman to get under the car and work.

The pits are usually made as per the dimensions under the illustrations. A mirror is very handy for throwing light in dark corners when working under a car.

Fig. 2—Where there is an elevator and no pit. The structure serves the same purpose as a pit with the additional advantages of being portable, more cleanly, and more accessible. It permits the workmen to perform most of their operations by daylight instead of subjecting them to the inefficient glare of an electric light bulb. No skids are required with this structure in any garage where an elevator is provided; the elevator with the vehicle upon it is simply brought to a stop at the height of the truck and the truck then adjusted so the car can be rolled upon it. Being mounted on casters, the truck can be moved easily to the lightest portion of the shop.

Fig. 4—A good many devices have been invented to aid in getting under a car for doing repair work. Where it is impossible to make a pit, something like the illustration will be found useful, and will answer the purpose. As will be seen it can be raised to rest in a horizontal position, or either the front or rear may be raised as required. When at an angle, the front or rear may be raised two feet. When in a horizontal position, as shown in the illustration, the elevation is about one foot. The apparatus consists of a light swinging runway upon which the car is pushed. When the repair work is at the forward end of the car the front is raised, and thus there is plenty of room to work. When the work to be done is at the rear of the car, the opposite incline is given. The method of fastening the car on the incline shows for itself. It consists of two hinged pieces which rests against the wheels.

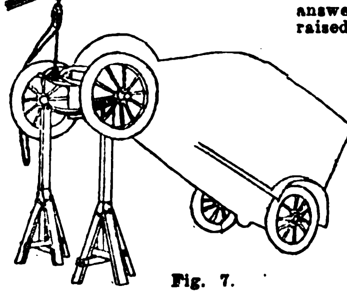

Fig. 7.

Fig. 7—Another method for working under a car: Front end of car is hoisted by chain and special made wood jacks are placed under axle. The stands or jacks must be designed for least space possible—in order to give working room between them.

Fig. 5—The Continental assembly and welding table greatly helps to speed up all kinds and types of assembly work. It is not necessary to continually change the position of the article which is being worked on, in respect to the table, as the table may be revolved and the work comes to the right position. The table is instantly locked.

CHART NO. 245—Different Methods for Working under Cars.

Fig. 4—A chain hoist and frame as shown above is a necessity in a repair shop for lifting engines from chassis. The frame is made of heavy iron pipe with rollers, also see other charts under "Repair Shop Hints," Inst. 46-D.

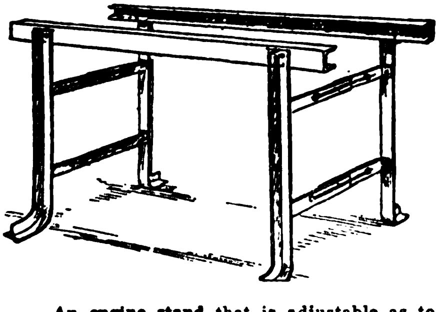
The feature of this crane, which is made of structural steel and mounted on four castors, is that the overhanging arm is pivoted so that it may be swung from side to side. The block and tackle may be attached at three points on this arm. The swivel feature of the arm is a convenience in removing or replacing an engine, as it allows for fine adjustment or facilitates removal by enabling the engine to be swung out over the chassis with a minimum of effort. The construction is very substantial.

This is an ideal shop crane or hoist which can be moved from place to place. By running the lower part under front of car, the engine or parts can be lifted. Manufactured by The United Engine and Manufacturing Co., Hanover, Pa., another type called the "Canton" is supplied by the St. Louis Machinist Supply Co., St. Louis, Missouri.

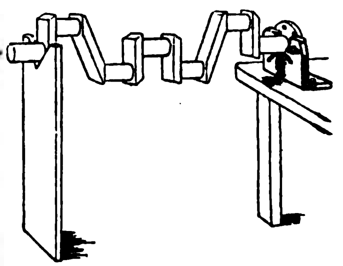
Fig. 5—Portable hose swing rack for washing cars. This rack is made of standard pipe and fittings. The illustration gives an idea of its construction.

A wash is usually made about 12 or 14 ft. wide and about 15 or 18 feet long. It is made of granitoid arranged so that the water flows to a trap in the center for draining.

A washer with several hose outlets, which meets all requirements and is not likely to get out of order is made out of four lengths of hose suspended from pipe connections at the four corners of the wash rack. Each hose is connected to a plug valve which is spring-closed and opened by a slight pull on the hose. The advantage of the four-hose construction is that it is simple, not apt to get out of order, and allows more than one man to work on a car.



An engine stand that is adjustable as to width, and that is very light yet strong, can be made out of structural steel. The top members are 4-inch channels, the legs 2x3 inch T iron, and the cross members are made of flat stock ¼x1 inch.



When the crankshaft has been removed and the connecting-rod bearings are to be scraped, the bracket shown will be found convenient for holding the crankshaft on the bench. It is merely a metal angle with slots for bolts which go through the crankshaft flange. The support at the other end is a notched board.

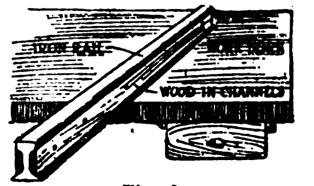


Fig. 6.

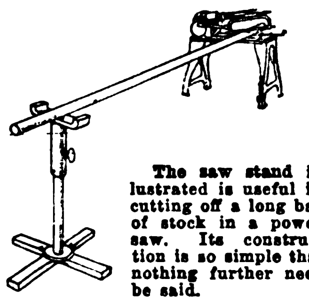
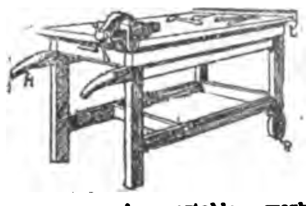
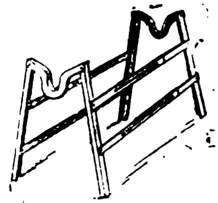
An iron rail is a useful device for any shop.



The saw stand illustrated is useful in cutting off a long bar of stock in a power saw. Its construction is so simple that nothing further need be said.



A portable work bench—an improvement would be to add shelves underneath for parts. Note the rollers (R) and handles (H).



Another home made stand, for working on axles.

CHART NO. 246—Time and Labor Saving Home Made Devices for the Shop and Garage—also see charts 302 to 308-A.

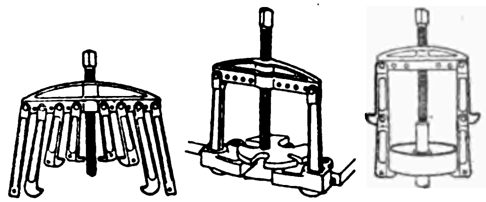


Fig. 1 Fig. 2 Fig. 3

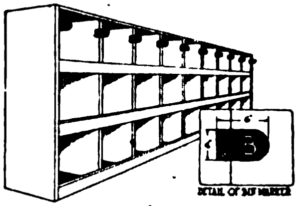
Crane wheel pullers—a complete outfit is shown.

Fig. 1—the complete outfit with various length attachments; **Fig. 2**—a special attachment which makes an arbor press; **Fig. 3**—removing a fly wheel. Mfg'd by—Crane Puller Co., Arlington Mass., also write to W. E. Prudden Hdw. Co., 864, 8th ave. N. Y., for information on another type of wheel puller.

Pulling a wheel from a rusted axle is a bigger job than it appears. If the axle is greased before the wheel is put on, the probabilities are it will come off readily, if not it will, more than likely, be a task. A wheel puller can be bought of any auto supply house or one can be made by local blacksmith. Every repair shop needs a wheel puller.

A wheel puller can also be utilized for removing fly wheels, transmissions, gears, collars, pulleys couplings, marine propellers, etc.



This stock bin marker permits ready location of any bin in the stock room. It is a sheet metal tag, bearing the number of the bin to which it is attached. As it projects out into the aisle, and is large enough to be easily read, the location of any desired bin may be seen at a glance.

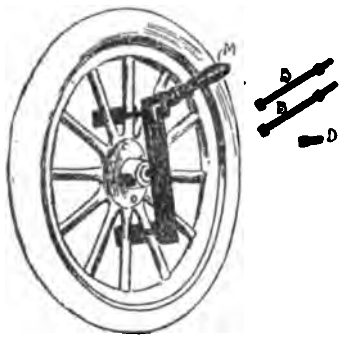


Fig. 4—This makeshift wheel puller is made from two long bolts B, with nuts, a short thick bolt D and three pieces of iron drilled as shown. These parts are applied to the wheel with the short pieces of iron behind the spokes of the wheel, and the bolt D communicating between the bar and the end of the axle shaft. By taking up evenly on the two nuts with the wrench M and occasionally striking the bar opposite the bolt D with a hammer, a very stubborn wheel can be easily removed.

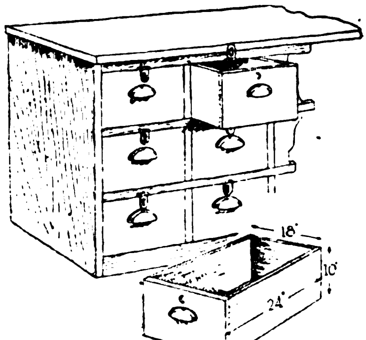
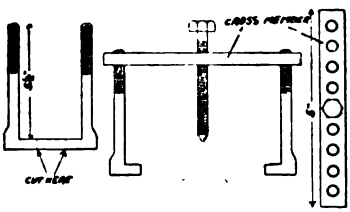
This tool box is made integral with its base, and is mounted on castors, so that it may be taken to the side of the car upon which the work is to be done. The tool box proper is shallow, and contains a space for the more common tools, in addition to several small compartments for miscellaneous parts. The more valuable, precise and less frequently used tools are kept in a drawer beneath the box, which is locked unless in use.



Substantial drawers of large size provide convenient means for storing parts removed from cars that are being repaired. The usual method is to place the parts on the bench, but this is objectionable because there is always danger of them being mislaid or used on other cars. A drawer 10x18x24 in. is large enough to take all the ordinary parts, such as bolts, nuts, washers, carburetor, magneto, pistons, connecting-rods, bearings, etc. The drawer may be placed at the side of the car and as soon as all the parts have been removed it may be put back in the cabinet. A padlock safe-guards the parts until they are needed again. These drawers also aid in keeping the shop neat and protect the parts from dirt. The top of the cabinet may be used as a bench or table.

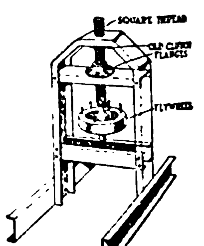


Wheel Puller Made from Spring Clip.

Fig. 5.—A home-made gear wheel puller: First get a piece of soft iron or steel. This piece must be 5 in. long and 1 in. square. Then find a long spring clip, the longer the better; cut the clip in two pieces at the bottom about ½ in. from the inside of the clip, then you have the arms completed.

To make the cross-member have a piece of iron or steel 1 in. square by 5 in. in length; drill a hole in the center and tap threads for a ½ in. bolt. Next you can drill three or more smaller holes on each side of the large center hole and tap these holes out to fit the threads on the spring clip; then you have an adjustment for three or more gears.

This home-made arbor press is made of channel sections from an old frame. It comprises an inverted U-shaped member, supported in an upright position on the channel base as shown. The overall height is about 5½ ft. and the width 4 ft. The pressure screw is carried on two large nuts that are old clutch flanges tapped out, both the screw and the nuts having square threads. An old flywheel, keyed to the lower end of the pressure screw serves as a hand wheel, and is provided with vertical pins so that a pinch bar may be used to increase the leverage.



(Arbor presses are manufactured by Weaver Manufacturing Co., Springfield Illinois.)

CHART NO. 247—Useful Devices for the Shop—continued.

(Motor World.)

Supplies for the Repair Shop Stock Room.

Assortment as illustrated above. Can be secured of Supply Houses or Stevens Co., 375 Broadway, N. Y.

Asbestos—sheet and wicking.
Babbitt metal—for bearings.
Blue, Prussian, for "spotting in," page 642.
Brake lining—see page 615, 688.
Bolts—stove and carriage, assorted sizes.
Body polish—brass and nickel.
Brushes—paint, scratch, file.
Brushes—for generator and motor.
Bushings—for crankshafts.
Chalk line—for aligning wheels.
Cotter-pins—assorted sizes.
Carbide—in cans.
Cocks—compression and pet.
Chamois—for washing car.
Cylinder oil—light, medium, heavy.
Cup and transmission grease.
Candle wicking—for pump packing.
Clamps—hose and screw.
Celluloid sheets—for top curtains.
Cloth—crocus and emery.
Drill rods and drills—
Dry cells—testing not less than 25 amperes.
Ells—brass; for gasoline and oil lines.
Emery cloth—No. 00 to No. 1.
Electric lamp bulbs—see pages 543, 434.
Felt—sheet and washers.
Fibre—sheet and block.
Flux—for soldering aluminum and brass.
Graphite—powdered and flake.
Grease cups—⅛, ⅜.
Gaskets assorted—copper, asbestos lined for valve caps, carburetor, exhaust and inlet manifold, spark plugs, etc. See pages 717, 239.
Gas tips—½ and 1 ft. sizes.
Gas tank keys—for Prestolite gas tanks.
Hand washing compound—
Hemp wicking—for packing.
Hose—for radiator and gas.
Hose clamps—for radiator hose.
Inner valve parts—for tire valves.
Iron—bars and rods.
Iron—sheet
Inner shoes—for blow outs.
Key stock—in bars.
Kerosene—for general cleaning.
Keys—Woodruff, Whitney and straight.
Leather—(heavy) for under radiator and bodies and refacing cone clutches.
Lard oil—for thread cuttings, tapping and drilling.
Lock washers—¼ to ⅝ in.
Moboline—for packing.
Neats foot oil—for clutch.
Nails—assorted.
Outer shoes—for cuts in casing.
Pipe plugs—iron and brass ⅛ to ¾ inch.
Paper—heavy brown, sand, emery.
Platinum points—for interrupters, and magneto.
Rivets—iron and copper, assorted.
Rubber—sheet packing 1/16 to 3/16.
Rubber—tubing for gas, air, tire, hose, (see tire).
Rubber—matting.
Sheet—iron, brass, copper, tin and lead.
Shims—laminated.
Solder—half and half, string and aluminum.
Soldering compound and acid.
Screws—machine, cap, lag, wood and set.
Steel rods—bar, tool.
Spark plugs—½ inch, S. A. E., metric (page 238).
Switches—push, snap.
Shellac—for gaskets, etc.
Spring—steel and assorted springs.
Steel bars: Few feet of ¼ inch, ⅜ inch, ½ inch, ⅝ inch, ¾ inch, ⅞ inch and 1 inch iron bars, also steel, brass and wire rods.
Tees—⅛, ¼, brass for gas lines.
Tacks—assorted sizes.
Tubing—copper, brass, for gas and oil lines ⅛, ¼ inch, this tubing generally comes hard, but can be annealed (softened) by heating it.
Tape—adhesive; for electric wiring.
Taper pins—¼ to ⅜ inch.
Unions—brass, ⅛ inch, and soldering connections for gasoline lines—page 608.
Valve grinding compound, see page 630.
Valves—for gasoline and oil lines, tire valves and oversize valves for engine.
Valve caps—for leading engines, valve caps for tire valves.
Wire—copper, brass, spring, piano, and insulated.
Wire—for wiring cars as; primary flexible cable and secondary cable.
Washers—punched, split, and brass.

Copper Gaskets for Spark Plugs.

S. A. E: ⅞" (inside di. ⅞; outside 1⅛").
Half inch: (inside di. [illegible]; o. s. di. 1 3/32").
Metric: (inside di. [illegible]; o. s. di. [illegible]").
See pages 238, 239 and 612.

Assorted Piston Rings

For older model cars. Can be secured of Stevens Co., New York, or any piston ring manufacturer. See foot note, page 655.

2¾ x 3/16: Saxon 16-17, Grant 14, Continental 16.
2⅞ x 3/16: Saxon 16-17, Haynes 17, Oldsmobile 17. Pathfinder 17, Grant 16, Scripps-Booth 15.
3⅛ x 3/16: Cadillac 15-16, Overland 16, Chalmers 15.
3 x 3/16: Buick Truck 14, Dort 15, Grant 16, King 16, Packard Twin 6-16.
3¼ x 3/16: Apperson, Dort, Chalmers, Hupmobile, Mitchell, Moon, Franklin.
3¼ x ¼: Velie, Overland, Moon 16, Continental.
3⅜ x 3/16: Hupmobile 15, Overland 17, Buick 17.
3½ x 3/16: Cole 16, Carter Car, Studebaker, Paige, Overland, Oldsmobile, Haynes, Hudson, Oakland, Velie.
3 11/16 x 3/16: Scripps-Booth, Chevrolet 490.
3¾ x ¼: Ford, Metz, Winton, Jeffry.
3⅝ x 3/16: Maxwell 14-15-16-17 Model 25.
3⅞ x 3/16: Dodge (all), Metz.
3¾ x 3/16: Buick 14-15-16, Mercer, Hupmobile 16-17, Velie.
4 x ¼: Maxwell Model 35, Mitchell, Packard, Pierce-Arrow.
4⅛ x ¼: Abbott, Detroit, Allen, Chase, Crawford, Mitchell, Republic, Studebaker.

CHART 274-A—Some of the Supplies for the Stock Room. The selection and quantity is governed by the demand. See also, pages 601, 608 and 609.

See also, pages 717, 472, 614.

Valve adjusters for placing over the valve end of Ford engine valves to take up wear and lessen noise.

Hose clamps are necessary. This type is the Sherman wrought brass clamp to fit radiator hose below.

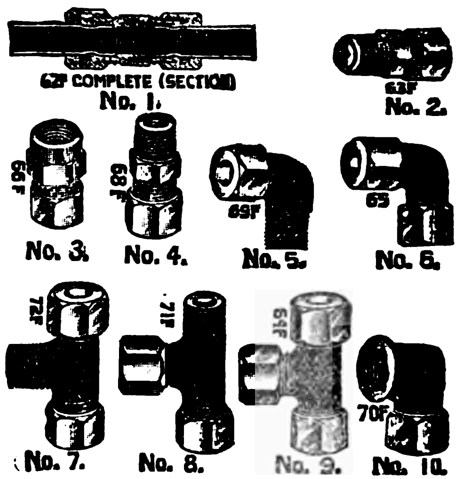


Fig. 1—Solderless fittings for gasoline, gas lines, etc. (1) Showing how ends are drawn together. (2) Check valve, straight. (3) Tapered female ⅛ inch pipe one end. (4) Nipple union, male ⅛ inch pipe one end. (5) Elbow male. (6) Elbow coupling. (7) Tee coupling on opposite ends, ⅛ inch pipe thread (male) on other. (8) Tee angle coupling, male thread one end. (9) Tee angle on three ends. (10) Elbow coupling on one end, female pipe thread on other.

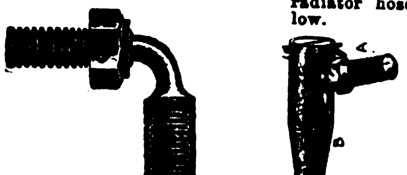
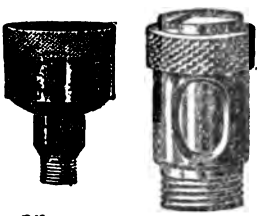


Spark and throttle ball-joints used for connecting magneto timer levers and carburetor throttle lever, with levers on steering wheel. They eliminate all lost motion and give more perfect control. Screw end fits the timer and carburetor lever, tapped hole fits connecting rod.—They come 25 in a box, assorted (Stevens & Co..)



Grease and oil cups ought to be carried in stock room.

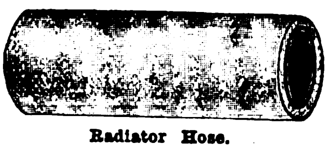
Sizes of grease. cups run as follows:
000—⅛ in. pipe thread.
00—⅛ in. pipe thread.
0—⅛—or ¼ in. pipe thread.

Diameter of 000 is ¾ in., 00 is 1 in., and 0 is 1¼ in.

Oil cups run as follows:
No. 1—¼x32 thread, ⅝ in diameter.
No. 2—$\frac{5}{16}$x32 thread, $\frac{7}{16}$ in. diameter.
No. 3—⅜x24 thread, ½ in. diameter.
No. 4—$\frac{7}{16}$x24 thread, $\frac{9}{16}$ in. diameter.

Exhaust "cut-outs" are frequently demanded by auto owners. Every stock room ought to have a few sizes in stock.

Many cars now days are equipped with **tire carriers.** Here is one easily applied and with lock, for the Ford.



Radiator Hose.

(3 and 4 ply steam hose.)

4 ply hose	Price
¾ in. inside diam., per foot......	$ .50
1 in. inside diam., per foot......	.50
1⅛ in. inside diam., per foot......	.55
1¼ in. inside diam., per foot......	.62
1½ in. inside diam., per foot......	.75
1¾ in. inside diam., per foot......	.87
2 in. inside diam., per foot......	1.00
2¼ in. inside diam., per foot......	1.12
2½ in. inside diam., per foot......	1.25
2¾ in. inside diam., per foot......	1.35
3 in. inside diam., per foot......	1.50

Rubber hose for radiator should be carried in all stock rooms.

Oil Cans

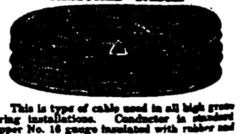
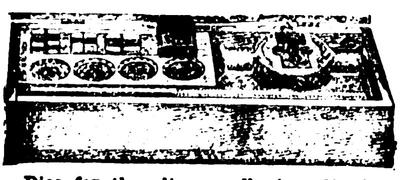
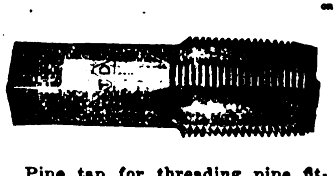
ARMORED CABLE



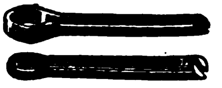
This is type of cable used in all high grade wiring installations. Conductor is standard copper No. 16 gauge insulated with rubber and varnished fabric. Sherardized protecting cover on outside. Diameter, 3/16 in.



Dies for threading small pipe, ⅛, ¼, ⅜, ½, inch, outfit No. 0-260 made by Greenfield Tap & Die Corporation, Greenfield, Mass.



Pipe tap for threading pipe fittings etc., (see pages 704, 702).

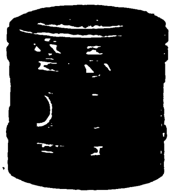


An assortment of cotter pins, ¾, 1, 1¼, 1¾ and 2 in. lengths.

CHART NO. 247-B—Miscellaneous Fittings and Supplies for Garage and Shop.

Pistons; Standard and Oversize.

Pistons can be purchased in "standard" and "oversize" diameters. A standard size piston is the original diameter of engine cylinder, less the standard clearance (page 651).



Piston

The oversize piston is fitted to a cylinder when cylinder is enlarged, by re-boring, re-grinding or reaming, as explained on pages 654, 653.

When a cylinder is cut or scored, but not worn and is not out of round, then the score or cut can be "filled," as per foot note, page 653. In this instance the original or standard size piston can be refitted, if of the correct clearance.

If cylinder is worn out of round, and it is usually out of round when worn, then it will be necessary to enlarge the cylinder bore as per pages 654 and 651, and fit "oversize pistons" and "oversize piston rings".

Usually, when a cylinder wears, it wears where the rings travel, which is the upper part of cylinder. The lower part of cylinder may measure true, but when measuring the upper part, where the rings travel it will more than likely be out of true. By observing the rings, if there is a black spot on the ring and it is not smooth, either the ring has lost its tension at this point or cylinder is out of round. Result is, the cylinder leaks compression, pumps oil, fouls the spark plugs with oil and consumes oil and gasoline all out of proportion with the power delivered.

When a piston is too loose or cylinder is worn, then a "piston slap" develops, which not only causes a knock, as explained on page 637, but in all probabilities the cylinder will be worn at the upper point, on one side, due to the explosion pressure forcing the piston at an angle, constantly against wall of cylinder, thus permitting gasoline to pass into crank case and thin the oil and also permits oil to pass into combustion chamber. A bent connecting rod will **also cause a piston slap,** see also, page 659.

To test a cylinder to see if it is out of round, an inside *micrometer (page 649) is **necessary.** The cylinder should be tested from top to bottom carefully and thoroughly. If out of round .003" or more at any one point, then the only safe remedy is to have it reground and new pistons ground to fit. After an engine is run 20,000 to 30,000 miles it most likely needs regrinding.

To test a piston, an outside micrometer is used. The piston of course, will measure less at the top than the skirt, (page 651), but it should be true and if not true, or if clearance between piston and cylinder wall is greater than normal, then a new piston should be ground to fit cylinder. Pistons out of round cause oil pockets which causes an excess of oil to enter combustion chamber.

Oversize pistons can be secured in sizes from .005", .010", .015", .020", .031", .046", .062", larger than the original or standard size of piston. Cylinders are seldom ground less than .010" oversize. One concern who make a specialty of oversize pistons, rings wrist-pins and grinds cylinders is the H. & H. Machine Co., St. Louis, Mo.

Therefore, the following will determine the necessity of enlarging a cylinder: (1) Cylinder condition; (2) Piston condition.

To determine how much to enlarge a cylinder, depends upon how much out of round, how badly worn, or how deep the cut is. Usually, one of the dimensions above, or the S. A. E. standard oversize for pistons, per pages 653, 654 will meet all conditions. One must be careful in enlarging a cylinder, that the wall of cylinder is thick enough to stand the enlargement.

Ford pistons, for instance, the standard size is 3¾" di. and fits cylinder with a clearance of .003" and is .010" smaller at the top than at the skirt, to allow for heat expansion—see also, pages 791, 792, 655.

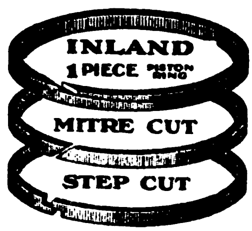
Ford oversize pistons can be secured of any Ford branch in oversizes as follows: 3¾"+.0025"; +.03125; +.033. By referring to page 541, note .03125" is equal to 1/32", and this is about as large as is safe to enlarge. The .033" size piston is supplied to be lapped in cylinder, when cylinder is enlarged to .03125" and after it is worn.

When sending a cylinder away to be re-ground, send the pistons also, but remove the valves and all parts. **When ordering pistons and you do not possess a micrometer,** cut a 3/16" bar of steel, filing both ends smooth to fit cylinder, at smallest point and number each bar for each cylinder.

The best plan is to have cylinders reground and have new pistons ground to fit each individual cylinder, with new rings, and in this way you will obtain a **job that will give full power to engine.** After having cylinders reground and pistons and rings fitted, it is necessary to run engine the first 500 miles, not over 15 m. p. h. and use a lot of oil.

Piston Rings: Oversize.

Oversize piston rings must be fitted to pistons when oversize pistons are fitted to cylinder. The oversizes of piston rings are: .005", .010", .015", .020", .031", .046", .062", the same as the pistons. There are a great number of different types of rings. Three kinds of ring gaps are shown in illustration.



Illustrating three different kinds of ring gaps.

Should ring grooves be worn more than .005" clearance as per pages 649, 655, then groove should be re-grooved on the lathe to take a 1/64" **oversize width ring,** that is, if it is worn so much that it leaks.

The ring gap clearance is given on page 649. Often times, however, the repairman will test ring at bottom of cylinder for gap clearance, but when ring is pushed up into cylinder where the rings travel, if cylinder is worn at this point, the ring will have too great a clearance or gap, therefore it is important to measure cylinder to determine. If worn slightly, then gap should be given less clearance at bottom of cylinder so it will have proper clearance where it travels—however, this is only a make shift arrangement—if cylinders are worn they need regrinding and will leak in spite of all you can do.

Miscellaneous Oversize Material.

Piston pins, oversize, are cheaper to use than rebushing a piston. Simply ream bushing, when a piston pin is loose and fit an oversize pin. (Can be secured of H. & H. Machine Co., St. Louis, Mo.)

Oversize valve stems, as on the Ford, where there is no provision made to put in cast iron bushings, is necessary when valves become noisy and air leaks into cylinder through inlet valve, causing missing at low speeds.

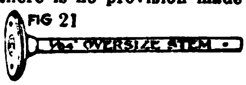


FIG 21

The guide is reamed 1/64" oversize and a 1/64" oversize valve stem fitted with .002 or .003" clearance.

Oversize valve tappets and also oversize cylinder head bolts can be secured of Stevens Co., 375 Broadway, N. Y.

CHART NO. 247-BB.—Pistons, Rings and Valve Stems; Standard and Oversize.

For aluminum pistons, see pages 645, 651, 792. *See page 698, how to read a micrometer.

Money Making Additions To a Garage.

Rectifiers for charging storage batteries, see pages 465, 463 and 864-K.

Motor-generator sets for charging storage batteries, see pages 462 and 864-L.

Decarbonizing outfit; see pages 624, 726, 727.

Oxy-Acetylene outfit; see pages 727, 726, 720.

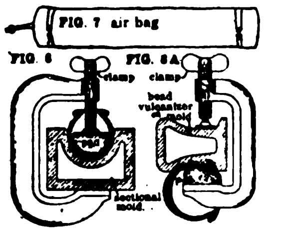
Air compressor outfit per page 564.

Cylinder reboring machine, a profitable investment, see pages 653, 654, 616. See also **Top Repairing**, page 847.

Tire repairing is one of the best investments, see page 574 and below.

Vulcanizers, Tools and Tire Repair Material.

There are two methods of preparing a tire to vulcanize; the "sectional" method as explained on page 573 and the "wrapped tread" method as per page 575.



When the sectional method is used there are two methods of holding tire in the mold; by a "clamp" as per fig. 8 and by an "air bag" as per fig. 7, and fig. 29, page 574, which expands the tire.

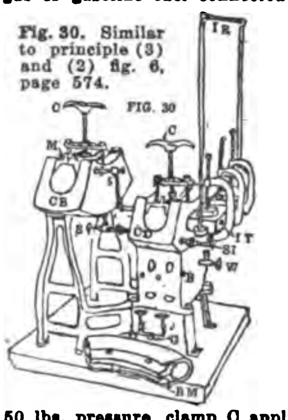
There are also two methods of repairing side-wall and bead repair; by use of "air-bag" and a "bead mold" per fig. 29, page 474, and by use of a "clamp" and "bead mold," per fig. 8A.

The electric vulcanizer, fig. 11, and the Shaler steam vulcanizer; fig. 2, page 574, vulcanizes a tire repair by the "wrapped tread" method as per page 575. Air bags are not used, but inside molds are inserted for inside repairs and outside molds, or hot plates, for outside repairs.

A Sectional Steam Vulcanizer.

The model 6 F (A. K.) vulcanizer, fig. 30, suitable for small repair shops in towns where there are a fairly good number of 4½" and 5" tires, vulcanizes by the "sectional" method with which air bags are used. Steam is generated in boiler B, by gas or gasoline fuel connected at (G).

Fig. 30. Similar to principle (3) and (2) fig. 6, page 574.



There are two cavity molds, OB for 4½", 5" tires and OD for 4", 3½" tires. Tires 3" size can be vulcanized by placing the 3" mold BM in the mold OD.. These molds will vulcanize "inside" and "outside" of tire also "side wall" and "bead" repairs. See fig. 29, page 574, and note the bead mold, also M, fig. 30.

After tire is prepared to be vulcanized (see page 573) an air bag is inserted, then placed in mold OB. Air bag is then inflated to 50 lbs. pressure, clamp O applied and steam turned into mold at S.

Where there is considerable repairing the **inside repair mold or patch** (4) fig. 6, page 574 is used. This is also handy for thoroughly drying out tires before vulcanizing.

Inner tubes are vulcanized by placing over rack (1 R) and part to be vulcanized is placed on plate (1 T) through which steam passes.

Cost of Tire Repair Outfit.

1,	model 6F vulcanizer (fig. 30)	$245.00
5,	airbags, 3" to 5" x 16" long	22.70
1,	gal. No. 1086 vul. cement	2.40
1,	qt. No. 1043 cold patching cement	.67
1,	lot inner tube valve patches	1.50
5,	lbs. *tread stock (cures gray)	5.00
10,	lbs. *tread stock (cures black)	10.00
5,	lbs. inner tube *repair stock (red)	7.50
2,	lbs. inner tube *repair stock (gray)	3.00
2,	lbs. inner tube *repair stock, cured on one side only, for inside reinforcement.	3.00

*The above list is the Williams double head open end wrench per fig. 3 above. *Numbers 21 to 45 will fit U. S. standard nuts and bolt head.

*Numbers 721 to 739B will fit cap screw heads; U. S. or S. A. E.

Open End Wrenches.

Probably the most abused, least considered and yet the most indispensable tool in the kit of the mechanic is the wrench, the solid open-ended wrench, known to the British mechanician as the fixed spanner and known in the United States as the machinists' wrench.

Of the many kinds of wrenches, the cheapest, strongest, most efficient and most durable is the open end wrench. This style of wrench varies in quality and price in the following order; gray iron castings, malleable iron castings, sheet steel stamped and steel drop forgings. The drop forged wrench is superior. See illustrations for proper name of the popular type of open-end wrenches.

Open end wrenches are used on cap screws, bolt heads and nuts.

They may be divided into two general classes, the U. S. S. and S. A. E. The only difference between them is the width of opening between the jaws.

A standard wrench for a ½" U. S. S. bolt will not fit a ½" S. A. E. cap screw and vice versa.

The S. A. E. wrenches are usually of the "cap screw size" and the U. S. S. wrenches are of the "U. S. S. bolt and nut size." Table 96 explains and also gives the various sizes for automobile work. The head is always larger on a U. S. S. bolt than on a cap screw.

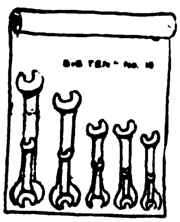
Markings — Wrenches are usually marked with the size on each end. They are also marked with the manufacturers number, this number is an indication to its size, see table 96.

Probably the most universally used wrench is the Williams wrench, as per table 96.

How to find the size wrench to fit an S. A. E. cap screw head. See table 97, chart 247-DD.

How to find the size wrench to fit a standard bolt and nut—see table 98, chart 247-DD, or refer to table 96 on this page for additional information.

Garage Wrench Set.



Williams "Big 10" wrench assortment for general automobile work—illustrated to the left and tabulated as to sizes below. Note it is a recommended assortment taken from the above list (table 96). The St. Louis Machinist Supply Co., St. Louis, carry full line of these wrenches—also other Supply Houses.

All dimensions in inches.

****Spark Plug Wrench.**

No. 1. The 7/8 inch end of this wrench fits all standard spark plugs, such as the Spitfire, Reliance, Rajah, Red Head and many others, while the 1 inch end fits the Sootless, Reliance, 7/8 in. Herz, Bosch and others.

No. 2. The 1 1/8 inch end fits all standard spark plugs of the large hex type such as the Champion, De Luxe, and others. (Stevens Co, N. Y.)

S. A. E. Spark Plug Shell Sizes.

The illustrations to the right, show the two S. A. E. spark plug shells. It will be noticed that the diameter of the hexagon part of shells differ. The "small hex." measures 7/8 inch across the flat and the "large hex." measures 1 1/8 inch. Reference to table 96, chart 247D, will show that the No. 784 wrench will fit both sizes.

S. A. E. spark plugs—are all 7/8—18, meaning that the outside diameter is 7/8 inch and there are 18 threads to the inch. See page 288 for difference in spark plug threads and explanation of spark plug sizes. Gaskets must be used with the S. A. E. spark plugs. See pages 289 and 607 for size gaskets to use.

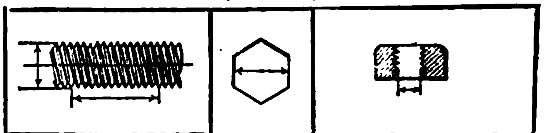
Note table 102, page 703—a 7/8 S. A. E. plug requires a special tap cutting 18 threads—whereas the standard S. A. E. 7/8 thread is 14 threads to the inch.

TABLE 98.

U. S. Standard Bolt Size; Head and Nut.

This table gives—(first column), di. of bolt or screw; (second column), threads per inch; (third column), di. across head; (fourth column) size of hole in thousandth of an inch; (fifth column), size drill to use for tapping hole (see also chart 285-B).

Mill means the "milled size" of head of screw or bolt or the opening in an open end wrench.



Diameter of Tap.	Threads per Inch.	Mill.	Exact Size of Hole.	Tap Drill Used.

ALL DIMENSIONS BELOW SHOULDER ARE IDENTICAL FOR BOTH SPARK PLUG SHELLS

†Butterfield screw plate set No. 10, consisting of parts shown in illustration. Dies and taps to cut S. A. E. and U. S. S. threads as enumerated in the lid of box. (Butterfield Co., Derby Line, Vt.)

CHART NO. 247-DD—S. A. E. and U. S. Standards of Screw and Bolt Sizes. S. A. E. Spark Plug Sizes. Spark Plug Wrenches—see pages 701 to 707, for threads, taps, dies, drills, etc.

*The diameter of bolts and cap screws is one-one thousandth of an inch less than nominal diameter.
**See also page 611. †See also page 795 for a Ford screw plate set. See also page 704. 705, 703.

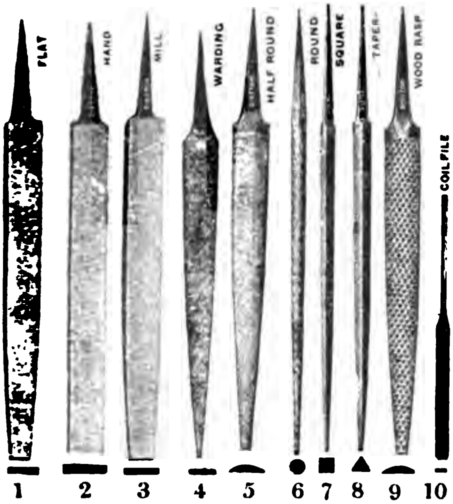

Fig. 1. Shapes of files in general use.

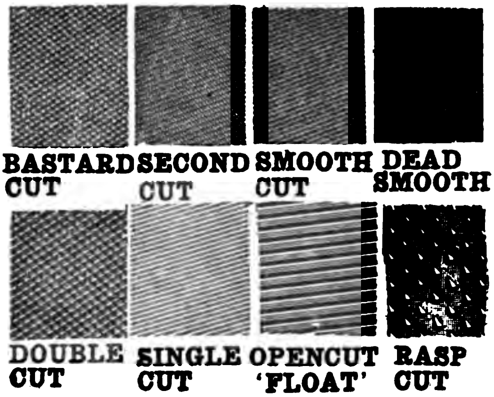

Fig. 2. The top row illustrates the different cutting grades files can be obtained; closer the teeth are together, finer the cut.

Lower row illustrates different methods of cutting teeth on files.

Files.

Kinds: There are many different kinds of files, but we will deal principally with those used for metal work and suitable for automobile repair shops.

Shapes of the files in general use are shown in fig. 1.

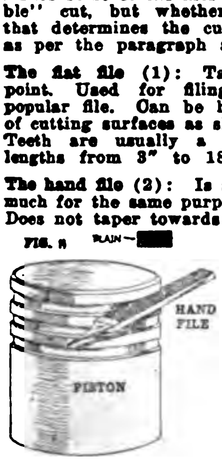
Cutting surfaces are shown in upper row, fig. 2. The coarsest metal cutting file is the "bastard-cut," the next is the "second-cut," next "smooth-cut," then "dead-smooth." Note that the finer the cut, closer the teeth are together. Coarse cutting files are used for soft metal or for removing quite a bit of metal and finer cut files are used for finishing or for harder metals.

Method of cutting teeth on a file: The teeth can be "double-cut" or "single-cut," but this does not interest the purchaser, as the manufacturer makes some of the files "single" and some "double" cut, but whether made either, the point that determines the cutting surface of a file is as per the paragraph above.

The flat file (1): Tapers, but not to a fine point. Used for filing flat surfaces. A very popular file. Can be had in any of the grades of cutting surfaces as shown in upper row, fig. 2. Teeth are usually a "double-cut." Comes in lengths from 3" to 18".

The hand file (2): Is also a flat file. Used very much for the same purposes as the "flat" file (1). Does not taper towards its end but does taper in thickness. This file can also be had in different grades of cutting surfaces. Teeth are usually "double-cut." There is one point however, where it differs. It has one or both edges plain (not cut at all), called "safe-edge." It would be suitable for beveling piston ring grooves per fig. 8. Lengths 3" to 16".

FIG. 8



Mill file (3): Is also a flat file. Used very much for the same purposes as the "flat" and "hand" file, but is of a cheaper make. Teeth are usually a "single-cut." Can be had in the different grades of cutting surfaces, but one point to remember about a "mill" file is that it is one grade finer cut than a "flat" or "hand" file, that is, if you call for a "mill" file with a "bastard-cut," it will be equal to a "hand," or "flat" file of a "second-cut." Lengths, 3" to 18".

Warding file (4): Is a flat file, but very thin, about half the thickness of other flat files of same length. It tapers sharply to a point towards its end. Used for work where space is limited. Can be had in different grades of cut. Teeth are usually "double-cut." Lengths, 3" to 10".

Half-round file (5): Tapers. Can be had in different grades of cutting surfaces. Teeth usually "double-cut" on one side and "single-cut" on the convex or round side. Used for work curved in shape and flat side used for flat work. Lengths, 3" to 18".

Round file (6): Tapers. Used for enlarging round holes, etc. Is usually a "bastard-cut." A small round file is known as a "rat tail" file. Lengths, 4" to 18".

Square file (7): Tapers. Usually a "bastard-cut." Teeth "double-cut." Used principally for enlarging apertures square in shape or rectangular. Lengths, 3" to 18".

Square "blunt" file is a square file which does not taper, but preserves its sectional shape from point to tang. It is used for finishing and enlarging mortises, key-ways, or splines. Usually "batard-cut." "Double-cut." Lengths, 10" to 20".

Triangular files (8): Comes in many different names as "three-square," "handsaw taper single cut," handsaw taper double cut," "slim taper" and "extra slim taper."

The three-square file tapers and teeth are usually "double-cut" with cutting surfaces mostly "bastard." Used for filing out square corners, filing taps, cutters, cutting steel tubing, notching round bars, etc. Lengths, 3" to 18".

The handsaw taper single cut file, tapers to a small point. Teeth "single-cut." Usually a "second-cut." Used for sharpening handsaws. The three-square file is not suitable for sharpening hand saws. Lengths, 3" to 10".

The handsaw taper double cut file is another triangular file with teeth "double-cut" and "second-cut" surface. Used for filing fine toothed hand and metal workers' hack saws, which are harder than wood saws. Lengths, 3" to 6".

The slim taper. Teeth are "single-cut" with "second-cut" surface. It tapers and is triangular in shape but very light, in other respects like the "handsaw file." It has superseded the regular handsaw file as it has a greater sweep or stroke. Lengths, 3" to 10".

Extra slim taper. Lighter stock than the slim taper. Teeth usually "single-cut" with "second-cut" surface. Generally tapers but occasionally blunt. Lengths, 4" to 8".

—continued on page 614.

CHART NO. 247-E...Files. See also pages 614 and 708.

Note: See page 615 for Socket Wrenches, which were formerly on this page. See page 612 for Tap & Dies.

—Files—continued from page 613.

Other triangular files are the "bandsaw file" for filing the teeth of a bandsaw. The "cantsaw file" for filing cross-cut saw teeth and the "ginsaw file" which is a 4", three square, single-cut.

Wood rasp file (9): Is a very coarse cut file. Note the "rasp-cut" in fig. 2. Rasp files can be had with teeth shaped as shown, but in the different grades of finess of cuts as "coarse," "bastard," "second-cut" and "smooth." Can also be had in flat and half-round shapes. They are used for various purposes as for wood cabinet work, wheelwright, carriage and to some extent by plumbers and marbleworkers.

Coil file (10): A very fine, flat file made especially for dressing down vibrator and screw points on ignition coils and platinum interrupter points on magnetos and timers.

Files To Use For Different Work.

Larger the work, larger the file. For **flat surfaces**, use the "hand," "flat" or "mill" file.

If work is in a **thin narrow space**, use the warding file. If **interior work curved or square**, use the round, half-round and square file.

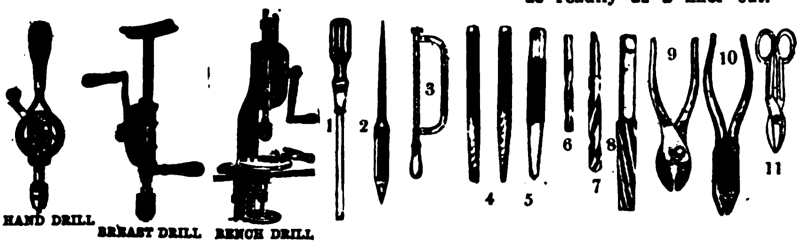
For cast iron, use "bastard-cut" to begin the work and finish with a "second-cut." Cast iron is softer than steel.

For soft steel, use a "second-cut" to begin the work and finish with a "smooth-cut." If a "mill" file is used, see seventh paragraph, page 613.

For hard steel, use a "smooth-cut," finish with a "dead-smooth."

Brass or bronze, use a "bastard-cut" and finish with a "second" or "smooth-cut."

Babbitt, aluminum, lead and soft metals, use a "bastard-cut." A popular file used for soft metals is a "float" or "open-cut" file, which has wide, deep open cut teeth which does not fill up as readily as a finer cut.



1—Screw driver.
2—Soldering iron.
3—Hack saw.
4—Chisels.
5—Center punch.
6—Straight shank drill (for hand and breast drill).
7—Taper shank drill (for drill press).
8—Reamer.
9—Gas pliers.
10—Cutting pliers.
11—Tinners shears.

Wrenches

Wrenches	Price
16 in. pipe wrench	$2.30
12 in. pipe wrench	1.60
6 in. pipe wrench	1.15
16 in. monkey wrench	2.55
12 in. monkey wrench	1.65
6 in. monkey wrench	.85
Set double end S-wrenches	2.30
Set 15 deg. double end	2.45
Spark plug socket	.60
Ratchet handle socket set	24.00
Adjustable 6 in. end wrench	1.00
Adjustable 8 in. end wrench	1.30
Narrow-jaw monkey wrench	.85
Set speed wrenches	7.00

Files

12 in. bastard cut, flat	$0.56
12 in. bastard cut, half round	.75
10 in. bastard cut, round	.45
10 in. bastard cut, square	.38
10 in. bastard cut, three cornered	.30
8 in. second cut, flat	.40
6 in. second cut, half round	.30
6 in. finishing cut, flat	.40
8 in. finishing cut, half round	.36
8 in finishing cut, three cornered	.25
8 in. finishing cut, rat tail	.70

Internal micrometer and extensions	10.60
Micrometer, 2 in.	10.60
Micrometer, 2 in.	15.25
Micrometer, 1 in.	10.40

Shears

Tinners' snips	$1.40
Heavy shears	2.10
Bolt cutters	2.00

Hammers

Rawhide mallet	1.65
Lead hammer mold	2.10
Straight pien, 4 oz.	.65
Ball pien, 1-2 lb.	.60
Ball pien, 1 lb.	1.00
Ball pien, 2 lb.	1.40
Blacksmith's sledge, 12 lb.	2.00
Blacksmith's, 4 lb.	1.30

Screwdrivers

Screwdrivers	Price
Small jeweler's	$0.40
6-in. blade	.85
10-in. blade	1.30
12-in. blade	1.75
Offset	.30
T-handle, large	2.30

Bench Equipment

Small bench anvil	$2.60
Swivel vise	17.00
Medium pipe vise	3.70
Surface plate	5.40
Machinists' clamps	7.00
C-clamps	6.00
Surface gage	2.15
Straightedge	4.30
Scriber	3.65

Chisels

Cape, large	$0.25
Cape, medium	.26
Cape, small	.26
Chipping, large	.40
Chipping, medium	.35
Chipping, small	.36
Round nose, large	.40
Round nose, medium	.35
Round nose, small	.36
Cotter pin puller	.15
Diamond point, large	.30
Diamond point, medium	.35
Diamond point, small	.30
Center punch, large	.45
Center punch, medium	.36
Center punch, small	.30
Drift pins, 1-16 to 3-4 by 16ths	2.40

Pliers

Combination 8 in.	$1.50
Combination 6 in.	1.30
Piston ring expanding	1.15
Side cutting, parallel jaws	1.40
Cotter pin	1.10

Miscellaneous Tools

Wheel and gear pullers	$12.60
Valve spring lifter	2.65
Breast drill, two speed	11.40
Valve seat reamer set	70.00
Soldering copper, large	2.75
Soldering copper, small	1.30
Gasoline blow torch	6.00
Hand drill, small	2.65
Belt punch	.60
Hacksaw frame and blades	6.00
Small hand vise	2.30
Oil stone	2.65
Three bearing scrapers	1.85
Three carbon scrapers	1.10
Pickup pliers	.65
Gasket cutter	12.50
Portable electric drill and valve grinding attachment	120.00
Piston ring compressor	.65
Total	$[illegible]

Hammers: A—machinists ball pein; B—riveting; C—tinners riveting; D—rawhide mallet; E—engineers hand hammer; F — blacksmiths hand hammer; G—blacksmiths sledge.

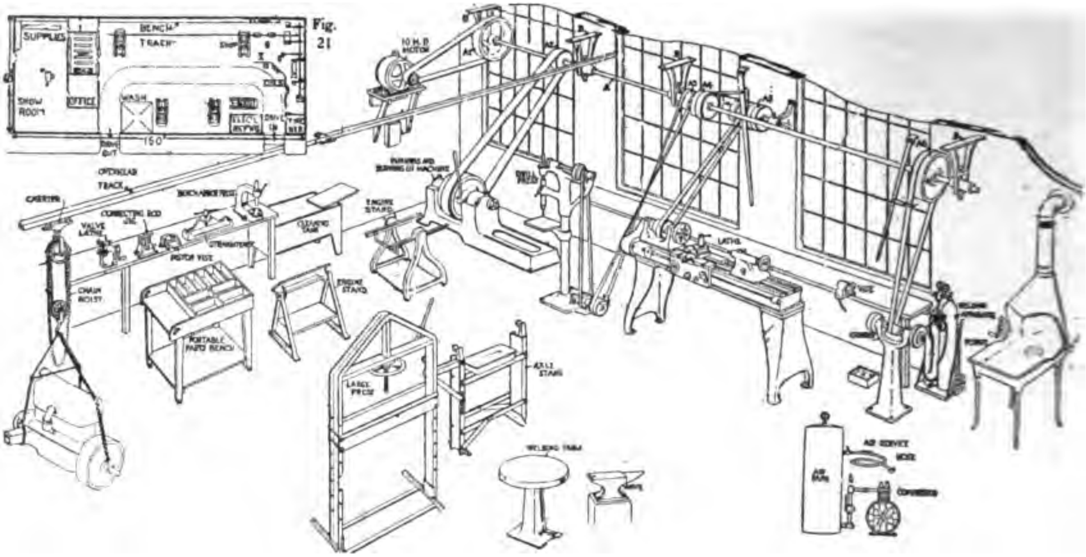

Fig. 21

Layout For Machine Tool Equipment of an Ideal Service Station for Average Town.

Fig. 21. Illustrates the layout for arrangement of a one floor salesroom, supply department, store room, office, machine shop, tire repair and electrical repair department as suggested in Motor Age.

Measurements are 60 ft. wide and 150 ft. long. Note the "drive in" and "drive out," also the track for the chain hoist to lift engine from the frame to work bench. Further note the space partitioned off for electrical repairing, tire repairing and battery charging.

The 10-hp. electric motor shown in the layout is designed to run at 1800 r.p.m. This will give the line shafting a speed of 400 r.p.m. With a 20-in. pulley on the shaft to drive the grinder, the latter will run at 2000 r.p.m., which is about 4000 ft. per minute surface speed for an emery wheel 7 in. in diameter.

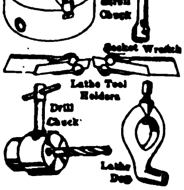
In this layout we have shown the air compressor driven by an individual electric motor instead of from the line shaft. The first cost of a 2-hp. electric motor required to drive the compressor will be a little more, but we believe this will be absorbed in the saving of current. Furthermore, there is the advantage of automatic starting and stopping, which cannot be done when the outfit is driven off the line shaft. A service station needs compressed air all the time, but it is not economy to keep a 10 or 15-hp. motor going just for the air line.

Machine Tool and Equipment

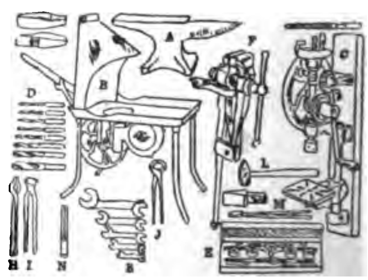
Line shaft, 30 ft. long, 1⅛ in. dia.	$ 11.00
Adjustable hangers	20.40
Electric motor, 10 hp.	335.00
Lathe countershaft..Included in lathe price	
Burning and running-in machine with fittings	490.00
Drill press, 14-in.	85.00
Lathe, 11¼-in. swing over carriage	818.00
Grinder	33.00
Welding table	70.00
Forge	27.00
Welding apparatus	90.00
Anvil	15.00
Air compressor outfit	247.00
Axle stand	36.00
Engine stand	50.00
Engine stand	49.00
Overhead track, 100 ft. with brackets	48.00
Overhead carrier and hoist	34.00
Valve lathe	3.75
Connecting rod jig	30.00
Piston vise	10.00
Crankshaft straightener	34.00
Bench arbor press	35.00
Cleaning tank	40.00
Large press	76.50
Total	$2,687.65

Pulley dimensions: A—line shaft 1⅛"; A-1, 32"; A-2, 20"; A-3, 7"; A-4, 10"; A-5, 14"; A-6, 20"; electric motor, 8"; grinder pulley 4".

Lathe Tools and Blacksmith Equipment.



***Lathe tools: 5", 3 jaw geared scroll chuck; socket wrench ⅜, ½ and ⅝"; lathe tool holders 4", to be used with 14" lathe; drill chuck with Nos. 1 and 2 arbor to hold drills up to ½"; lathe dogs, ½", 1", 1½" each.**



Blacksmith equipment; A—anvil 100 lb.; B—forge with 12" fan, 25x36" hearth; C—post drill; D—drills ⅛ to ⅝"; E—screw plate set; F—blacksmith vise; H—flat lip tongs; K—flat wrenches; L—3 lb. hammer.

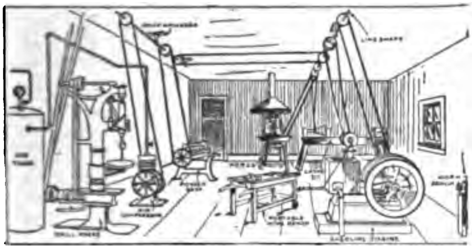
CHART NO. 247-H—Machine Shop Equipment for Large Shop.

*See page 711, how to make lathe tools. See page 472 for Equipment for Electrical Department.

The machinery equipment, together with a list of machinery necessary for a large or small shop is given on pages 616, 618.

Equipment for a fairly large shop in which almost any work can be done is shown on page 616.

Equipment for a smaller shop in which all average work can be done is shown on page 618.



The line shaft, shown in fig. 5, page 618 would porbably be arranged different. It is shown in one length, whereas it would likely be arranged in two sections or as shown above.

Approximate Cost of Equipment of a Small Shop.

Machinery shown in fig. 5, page 618, approximatley	$800.00
Lathe tools (page 616)	65.00
Large tools	80.00
Small tools	75.00
Miscellaneous	100.00
Total	$1,120.00

Air compressor outfit is important. The air pump could be operated from the line shaft, but if in active use it would be best to run it from a separate electric motor—see pages 564 and 563.

Other Money Making Equipment.

Battery charging and repair outfit, including motor-generator set or a rectifier, cadmium test outfit (see pages 864K and 863I)	$250.00
Tire repair and vulcanizing outfit (page 610)	375.00
Electrical testing instruments (pages 864H, I, J)	75.00
Oxygen carbon cleaning outfit (page 624)	25.00
Oxy-acetylene welding outfit	100.00
	$1,190.00

For a still smaller shop, a Tungar or other type rectifier could be used instead of a motor-generator set, together with a cadmium testing outfit for storage battery work, and electrical testing instruments of smaller size, as per the "portable outfit" on page 864I, for less money, where there is not very much work to be done.

The tire repair outfit could also be reduced to $150.00 by obtaining a smaller outfit as the one shown in fig. 11, page 610 and fig. 2, page 574.

Power to run the machinery could be a gasoline engine or electric motor. The electric motor is more convenient and can in many cities, be rented from the electric company.

Work benches should always be placed next to windows where there is light. It should measure at least 8 or 10 feet long, height about 3 feet and width 2 ft. 6 in. and made of 2 in. thick well seasoned pine, or better, birch. See also pages 596, fig. 8 and page 616.

Lathes for Repair Shop Work.

The choice of a lathe depends upon the amount of work and kind of work one proposes doing. If equipment is desired whereby one can make repairs on axles, axle housings, and fly wheels then a 16 in. swing 8 ft. bed lathe would be recommended*

A smaller lathe for work on bearing bushings, pins, grinding piston pins and bolts, a lathe with a 4 ft. bed and 6 in. swing is required.

Drill Press.

A large drill press, back-geared type, with a 16 in. table—for work such as reaming cylinders, drilling holes in frames and etc. will be required.

A sensitive drill press for light work, such as drilling cotter pin holes, small shafts and rods, such as those on the steering device, timer, etc. is very necessary.

Some of the manufacturers of drill presses are: Barnes Drill Co., Rockford, Ill.; W. P. Davis Co., Rochester, N. Y.; Champion Blower and Forge Co., Lancaster, Pa.; Oanedy-Otto Mfg. Co., Chicago Heights, Ill.; American Grinder Co., Milwaukee, Wis.

Portable electric drills (see illustration, page 563), are very handy for drilling holes in frames for attaching shock absorbers, horns, mufflers, etc.

Power Hack Saw.

Power hack saw (see fig. 5, page 618), are used for cutting all kinds of metal. They are made self feeding with automatic stop.

Manufacturers are: West Haven Mfg. Co., New Haven, Conn.; Millers-Falls Co., Miller Falls, Mass.; Goodell Pratt Co., Greenfield, Mass.

Chain Hoist.

The chain hoist is illustrated on page 616. They can be secured in capacities from ¼ to 1 ton, suitable for general automobile work. The lift varies from 6 ft. for the ¼ ton, 7 ft. for the ½ ton and 8 ft. for the 1 ton capacity.

Manufacturers are: The Edwin Harrington Sons & Co., Philadelphia, Pa.; Wright Mfg. Co., Lisboro, O.

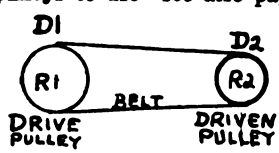
Emery Wheels and Stand.

The emery wheel is used principally for finishing up tool work, taking off metal and also for buffing and polishing brass parts. Two emery wheels No. 40 and No. 60 grade at least, should be secured, also cloth buffers for polishing.

A very compact electric emery wheel and buffer is made by the LeBron Electric Works, Omaha, Nebr.

†Diameter and Revolution Formula.

This formula will explain how to find the size of pulleys to use—see also page 563.



D1 × R1 ÷ D2 = R2.
D1 × R1 ÷ R2 = D2.
D2 × R2 ÷ R1 = D1.
D2 × R2 ÷ D1 = R1.
D1 represents diameter of driver.
D2 represents diameter of driven.
R1 represents revolutions of driver.
R2 represents revolutions of driven.

"How To Run a Lathe" and "First Year Lathe Work" are two 64 page pamphlets, fully illustrated —which will be supplied to readers of this book for 10c each. Address South Bend Lathe Works, South Bend, Ind., and mention that you have this book. †See also, page 568. *See advertisement of South Bend Lathe Works in back of book for cylinder boring attachment.

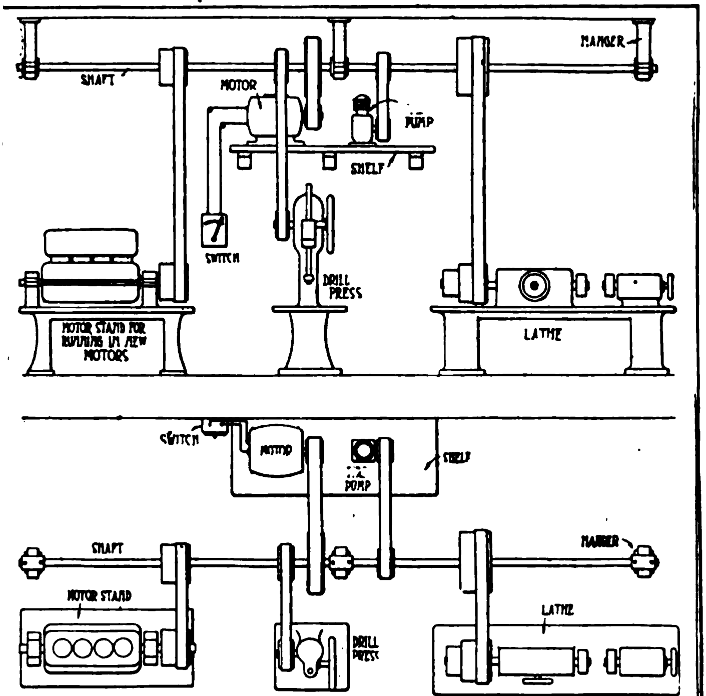


Fig. 4.—Suggested layout for small machine shop in corner of garage

Lay Out For a Small Machine Shop.

Fig. 4—Lay-out for small medium shop—driven by a 3 to 5 h.p. electric motor and with a motor stand for "running in" or "working in" engines after new rings are fitted, etc. The line shaft should revolve about 200 r.p.m. Line shaft is 15 to 20 ft. long with 3 hangers, 1⅜ or 1$\frac{7}{16}$ inch di.

Fig. 5 shows another lay-out: In the illustration (exaggerated) we have laid out a standard line of machinery suitable for a machine shop. The line shaft is arranged in a straight line, whereas for close quarters it may be necessary to place two line shafts.

Although a gasoline engine and an electric motor for power are both illustrated, only one is necessary; both are shown in order to explain method for belting if one or the other is used. The electric motor is usually placed on the ceiling or on a post or shelf.

The gasoline engine ought to be equipped with a clutch in the drive pulley or in the pulley on the line shaft.

Approximate Pieces of Machinery Equipment for a Small Shop.

1—20 inch drill press	$75.00 to 100.
1—16 in. x 6 ft. lathe	264.00
1—emery stand with 2, 6x1 wheels	20.00
1—sensitive drill press for small work	60.00
1—marvel No. 1, power hack saw	25.00
25'—line shafting and 4 drop hangers and belting	50.00
Compressed air outfit, belt driven from line shaft (see chart 287-B)	45.00

We will assume the electric motor is rented from the electric company. If not, add about $100 for electric motor or gasoline engine.

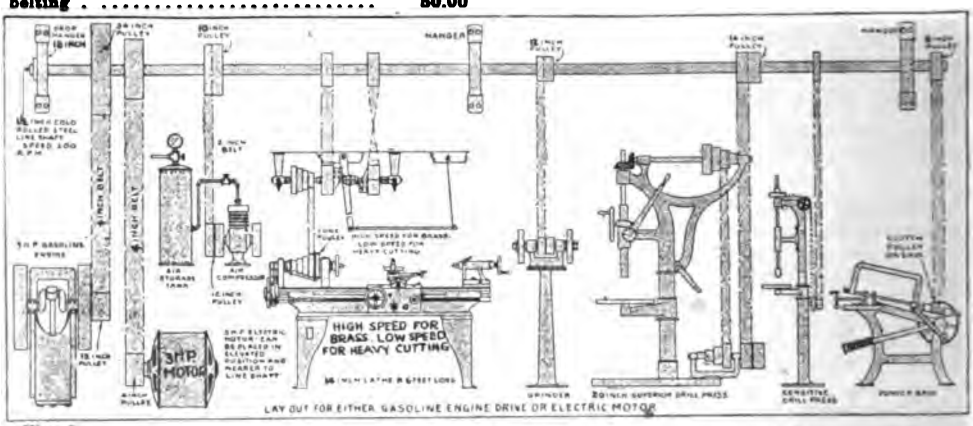

Fig. 5.

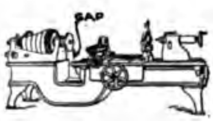
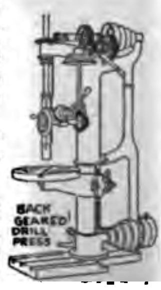
Shaft straightening press. While this press is made mainly for straightening shafts, it is also applicable for axle straightening as well. A tremendous power can be brought to bear, by the action of the long lever and heavy screw. A section of perfectly true shafting is centered between the adjustable tail stocks and used as a guide or measuring point as the shaft is being straightened.

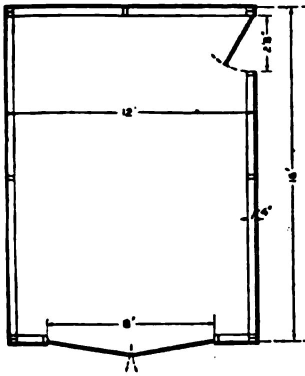
Back geared drill press. The advantage of the back gear feature, is obvious, as it is often very desirable to reverse the direction of rotation of a drill.



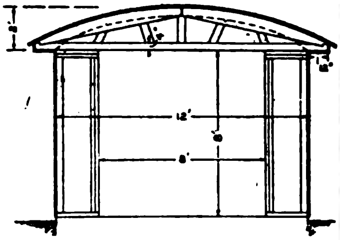
Gap-bed lathe. The distinguishing feature of this lathe is that the guides near the lathe head are cut away, thereby increasing considerably the size of the swing, without increasing the other dimensions. It is possible to handle much larger work with this style than could be handled on the regular type of the same dimensions.



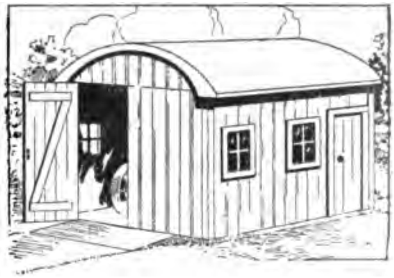
[CH]ART NO. 248—Lay-Out and Equipment of a Machine Shop for Average Automobile Work—
"How to Run a Lathe"—see foot note bottom of page 617.)

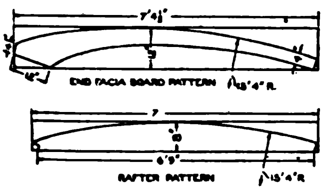


Floor Plan, Showing the Location of the Sills, Studs and Corner Posts on the Concrete Floor

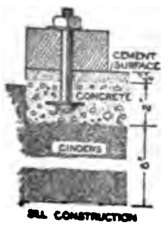


End Elevation, Showing the Rafter Construction and the Finishing Facia Boards on the Eaves





Pattern Layout for the Rafter Pieces and the Finishing Facia Boards for the Eaves at the Ends



SILL CONSTRUCTION

The home garage shown in the illustration is designed for housing one machine, and to give a little space about it so that a person can clean the exterior of the automobile and do small repairs.

The first thing to be considered is the foundation, or base, which is made of concrete. The earth should be excavated for a depth of 6 inches and to the exact dimensions given for the floor plan. The hole is then filled with cinders, well tamped in and leveled on top. A frame, about 4 inches high, is built up of cheap lumber, so that the space within measures 12 ft. wide and 16 ft. long, except at the double-door opening where a sloping runway is formed for the easy entrance of the automobile. A 2 inch layer of concrete—a mixture of 1 part cement, 2 parts sand, and 4 parts gravel, or crushed stone is placed on top of the cinders, and a neat mixture of cement and sand, ½ inch thick is placed on the concrete and made perfectly level. When putting in the concrete, ½ inch bolts, about 5 inches long are set in the edge with the threaded end extended about 3 inches above the upper surface of the cement and in line with the center of the 2 by 4 inch timber used as a sill. The detail of this construction is shown in the sketch. About four of these bolts should be set on each side, three on the end, and one on each side of the double doors.

The corner posts and studs are cut so that their length, together with the thickness of the sill and the two pieces for the plate, will measure 8 feet. This is the proper length to cut the boards without waste from standard lengths of lumber. After raising the corner posts and studs, and nailing the plate pieces on top, the siding boards are nailed on vertically to the plate and sill, and the battens nailed over the joints.

The rafters are built up in a manner similar to that used on large garages now so popular. Each one, or each pair, consists of a crosspiece that rests on top of the plates at the sides and is notched at the ends, to receive the ends of the convex rafter pieces. The pattern for one of these pieces, with dimensions, is shown in the drawing. After fitting the three main parts to form one rafter across the building, they are fastened together with short pieces of boards, which can be cut from scrap. The rafters are set on the plates 16 inches apart from center to center.

The sheathing boards are nailed to the curved edges of the rafters lengthwise, and as the material list calls for boards 12 feet long, one and one-half lengths will cover the rafters and allow 1 foot projection at each end for the eave. The facia boards are cut on a curve in the same manner as the rafter pieces, and the under side is cut as shown in the detail, so as to make a neat-appearing connection to the end of the frieze boards. Straight facia boards are fastened on the eaves, at the sides, in the same manner, and a frieze board nailed to the under side, the ends being finished, as shown in the detail drawing.

Prepared roofing is fastened to the sheathing in the usual manner, beginning the layers at the eave and finishing in the center, allowing the center piece to overlap on both sides.

The windows consist of four single casements, two being placed on each side. These can be of any size to suit the builder, and can be bought from a mill ready to be set into the openings cut for them.

The doors can be made up of the same material as that used for the siding and battened together, or, if a more elaborate door is desired, they can be purchased at a reasonable price, panelled and with a glass in the upper part. If paneled doors are used, 18 boards can be deducted from the siding-material list. The double doors will require fastenings at the center, and, in placing the concrete floor, a keeper should be set in the surface cement for the foot latch. The upper keeper can be attached to the end rafter crosspiece. The usual hardware is necessary for the small door at the opposite end.

A garage built up in this manner and well painted will last for years, and if it becomes necessary to move it, nothing will be lost except the concrete floor, as the building can be lifted from the bolts and taken away bodily.—(Popular Mechanics.)

Material List.

CONCRETE FLOORS:

2 bbls. cement.
4.5 cu. yd. cinders.
2.2 cu. yd. sand.
4.3 cu. yd. gravel

SILLS, PLATES AND STUDS:

6 pieces, 16 ft. long, 2 by 4 in.
4 pieces, 12 ft. long, 2 by 4 in.
20 pieces, 8 ft. long, 2 by 4 in.

SIDING:

90 boards, 8 ft. long, ⅞ by 8 in.
90 battens, 8 ft. long.

RAFTERS:

10 boards, 14 ft. long, ⅞ by 8 in.
10 boards, 14 ft. long, ⅞ by 4 in.

ROOFING:

Enough sheathing boards, 12 ft. long to cover 260 sq. ft.
Enough prepared roofing to cover 260 sq. ft.

WINDOWS...

4 single casements.

FINISHING PIECES:

2 frieze boards, 18 ft. long, ⅞ by 1 ft.
2 facia boards, 18 ft. long, ⅞ by 4 in.
4 facia boards, 8 ft. long, ⅞ by 1 ft.
8 corner boards, 8 ft. long, ⅞ by 4 in.
6 door facing boards, 8 ft. long, ⅞ by 4 in.

HARDWARE:

1 pair of door hinges.
1 door lock.
3 pair of heavy door hinges.
1 foot latch.
1 upper latch.
1 large door lock.
10 lb. 20-penny nails.
20 lb. 8-penny nails.
10 bolts, with double washers, ½ by 5 in.

CHART NO. 249—Building a Private Garage.

INSTRUCTION No. 46.

REPAIRING AND ADJUSTING: Overhauling a Car. Cleaning and Lubricating. Removing Carbon. Causes of Loss of Power. Compression Tests. Refacing and Reseating Valves. Adjusting and Timing of Valves. Bearings; constructions, adjustment and repairs. Pistons and Rings; fitting, testing, etc. Engine Knocks; how to locate and remedy. Enlarging Cylinders.

*What Constitutes a Car Overhaul.

Automobile overhauling is essentially a process of general cleaning, inspection, tightening-up and readjusting, involving, perhaps, some minor replacements, all of which will be explained further on in this instruction.

Engine.

Test compression; test for knocks, clean carbon, grind valves, adjust valve clearance, fit new rings if necessary, re-bore cylinders if necessary, take up on bearings; check the valve timing, examine valve springs, examine gaskets.

Ignition and wiring—test the ignition timing, test battery and electrical apparatus, clean spark plugs and adjust gaps, also clean, oil and adjust and tighten the generator and starter nuts etc., see that all ground connections are tight.

Clean engine: by flushing out old oil with kerosene as explained on page 201. Refill oil pan with a good grade of oil.

Miscellaneous engine parts; examine water pump, see if water hose requires replacement (see page 193); examine intake and exhaust manifolds and see that gaskets and joints are tight, (see page 192,) tighten all bolts and nuts.

Radiator.

The radiator should be disconnected and a stream of water forced through it for several hours. If scale exists, cleaning can be done with a solution of one pound ordinary washing soda and five gallons of water allowing to stand for an hour, (see page 191.)

Carburetion.

The carburetor should be removed and thoroughly cleaned and tested for float leak. Examine the gasoline line and see that all joints are tight.

Clutch and Transmissions.

The clutch is one part to receive attention, and here the repairman should resort to a large extent to the maker's instruction book if it is still at hand. The cone clutches are usually faced with leather or fabric. The leather can be cleaned with a dry cloth and then painted very lightly and evenly with neatsfoot oil. The fabric facing can be given a squirt-gunful of kerosene. Be free with oil on all the clutch connections and take especial care that the clutch thrust bearing is properly fed. Oil all connections from the clutch pedal lever to the clutch proper. Do not take up on the clutch spring unless you are certain it is needed.

With wet-plate clutches the housing should be flushed with kerosene and the engine turned over a number of times. At the same time the engine is turned over some one should push the clutch pedal in and out. This works the kerosene around the plates and tends to remove any gummy deposits. Then drain the housing, and repeat the operation. That finished, fill to the required level with oil. Usually 1 pint is used with one-half pint of kerosene.

With a dry-plate clutch the only thing that may be needed is a cleaning with kerosene, to remove gum. However, use a squirt gun in this case. No matter what the type of clutch be free with oil at all the various connections.

Look for small oil holes which are clogged with dirt. Oil the clutch cross shaft, the clutch collar and all the parts which move.

Universal joint:. Back of the clutch or transmission, there may be a universal. Clean it thoroughly with kerosene whether it is exposed or housed. Allow this to dry and then pack with graphite. If you have no graphite, get some or use a good grade of grease.

Next, proceed to the transmission. Drain the old lubricant, replace the drain plug, and remove the cover if there is one. Fill the case half full of kerosene and with a clean cloth mop it. This is a dirty job but it will be worth your while, because the gear-set usually is neglected throughout the year and is required to give efficient service with oil that is perhaps a year old. With the case clean add a grade of oil as recommended by the manufacturers, or see page 203. Don't put too much oil in the case. There usually is a level plug but if there is none, allow the level to be about up to the shaft of the highest or upper gears.

*See page 527 for testing a car before overhauing. See also page 594. See page 794 for prices usually charged for Ford work and page 795, "inspection after overhauling."

Running Gear Parts.

Wheels: First in order come the wheels. The car has been jacked up, and the next step is to see that the wheels run true on their bearings. There are many ways of doing this. A good way is to sight with one eye closed, while the wheel is revolving. Any irregularity in wheel movement is easily detected. However, sometimes the rim is bent a little and one will imagine the wheel is running untrue. Grip the wheel firmly with both hands and test for side play and up-and-down play by pushing and pulling on the wheel in all directions.

A loose bearing usually causes this trouble and in many cases the looseness can be overcome by tightening the nut slightly. Some times new bearings are needed, because they are worn excessively.

Align the wheels as explained in charts 278 and 279.

The steering assembly, brakes and other parts require the same sort of attention and will be taken up in their separate order further on.

Rear axle should be cleaned and lubricated and the drive pinion tested as to it's relation with the drive gear on the differential. If noisy, it is probably loose and requires adjustment as will be explained under "Adjustment of rear axle gears."

Cleaning Engine.

We will take up the usual and common work required on all engines. We will first start with cleaning and lubricating the engine and greasing a car. About every nine* cars out of ten require cleaning and greasing.

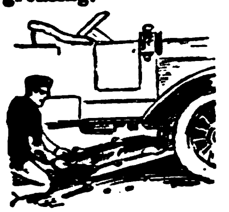


Fig. 1 — Remove drip pan and clean with gasoline or kerosene.

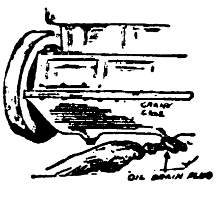

Fig. 2 — Remove drain plug at bottom of crank case to drain old oil.

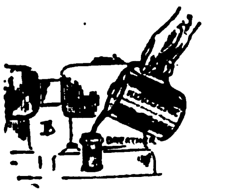

Fig. 3—Flush the crank case with kerosene. Pour through the place along side of engine where lubricating oil is poured in — called the "breather."

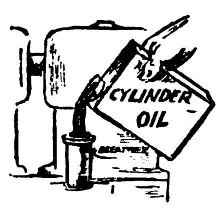

Fig. 4 — After crank case is cleaned and drain plug screwed in, put the best grade of cylinder oil in the crank case.

First start with the engine. Remove the drip pan, (fig. 1). Next unscrew the drain plug or open drain cock under the crank case. Drain all oil into a pan of some kind. This oil can then be placed in the oil filter, (fig. 2, chart 244) and used over again in the transmission, when mixed with grease or graphite.

It will be found that when oil stops dripping; if the starting crank is turned a few times by hand a little more oil will be found to flow. The best time to drain oil is after engine has been run and heated and oil is thinned. (Also see page 201.)

When the oil has ceased to come from the crank case the drain plug is replaced. It is not screwed tightly home as it is soon to be removed again. Now pour 2 quarts of kerosene into the breather pipe, (fig. 3) and run the engine again for about 15 seconds. If it is not in running condition open the compression cocks on the cylinder and spin it rapidly by hand. The longer this is done the better, but it is an arduous task and if kept up for a minute or so will be all that is necessary. The drain plug is now removed again and the kerosene is entirely drained out. The plug is screwed back and fresh oil provided.

Put fresh cylinder oil in crank case: In filling the crank case use only the very best cylinder oil, (see lubrication, pages 201 and 200). A gauge is usually provided to show how much to place in the crank case. If not, fill the crank case until it is about even with the center of crank pin when on bottom center. **Don't fail to place drip pan back** and tighten up all nuts.

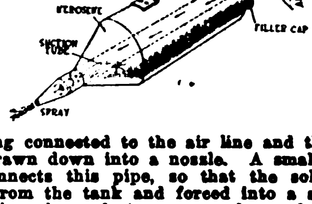
Note: Be sure all drain cocks are free by opening them and running a wire through.

The outside of engine and drip pan can be cleaned with gasoline. A brush dipped in gasoline to reach inaccessible places and also an oil gun to shoot gasoline in inaccessible places will suffice. The lighting of a match or any kind of flame, however, while cleaning should be prohibited.

A modern method for cleaning the engine is by means of a sprayer. In large shops compressed air is used quite extensively for all kinds of cleaning.

Home Made Engine Cleaner.

A gasoline or kerosene spray, acting under air pressure, will quickly remove dirt and grease from the engine or chassis. A device for forming this spray is shown. It comprises a metal tank, holding the cleaning solution, and an aspirator for forming the spray. This aspirator is a copper pipe, passing through the center of the tank, one



end being connected to the air line and the other being drawn down into a nozzle. A small copper tube connects this pipe, so that the solution is drawn from the tank and forced into a spray by the passing air—a foot pump can be used to inject air if pressure is not on hand. See also page 740, fig. 7, and page 744 for others.

*See Instruction 36—Cleaning and Washing a Car.

Clean The Exhaust System.

This cleaning should include the exhaust manifold, pipe and muffler. The latter should be taken apart and the parts soaked in kerosene over night. The pipe and manifold may be cleaned by drawing through a pack of kerosene-soaked waste attached to a long wire.

Keeping Oil Off the Radiator Hose.

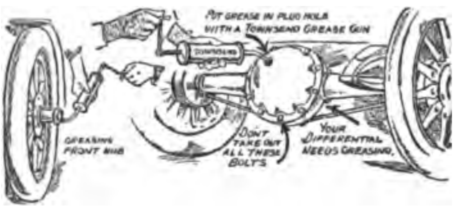
To prevent oil from rotting the inlet hose from radiator to pump I have been giving the hose a coat of shellac and then a couple of layers of tape and shellac over that. The shellac keeps the oil away from the rubber.

***Parts Washing Table.**

This is large enough to permit any part of the car to be cleaned. But more important, it may be moved to the job. A wooden basin, or sink, 5 ft. long, 2 ft. wide and 6 in. deep is mounted on legs, and lined with tin. A drain plug is placed in the center, permitting the dirty cleaning solution to be drawn off into a pail hanging beneath the stand. Gasoline may be used for cleaning parts, but kerosene is cheaper and safer.

Greasing a Car.

One of the first things to do when starting to grease a car is to screw down on the grease cups, which forces out all grease therein, the cap is then unscrewed, grease cup refilled and cap placed back—but don't cross thread the caps or they will work loose and be lost.



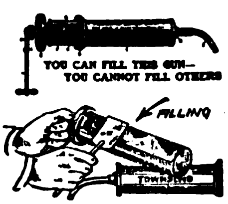


Fig. 2. The differential can be greased in the same manner as well as the wheels (if grease is required, see page 204 and 208.) This grease gun is thoroughly reliable and ought to be in every repair kit.

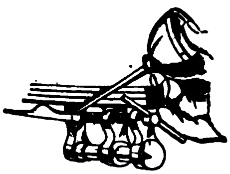
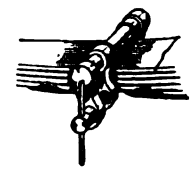
In greasing such places as the shaft of a cone type clutch (through a plug hole), the differential and other places on a car where a grease cup is not provided, but where grease plug holes are provided the Townsend grease gun is an excellent device. You can grease the differential gears, the universal, and every part of the car in a few minutes time, without removing the covers and all of those nuts and bolts.

Lubrication of Springs.

A detail which, if attended to, conduces much to easy running of a car, is the oiling of those parts of the springs upon which the leaves move. It is becoming the practice to make provision for proper lubrication at this point, which is easily done by drilling a hole through each leaf, as otherwise it is not easy when the weight of the car is on them to introduce any oil into the interstices. Very frequently, however, rust is seen along the joints, showing that water can get in, at any rate, and oil will work its way in, too, if applied at the edges,



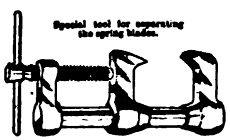
Lubricating the surface of the separated spring blades.



The same tool used as a temporary clamp to secure a broken spring.

but it will probably be found that this can be more easily done if the blades are separated by means of the special appliance illustrated herewith.

Rust in the springs affects their proper movement, and causes mysterious squeaks as well. The joints of the links connecting the upper and lower portions of the springs at each end should also have a little oil applied occasionally. It is when performing this duty that timely opportunity often occurs of observing defects of loose nuts or broken leaves in the springs. The nuts belonging to the clips which hold the spring on to the axle often display a tendency to work loose, and if this is not remedied the axle will be thrown out of line, with more or less serious consequences to tires and driving gear generally; or, if the front axle is in question, the steering may be affected.



Special tool for separating the spring blades.

If a car is overloaded much beyond its normal capacity, extra work will be thrown on the springs which may give rise to breakage when the car is being driven over bad roads. An extra leaf added to the springs is advisable for overloads. Considerable advantage to the life of the springs is obtained by having shock absorbers or buffer blocks fitted. (see spring covers, chart 236-E.)

Other parts of a car to lubricate and grease are shown on page 204.

*See also, page 741. Townsend Grease Gun is manufactured by The Townsend Co., Orange, N. J.

*Relation of Carbon to Lubricating Oil.

The oil film which protects the friction surfaces in your engine is hardly thicker than the page you are now reading.

It makes no difference how much oil you pour into your crank-case. The only oil that protects your engine is this thin film between the moving metal parts.

And this thin film is not the cool oil you pour into your crank-case. In use the oil heats quickly. Then the test comes.

Only oil of the highest quality will retain full lubricating efficiency under the heat of service.

Many oils break down under this heat. Part of the oil goes off in vapor, just as hot water gives off steam. With an oil film only .003 of an inch thick this vaporization must be reckoned with.

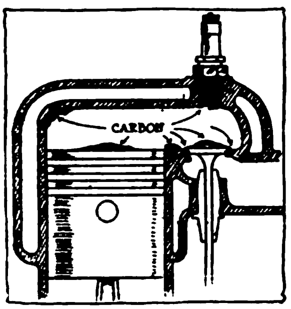
To get full protection, you must have a constant, full, even oil film. You must have an oil which will stand the heat of service.

The Cause of Carbon Deposit.

Due mostly to the use of poor grade of lubricating oil or too much oil, and quite often to an improper mixture of gas or too much gasoline being fed.

Carbon has many lodging places. It fouls spark plugs and kills the spark. It pits the valve seats and weakens compression. By accumulating on the piston heads and in the combustion chambers, it causes knocking and racks your engine with pre-ignition.

The amount of carbon deposited in your engine depends upon the carburetion and gasoline combustion and on the character of the gasoline as well as on the quality of the lubricating oil itself and the correctness of its body.



Showing points in cylinder where carbon deposits are most apt to gather.

As both gasoline and petroleum lubricating oils are chemical combinations of hydrogen and carbon, carbon is an essential element of each. See page 158.

Only the free (suspended) carbon can be taken out. To remove the carbon which is in combination with other chemical elements, constituting gasoline and oil would result in the destruction of the product itself.

Carbon deposit is likely to occur through incomplete combustion of the gasoline or through the destruction of the excess lubricating oil which will work into the combustion chamber if the oil is of incorrect body. "No carbon" oils do not exist.

To reduce carbon to a minimum, the lubricating oil must be of high quality and of correct body for the piston design and lubricating system of your engine. See page 200.

Lubricating oil adds materially to carbon deposit of an engine if the following conditions exist:

**1—Poorly fitting piston rings or scored piston rings and cylinders.

2—Carrying too high an oil level; using an oil that is not suited to the engine, both as regards body and quality, or carrying the pressure in a force-feed system at too high a point. See page 199.

†3—Allowing the oil in the crank-case or oiling system to deteriorate to the point that it is so thin that even a well-fitting piston ring will not prevent a surplus of oil from passing into the combustion chamber.

Relation of Carbon to Combustion.

An important consideration is the incomplete combustion of gasoline, for from this source a large proportion of carbon is deposited. When the charge of gasoline and air (the proportions of which are determined by the carburetor adjustment) is taken into the cylinder of a gas engine, it consists of hydrocarbon vapor and air. The oxygen in the air combines with the carbon and hydrogen of the gasoline and forms an explosive mixture. This mixture is fired, and after expansion the products of combustions are expelled from the cylinder through the exhaust valve.

If the amount of air entering the carburetor is not sufficient to insure complete combustion, we have what is known as a rich mixture. This is a slow-burning mixture rather than an explosive one and will cause excessive carbon deposit. For example, if the wick of an oil burning lamp is turned too high, too much oil will be drawn through the wick for the amount of air entering the lamp to form complete combustion. The lamp will smoke, and soot (which is carbon) will be deposited on the chimney.

This is exactly what happens in the cylinder of a gas engine. The products of incomplete combustion together with a portion of lubricating oil passing by the piston rings, deposit a certain amount of carbon in the combustion chamber. That portion of this carbon which does not pass out with the exhaust is baked on the cylinder heads, pistons and valves by the heat of explosion. This carbon deposit will build up very much more quickly if it has a bed to build up on, such as would be produced by a lubricating oil, which, when exposed to the heat of explosion, would leave a gummy deposit.

*Also see page 202.

**One cure for "scored" cylinders has been the judicious use of a special graphite lubricant. See page 205. The best plan however, is to have cylinder reground or soldered, see foot note, page 653.

†See page 653, "piston pumping oil," and page 735 a "carbon remover."

Methods For Removing Carbon From Cylinders and Pistons.

Scraping Method.

Fig. 1. To scrape carbon from a piston in this manner it is necessary to remove piston; usually from the bottom if a small size piston—as explained on page 646.

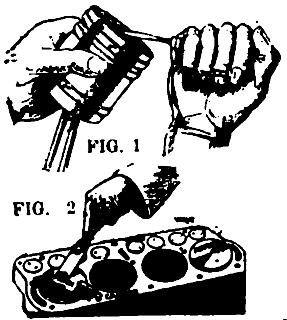


Fig. 2. Another method is to remove the cylinder head, if it is a detachable type, as on the Ford. Access can then be had to tops of pistons and walls of combustion chamber in the head.

Special Scraping Tools.

Scraping tools of special design (fig. 4), are necessary for scraping the inside of cylinder, combustion chamber and head of piston when cylinder head is not detachable and where pistons are not removed. The work can be done through the valve cap or plug holes.

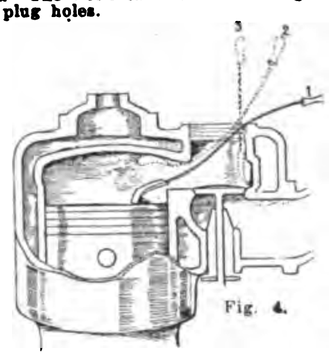

Fig. 4.

Tool No. 1 is for scraping the piston head; No. 2, for the cylinder head, as shown by dotted lines and No. 3, is for the cavities over and around the valves and such other surfaces that have considerable curvature.

Scraper No. 1, should be used first, and worked back and forth with considerable pressure across piston head until the scratching sensation disappears and tool seems to glide over the surface. Care should be taken, not to gouge grooves in the metal.

After scraping, blow out the free carbon, using a hand bellows, if compressed air is not available. Continue scraping until the blast of air does not blow out any more carbon dust and be sure to scrape the entire surface, for if jagged patches are left, they will become incandescent from the heat of explosion and cause pre-ignition.

It is important that none of the carbon gets into the cylinders, valves or other parts of the engine. Therefore be sure that valve is well seated in cylinder you are cleaning and be careful to blow out all carbon deposit thoroughly with an air blast.

Often, after as much carbon as possible has been taken from the cylinders, a half-tumblerful of kerosene poured into each cylinder and the air blast applied, will give good results. Another half-tumblerful of kerosene should be poured into the cylinders and the engine turned over a few times.

The oil reservoir should then be drained and cleaned thoroughly with a clean cloth previously soaked in gasoline, and fresh oil put into oil pan (after cleaning and using kerosene,) as kerosene will thin the oil and cause it to lose its lubricating qualities and is liable to cause the bearings to score or cut. If any of the kerosene is left in engine combustion chamber it will eventually work into crank-case.

It is customary to grind the valves after having scraped carbon, and after grinding, adjust valve clearance.

Oxygen Decarbonizing

Is a process of cleaning the carbon from inside of cylinder and head of piston, without removing the cylinder head, by means of an oxygen flame, per fig. 6.

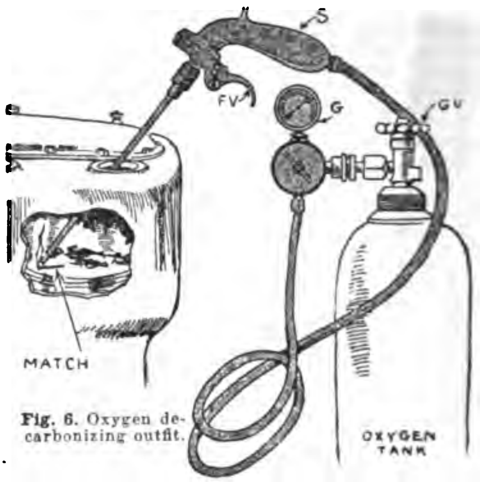

Fig. 6. Oxygen decarbonizing outfit.

The outfit (see also, page 727), **consists of an oxygen tank, at an initial pressure of about 1,800 lbs. per square inch, fitted with an adjustable reducing valve that brings the pressure down to 10 to 20 pounds, is employed, and the oxygen is applied through a torch or copper tube about 18" long, with a rather fine, flexible delivery jet, communicating with the reducing valve through a flexible tube and fitted with a trigger valve (FV). The delivery jet of the torch when entered through a valve plug orifice, can be manipulated to reach all parts of the combustion space, if slightly bent and cleverly turned and twisted by the operator.**

To Operate.

First: Turn off the gasoline at tank and let engine run until it uses up all gasoline in carburetor. If pan is greasy, remove it, to avoid the possibility of a fire.

Second: Remove hood and cover the air intake of carburetor with sheet asbestos so that no spark can drop into it.

Third: Remove large plugs into which spark plugs are screwed and clean cylinders, one at a time, being sure that the **piston is at its extreme height in each cylinder and that both intake and exhaust valves are closed** before starting to clean it.

Fourth: Start on valve chamber, first putting a few drops of kerosene oil or alcohol into it, ignite with a match or wax taper, insert tip of torch and direct a jet of oxygen against the carbonized surface. The jet of oxygen almost instantly consumes the carbon where it strikes, so move tip around until incandescence dies out, when it will be necessary to inject more kerosene or alcohol and repeat operation until chamber is thoroughly cleaned. When the burning starts the carbon will burn with a whitish flame and a shower of sparks will come out of the spark plug hole.

Next clean piston head. When it is impossible to see portions being cleaned, continue operation until the series of sparks stop blowing out, as sparks will cease as soon as carbon is entirely consumed.

To clean top and sides of cylinder, it is necessary to bend flexible copper tip of torch so as to direct the jet of oxygen upwards. To inject the kerosene or alcohol, use an oil gun or ordinary oil can with curved nozzle.

Alcohol leaves surfaces much lighter than kerosene, but when the oxygen strikes it there is quite a sharp report. **Kerosene is rather more quiet than alcohol.**

Some operators simply drop in a lighted match and then turn the jet upon it, but this method requires much more frequent igniting than when kerosene or alcohol is used. See "note" on page 625.

CHART NO. 249-A—Removing Carbon—different methods—see pages 720 and 727 for Oxy-acetylene Welding. For decarbonizing, only the oxygen tank is used.

Bad Effect of Carbon Deposit.

Carbon deposit will cause the **valves to leak** by the carbon gumming under the seat of the valve—thereby decreasing the power.

Carbon deposit cakes on the end of the piston and on the walls of the combustion chamber, which, when engine is hot will cause these small particles of carbon to become red hot and **cause premature ignition and result in pounding.** (see pages 233 and 635.)

Carbon deposit will also cause the spark plugs to become fouled, for if the oil you are using will cause carbon in one place it will accumulate on the spark plugs also. **In other words, carbon is a bad thing for an engine and ought to be removed.**

Soot or carbon deposit in an engine accumulates on the head of the piston and in the combustion chamber generally.

Indications of Carbon.

Carbonization of engine—general indications: If you should note that the engine, when fully supplied with water and oil and the spark lever in proper position, is overheating easily, has weak compression and developes a "knock" or "clank" when on a hard pull, there is probably a large deposit of carbon in the cylinder compression chambers. This may be due to the use of poor lubricating oil or incorrect adjustment of the carburetor. Even though it is not affected by these two conditions, a small residue of carbon will adhere to the interior of the compression chamber, and if left for a great length of time, will develop the trouble mentioned above. Of course the carbon sticking to the inside of a cylinder becomes red hot and **pre-ignites** the charge called **pre-ignition**—see pages 639 and 233. See page 202 for smoke indication of too much oil.

***Carbon Deposit Preventive.

Mix 85 per cent kerosene to 15 per cent denatured alcohol. Pour a few tablespoonfulls of this mixture into the cylinder of the engine through the relief cocks. To get the best results, the mixture should be poured in while the engine is still warm, after a run. Then close relief cocks, crank the engine with the switch off two or three times slowly; this will work the mixture thoroughly into the carbon. Then allow the engine to stand in this condition overnight. Next morning when starting there will be considerable smoke, but this will soon pass away. The exhaust "cut out" should be opened and the engine speeded up, so the dissolved carbon will pass out freely. This operation, if frequently used, will, to a considerable extent, keep the compression chambers and pistons clean. If there is considerable carbon already in cylinders before trying this, then it will be necessary to first have cylinders cleaned by scraping or by the oxygen decarbonizing process employed at some repair shop, because the carbon will probably be hard. After once cleaning the piston and by the use of this mixture and above all, the use of good oil, the cylinders should remain free from carbon. It is advisable to change old oil at this time, and put in a fresh supply.

Cleaning Carbon from Cylinders.

This is a job usually attended to when cylinders are re-ground. The frequency of the job depends upon the service, and quality and quantity of lubricating oil used. (see page 653.)

Methods of Cleaning.

There are five methods employed in cleaning carbon. The most effective being that one which removes the carbon most completely—probably by hand, but to remove piston is sometimes an expensive job and other recourses are resorted to as will be mentioned.

(1) One plan is to remove piston as per fig. 1, chart 249-A.
(2) To remove cylinder head as per fig. 2.
(3) To scrape with special scrapers as per fig. 4.
(4) To chemically clean and dissolve the carbon, per page 626.
(5) To clean by the oxygen decarbonizing process as per fig. 6, page 624. See also pages 726, 727.

This last mentioned method, is the most generally used and conceded to be one of the best.

Note: In using oxygen for carbon removal. The piston should be placed at the extreme top of the cylinder, as the intense heat tends to roughen the cylinder walls. The flame should not be directed to strike the threads of the spark plug hole, and see that the water system is kept full of water. The torch should be moved constantly to cover as large an area as possible.

Questions Sometimes Asked Relative To Oxygen Decarbonizing Outfits.

Q.—Where can oxy-decarbonizing outfits be secured?

A.—The Prest-o-lite Co., Indianapolis, Ind., make a good serviceable outfit, also the Turner Brass Works, Chicago; Imperial Brass Co., Chicago, see page 727.

Q.—Can the Prest-o-lite tank be used for this purpose?

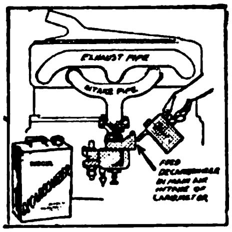
A.—The oxygen tank of their welding outfit can be used, but lighting gas cannot.

***It is important that kerosene is not mixed with the lubricating oil as it will lose its lubricating qualities. Crank-case should be wiped out before putting in fresh oil, see pages 201 and 205.

***A carbon preventive called "Woodworth Carbon-Clear" mnf'g'd by Woodworth Mnfg. Corp'n., Niagara Falls, N. Y. is mixed with the gasoline; one spoonful to five gallons. It is claimed this will prevent the formation of carbon.

Chemical Method for Removing Carbon.

There are several preparations on the market for this purpose. It comes in powder form which the makers claim, if mixed with the gasoline will prevent carbon formation.



Another, is known as a liquid decarbonizer. This chemical, the manufacturers claim will dissolve the carbon accumulation in the combustion chamber and on piston and will also loosen the rings if gummed and stuck to one side of piston.

In giving your engine the first dose and where carbon is well accumulated; start the engine and run until warm, shut engine down and pour the decarbonizer into each cylinder, say about ⅛ pint in each, where it can act on piston and rings. Also pour it over and around the valves. Leave the engine set over night, or at least three hours. After this time, start engine up and the carbon is supposed to pass off through exhaust in a similar manner as explained under "carbon deposit preventative," page 625.

After once cleaning in above manner, about once every two weeks, feed the decarbonizer to the engine by placing about ⅛ pint in an ordinary oil can and let it pass in the air intake of carburetor (see illustration), while engine is running, it will suck into engine and will be sufficient, to keep rings and valves clear and to keep carbon from forming.

Why an Engine Loses Power.

Four main causes. When an engine fails to develop its usual power the cause is frequently one of the following. (1) loss of compression; (2) deranged valve action; (3) faulty ignition; (4) improper carburetion mixture.

(1) ***Loss of compression** means more than simply failure to compress the charge a specific amount; it is a common name for a condition which not only means low initial compression and consequent weak explosion, but also that a smaller charge is taken into the cylinder, that a portion of the diminished charge escapes during the compression stroke without doing even a small amount of work, and that a part of the explosive force (the only source of power that an engine has), escapes through unauthorized channels—altogether a threefold loss.

Faulty compression comes from a variety of causes; cylinders may be worn, scored or cracked, pistons sometimes crack, rings become gummed, worn or broken, valves need grinding when pitted or warped, their stems are sometimes bent so that the valves cannot seat perfectly, or the stems and guides considerably worn. Valve stems become gummed and the springs sometimes weaken, so that a portion of the charge escapes before the valve shuts it in.

Leaks occur around spark plugs and valve caps, but are readily found by applying a little oil, while engine is running and noting if it bubbles.

(2) **Valve action** is disturbed by wear, usually the valve tappets were not giving sufficient opening, or set to give too much opening, or valves not properly timed. Valves not seating of course comes under loss of compression.

(3) **Faulty ignition** is occasioned by insufficient or unsuitable sparks, or a spark at the wrong time (see pages 307 and 308), which may result from imperfect setting of spark, weak battery, either primary or storage, or from demagnetization or some other trouble peculiar to the magneto. The timer should come under suspicion and be carefully examined for defects which lead to irregular action. Lack of synchronism means loss of power, and it is plain that missed explosions are fatal to efficiency. It is not always easy to detect missing or weak explosions and no doubt they pass unnoticed many times. If vibrator coils are used they probably need adjusting, or their contacts need dressing, see page 234.

(4) See page 168 for carburetion mixture.

Other Causes of Loss of Power.

Air leaks around inlet valve stems, making it impossible for even the best carburetor and the most careful regulation to supply a right mixture, as the leakage fluctuates and is greatest at the very time when the volume of gas used is the smallest, because there is stronger suction when the throttle is nearly closed, thereby completely upsetting right proportions at all throttle openings except the one adjusted, also air leaks around carburetor or intake connections. (see page 162).

Weak valve springs will also cause loss of power as explained on page 635.

The muffler may have become clogged by soot and charred oil, thus preventing a free exhaust and consequently a full charge, besides causing back pressure and undue heating. **Gasoline passages may have become clogged.**

The oiling system may fail to supply the needed amount of oil, or the oil used may not be of the former good quality.

Carbon may have accumulated in the cylinders; air valve in carburetor may be working badly because of dirt or wear.

Dragging brakes will consume a lot of power.

Sometimes the addition of a top, etc., is not duly allowed for, though every driver must have observed what a difference the weight of one passenger makes.

In conclusion it is suggested that **if a car does not run with its former power the cause is probably not due to any one thing,** but to a number, each contributing in proportion to its importance.

*The explosion pressure runs from three to four times that of compression. If the compression drops one-half, then the explosion pressure drops, but the loss is in more than direct proportion. It would seem that if the explosion pressure was one-half, the power developed would be one-half. But one must realize that it takes a certain amount of power merely to keep the engine moving. That is, to overcome the inertia and friction of the moving parts. This amount is constant. All power developed beyond this amount is available to run the car. If the compression and power drop to one-half, just as much power is required to run the engine, so that the available power drops in much greater degree.

The advantages of high compression are: greater engine efficiency at high speeds and greater economy in fuel. **The disadvantages,** are lack of flexibility at low speeds, greater strain on bearings and greater tendency to burn valves and plugs and also a tendency to over-heat.

A greater compression can be carried in an overhead valve engine regardless of stroke or bore, therefore larger valve openings are permissable.

Naturally this increases the heat, but as the valves are in the head, the discharge is rapid. The explosion pressure is generated directly above the piston center which receives no side thrusts.

The spark plugs in an "L" head type are usually over the inlet valves where the inrushing gas keeps them cool and where the fire is most certain—being in the most perfectly scavenged part of cylinder, i. e., the direct path of the fresh charge.

In the overhead type, on the contrary, they are exposed to the full heat of the explosion. In a high compression engine therefore only well-made plugs should be used. One method of protection is to surround the plug with a water jacket as much as possible.

Abnormal compression is prone to cause overheating. Results however can be obtained with high compression ratio, which cannot be approached with average compression.

If a high compression is desired in an L or T head engine, in order to take advantage of the high compression the cylinders must be designed with a sufficient long stroke, to enable the desired ratio to be obtained without raising the piston appreciably above the floor of the valve pockets, as at (L) in the illustration.

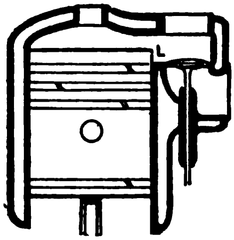


Fig. 1—This illustration shows type of piston referred to. It will be obvious that the explosion will develop in valve pocket (L) and part of its value lost when piston projects above top of cylinder to any great extent.

†Compression Average of Engines.

The usual compression ratio for touring car engines, is about 55 to 60 lbs. on 4 and 6 cyl. engines and 60 to 70 lbs. on 8 and 12 cyl. engines, per sq. inch, without the additional effects. This when running at average road speeds, probably increases. See also, page 535 and foot note page 640. Tendency is to decrease compression as the dia. of bore increases.

A six, eight or twelve cylinder engine, having a much more continuous torque than a single cylinder engine, will obviously stand a higher ratio of compression.

The maximum compression is determined when throttle is wide open and all pet cocks closed. For instance the compression in cylinder of a Packard should show 75 to 85 lbs. pressure at cranking speed with pet cocks closed and wide open throttle.

Compression at time of explosion at instant when piston is at top of stroke is very hard to determine. Factors which would have to be taken into consideration are: character of fuel, degree of mixture, speed of engine. In the average engine, pressure at explosion would probably be about 250 pounds. See page 536 for M. E. P. and page 535 for meaning of **compression pressure.**

Compression Effect and Cause.

The subject of compression is one of the most important subjects connected with a gasoline engine—**if an engine lacks power, nine times out of ten it will be traced to poor compression.**

The compression space in an engine is the space between the end of the piston and the top of the inside of the cylinder at at (L), fig. 1. In drawing in a charge of gas into the cylinder, the piston travels downward, but after drawing in the gas through the intake valve, the valve closes and the piston on its up stroke pushes the gas up into the head of the cylinder and **compresses it.** (see page 307.) If the valve leaks, or there is a leak otherwise, then the gas will not be compressed to as high a pressure as if there was no leak.

These joints must be tight at all times. For instance, if the cylinder head gaskets or the small gasket in the spark plug, or the spark plug itself is not tight, gas will leak out and cause loss of compression and lack of power.

There may be a leak in the gasket connecting the intake pipe. This is a very common cause for missing at low speeds, and is best detected by allowing the engine to run at the missing speed (see page 162 and chart 292). Take a squirt can full of gasoline and squirt around all the intake pipe joints. If you detect any difference whatsoever in the running of the engine, there is a leak. The remedy is obvious.

**When cylinders are not cast en-bloc (see page 81) care must be taken that gaskets are of exactly the same thickness, otherwise the cylinder with the thickest gasket, will be raised higher than the others and consequently have larger combustion space and as a result have lower compression. This in turn disturbs the running balance.

In two-cycle engines conditions would be even worse, for here we not only increase combustion space, and enlarge the lower space (which in 2 cycle engines is an important feature,) but we also change the port timing, as a little thought on this subject will prove.

*See page 307 and foot note bottom of page 626 and page 535 for "Compression."

**See page 640. †On engines using kerosene about 55 lbs. is the average. Note foot note, page 626 and page 535, about difference between "compression" and "explosion pressure." Also see foot note page 909 and pages 793, 817.

Asbestos gaskets when replaced are first coated with shellac or soaked in linseed oil. Copper gaskets are soft and give, therefore do not require this treatment.

When the gas is compressed to the highest point, then the spark ignites the compressed gas and forces the piston down with great force. **If the compression pressure is low the force** will be **less. If** the **compression** power is **high** the **force will** be **greater.**

***Leaks will affect the operation of the engine, in weakening the compression,** diluting the fresh charge by the air that enters, the escape of the pressure during the power stroke, and the igniting of the mixture in the inlet pipe. **Therefore the power of an engine depends on good compression,** and good compression must be maintained.

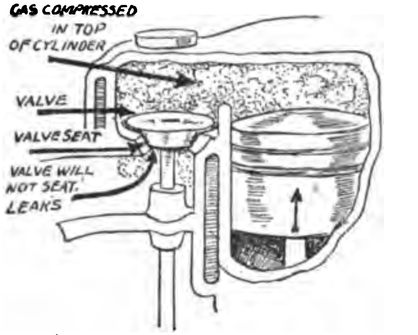

Fig. 2—If compression is poor, the probable cause; valves are leaking at the seat. (see also page 92.)

There are many places to look for compression leaks; through the valves not being set right or through the **valves leaking** at the seat, through the **valve caps** not being screwed down tight, through the **spark plugs, relief cocks and piston rings.** I have also known leaks to occur through a small sand hole in the end of the piston. See foot note, page 656, to test.

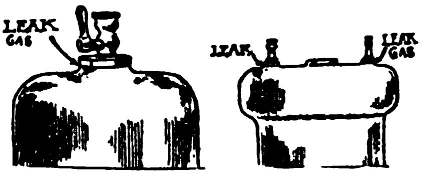

Fig. 3—Other causes of leaks may be in the spark plug, gasket or piston rings. (see also page 162)

The most frequent cause of leakage is from pitted valves (see page 630), which by not closing tightly, permit the pressure to escape. If the valves are in good condition, and the spark plugs and other openings in the cylinder head are tight, leaky piston rings may be causing the loss and should be examined.

The spark plug and the relief cock may be made tight by the use of copper-asbestos washers, or by a copper washer, that metal being soft enough to be forced into the rough places, (see chart 292.)

Leaky valves may be ground in as described under "valve grinding." (see page 630.)

Other Causes of Loss of Compression.

It is probable that the cylinder wall, cylinder head, or piston head is cracked. A **crack in the cylinder wall** will admit water to the cylinder from the water jacket. If a hole is suspected, a test can be made on the cylinder to see if there is a leak by putting a foot pump connection to the water jacket of the cylinder, fill water jacket with water and apply the air pressure and see if bubbles of water ooze through, inside of cylinder. If this is the case then these holes must be made tight.

If water is found in the crank case, it is evident that there is a leak through cylinder from water jacket. It is possible, sometimes, to stop these leaks with salammoniac. See "index" for this subject.

To detect a crack in the piston head, it must first be scraped clean of the carbon deposit and examined carefully.

Sometimes there will be a discharge back into the carburetor; this indicates a leaky intake valve, providing it is not first found to be in the fault of carburetor adjustment.

Sometimes a discharge in the muffler indicates a leaky exhaust valve, but not always. It will require an experienced ear to detect the difference from that of an unfired charge being exploded in the muffler, due to carburetor adjustment and that of a leaky exhaust valve.

When the piston rings have been cut and scratched by long use, or running without oil, the leak will be into the crank case, and when this part heats so that it is uncomfortable to touch, it is an indication that it exists. The only remedy is the reboring of the cylinders, and the fitting of new piston rings, or if not too badly scratched new piston rings may suffice. Piston rings must be handled carefully, for they are very brittle. To place new ones in position, see chart 261 and page 657.

When piston rings are not pinned in position, they may work around in their grooves so that their split ends are in line, and this will often give the compression an opportunity to escape. Therefore, see that the split ends are not in line. (see chart 261.)

Piston Rings Cause of Leaks.

If the piston rings are in good condition, they will be smooth and shiny, as will also be the cylinders walls. If the rings are dull and dirty in spots and streaks, it will indicate that the flame passes between them and the walls, leaving a sooty deposit.

Badly fitting piston rings may be caused by the rings sticking in their grooves, because of gummy deposit from the lubricat-

***At higher speeds of engine a slight compression leak is not so noticeable as at low engine speed.** If it is desirable to have engine throttle down to very slow speed then be sure that there are no compression leaks in any part of engine including rings, as one leaky cylinder will effect the others. See also, page 655.

ing oil; rings that are stuck in their grooves will not press against the cylinder walls and will cause loss of compression. Kerosene oil will cut this gum, and free the rings. If this is suspected, a little kerosene poured into the cylinder and distributed by cranking the engine will cure it.

Leaky gaskets cause loss of compression: On page 717 and page 162, the different places for gaskets are shown.

**Testing Compression.

The compression is much easier to test than the carburetor or ignition apparatus.

***To test the compression of the engine** one has but to crank it slowly (with switch off) and note the comparative resistance of each cylinder and the resistance of all in general. If the resistance of the compression of one or more cylinders is comparatively poor, under ordinary conditions the valves of those cylinders need grinding. If the resistance of all of the cylinders is not up to the regular standard, then, perhaps, all require regrinding.

A method of testing with a special gauge is shown in fig. 4.

Fig. 4—Testing with a compressometer: This is a special gauge designed for testing the comparative pressure of each cylinder.

It is attached to the engine cylinder by removing a spark plug and fitting compresso-meter instead. The engine should be turned over two or three times either with the self-starter or crank.

Compression of the cylinder to which the compressometer is attached is indicated on the instrument as the maximum hand (short one) remains at the highest point so indicated. Note the two hands; the short one remains fixed at the highest point reached during the test.

As you test each cylinder separately, enter the reading on a slip of paper, then compare the results. Those cylinders showing low compression are leaking and the cause should be found and remedied.

A cylinder with good compression cranks with a springy resistance. If it cranks very freely, it may be considered an evidence of poor compression and the cylinders should be tested for compression one at a time, as follows:

The compression relief cocks (if a six cylinder) on five of the cylinders, say Nos. 2, 3, 4, 5, and 6, should be opened and the compression of No. 1 noted when turning the engine over. Then close relief cock No. 2, open cock No. 1 and crank again to test No. 2 and so on until the six cylinders are tested.

A leak through one or more valves generally is accompanied by misfiring and loss of power. A slight leak through all of the valves is accompanied by loss of power, but often without misfiring.

Grinding the valves will probably remedy this, if the leak is not due to leaky piston rings. Sometimes leaky piston ring trouble can be remedied by first giving the engine the kerosene treatment and tightening up the spark plugs and valve caps.

To test for a leak at the valve cap, spark plug, and relief cock: Pour oil over the cap on top of the cylinder block and if bubbles occur when the piston is moving upward, it is an indication that there is a leak. It can be corrected by simply tightening the cap or it may be necessary to renew gasket. Pour water into valve cap to detect leak where spark plug or relief cock is screwed into it. Leaks very seldom occur here, but when they do, remedy by merely tightening up.

†**A compression leak between the piston and cylinder walls** is rather difficult to test —probably the best way, is to first correct valve compression leaks and valve cap leaks, then if the compression is still poor, then the leak must be between the piston and the cylinder wall. This can be corrected by taking out piston and putting in new rings.

The owner of a car, however, will very seldom be troubled by a compression leak between the piston and the cylinder wall as the rings are held in close contact to the cylinder walls by spring tension. This means that when free they are a little larger than the bore of the cylinder and they are sprung into place in the grooves of the piston and inserted into the cylinder, wear is taken up and contact surface perfected by the action of the spring tension.

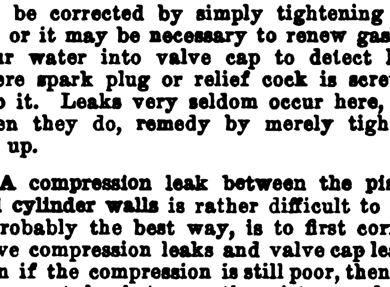

Fig. 5—To test for intake valve and piston ring leaks—a suggestion.

To test for inlet valve leak: Place a hose over the carburetor air intake as per fig. 5. With throttle wide open, have some one crank engine with switch off. Place hose to ear; if a hissing sound is heard when piston is on compression stroke, the inlet valve is leaking and needs grinding.

Crank as before; if a hissing is heard, the pressure is escaping past the piston ring, down wall of cylinder into crank case. In this case new rings are required or maybe kerosene treatment will suffice.

*See page 627; "maximum compression determined with throttle wide open."

**If after these tests compression is not restored, the trouble is a serious one, requiring removal of cylinders. The piston rings may be broken, scored, or badly worn, or the cylinders may be scored also. Such troubles require a well-equipped repair shop, as new rings must be fitted and the cylinders reground. Keep in touch, so to speak, with the compression in your engine if you wish to obtain best results. †Piston sometimes has a flaw in casting and a small hole will permit loss of compression—see page 656, foot note, how to test. A circular describing a new principle of testing engine knocks by means of an air compressor can be secured of A. L. Dyke, Granite Bldg., St. Louis, Mo.

When spark plugs are constantly oily and fouling, this is an indication of oil passing from crank case past a loose ring.

It is also indicated by excessive lubricating oil smoke (blue) passing out exhaust, the oil works up past rings.

Spark Plugs Indicate Valve Condition.

The condition of spark plugs will sometimes indicate condition of valves. If the end of the spark plug is oily it indicates too much lubricating oil or leaky piston rings. If black soft soot, like that which accumulates in a lamp chimney, this indicates that too much gasoline is being fed to the cylinder through intake, causing too rich a mixture. This may come from improper carburetor adjustment or an air leak in intake manifold. If the end of the plugs are oily and sooty, this would indicate that the valves leak, as this permits burnt gases being drawn into the mixture, which would result in poor combustion and lack of pressure in cylinder, also permitting oil to pass and foul the plug.

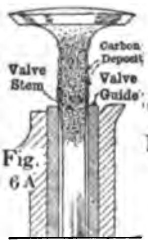
Prussian Blue for a Valve Test.

To test valve head seat: Buy a ten cent tube of Prussian blue at any paint store. Loosen the valve spring, and **blue the face of the valve** and then turn it one quarter around in the valve seat. If the seat shows a clear clean line of blue, you have a perfect fitting valve. If there are points where the blue does not touch, you have worn or warped valve or a faulty seat.

To test valve seat: Reverse the operation and place the Prussian **blue on the valve seat,** repeating the one quarter turn. If there are points where the blue does not touch, the valve and seat both require attention.

Valve Troubles.

To determine if valves need grinding or reseating: Valve grinding will ordinarily remove small pits, but if badly pitted or if valve head is warped (caused by excessive heating), out of line with its seat, or if shoulders appear on the valve face or valve seat, they should first be re-seated with a special re-seating tool and then ground to a smooth surface.



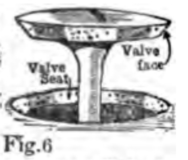


Fig. 6—Note the black spots on valve face and valve seat. This permits the escape of gas. If ground or reseated the spots will be removed and valve will seat tight, if pitting is not too deep and valve spring not too weak.

Fig. 6A—Exhaust valve stems often become carbon coated and when engine is driven at high speeds the temperature increases, causing expansion, and the result is the valve will be given a taper effect which will not permit valve to seat properly. Often times this is the cause of a leaky valve and stem should be cleaned thoroughly and sufficient clearance allowed between valve stem and valve guide.

Refitting New Valves.

When valve stems become badly worn, it is almost a certainty that the guide or hole through which the stem passes is also worn out of round. The cheapest and best way to remedy this, is to ream out the guide hole and install another valve with an "oversize" stem, as shown in fig. 21.

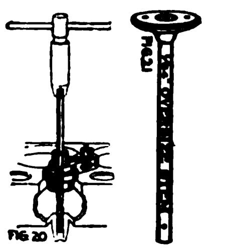

Fig. 20 — Guide reamer for reaming oversize valve guide.

Fig. 21 — Valve with oversize stem.

The reamer set (fig. 20), includes a case hardened guide, which fits in the valve cap recess and insures that the finished hole will be true and in perfect alignment.

The over-size valve stems vary in size by 64ths of an inch and usually 1-64 larger is all that will be found necessary, unless too badly worn, see page 609, 791.

Grinding Valves.

Valve grinding is necessary when either the inlet or exhaust valves leak. The exhaust valve has a tendency to leak more than an inlet valve because it is more exposed to the heat.

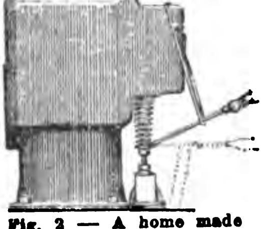

Fig. 2 — A home made valve spring lifter.

To test if valves need grinding, see above "Prussian blue test." Also try the compression. Weak compression usually results from leaky valves also leaky rings, therefore be sure it is the valve and not the rings.

***To grind valves is not a difficult process.** It is merely a slow and pains taking job, and is better done the more patient and untiring the operator is. Don't let any one tell you that it requires an expert or a mechanic, as such is not the case.

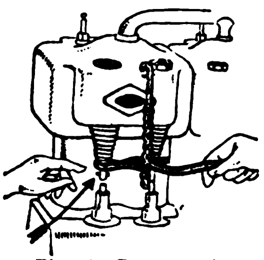

Fig. 1—Remove pin in end of valve stem. A spring lifter will make this easy.

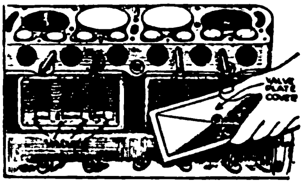
First remove the intake pipe (if it is in the way). **Remove the valve cap.** Use some

*If the repairman finds difficulty in grinding some of the valves, owing to the fact that the abrasive will cut the surface very slowly, it is because that particular engine has a very hard alloy steel Tungsten valve. When fitting new valves call for Tungsten metal valves. However, good valves are also made with cast iron heads welded to steel stems.

Clover Grinding Compound for grinding valves, grinding pistons into cylinders, lapping out cylinders, grinding crankshafts into bearings, polishing crankshafts, etc., is manufactured by Clover Mfg. C., Norwalk, Conn. This concern issues a very instructive free Bulletin on valve grinding.

form of spring holder so that the tension of the spring is relieved while the key is taken



Valve cover removed exposing the valve springs.

out from under the spring. These springs are very stiff and will require a special spring lifter of some form which can be secured at any supply house or you can make a serviceable tool, of a ½ inch iron bar, about 18 inches long and split at one end, as per fig. 2, (page 630.) **After the key is removed, then the valve is lifted out of its seat.** (see also page 92).

Second, place some valve grinding compound on the face of the valve. The usual proceedure is to first apply a coat of oil on the seat, then distribute it with the tip of the finger; then dip the finger

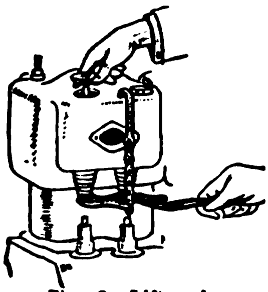


Fig. 3—Lift valve out of cylinder.

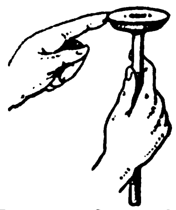

Fig. 4 — Smear the valve grinding compound around edge of valve.

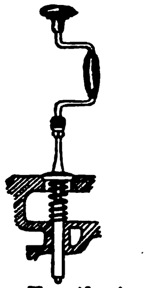
into the emery (flour of emery) and apply this to the seat. Put on an even coat and don't plaster it all around the surrounding metal parts. Take your time.

**There are special prepared grinding compounds which can be secured at supply houses. It comes in three grades No. 1, No. 2, and No. 3. The first is coarse and cuts heavily; the second does not cut so much, and the third polishes.

Third, place valve back into seat; then use a screwdriver or a brace with a screwdriver bit, placing the point in the recess, with which most valves are provided.



There are various ways to grind valves; with a breast drill or brace and screw driver bit or by hand, with a regular screw driver, or by machinery, see also pages 632, 633, 616, 615 and 592. There are numerous valve grinding tools on the market.

A spring should be placed under valve as shown. This will allow the valve to raise from its seat occasionally. Place a cloth in the opening to cylinder to prevent the grinding powder and dirt getting in. And be sure and take it out when through.

Fourth, turn the valve half a revolution back and forth in its seat, and occasionally lift from its seat and shift around. Don't turn round and round.

When the pits on the valve are almost removed, continue the operation with flour of emery of a finer grade instead of the coarse grade; remove the valve oftener, applying more oil and less emery each time, until a good seat is obtained all around; then finish up by polishing the seats with oil. Kerosene is most effectively used in finishing, and the smoother the finish obtained the less chance for a leak. Be sure valve stems are free in the guides.

Remove valve and clean both head and seat with kerosene and don't overlook cleaning the valve stem.

If a polished seat is desired, finish as follows: When the valve is ground to a dull, smooth surface, remove and clean valve face thoroughly. Do not clean valve seat, but leave upon it the compound which remains from the last grinding. Replace valve and give twenty or thirty turns. Remove again, clean valve, but not seat as before. Replace valve and repeat until the desired polish is obtained. The polished seat may look somewhat better, but the dull smooth seat gives much better results, as has been proven by test.

When grinding valves, a pressure of about 3½ lbs. is sufficient. More pressure than this will cause grinding compound to cut rings in the valve or seat.

A valve that is properly seated will bounce back when dropped into its seat. If it stops with a dull thud, either the grinding is not perfect or the valve stem is bent.

After grinding valves adjust the valve clearance as per pages 94 and 634. It is advisable however, to allow the valve tappets to run loose for a period of several days before adjusting them to the minimum amount of clearance or space.

*Grinding Cage Type Valves.

The above instructions are for grinding the poppet type of valve in an "L" or "T" type of cylinder. If the valve is of the, "cage" type, used in some of the I head cylinders, then the cage must be removed as shown in illustration, fig. 2, chart 250. The cage is placed in a countersunk hole in the bench, with a spring under the valve to raise it. In fact it is a good idea to place springs under all types of valves when grinding as shown at top of this page—right hand illustration.

If the spring is tied as shown in fig. 3, chart 250, it will be easier to replace.

To tell when valve is ground or has a perfect seat, see page 630; "Prussian blue test." Another method is to mark the valve face with a pencil, as shown in fig. 3, chart 250.

Reseating Valves

Is explained in chart 250. Ordinarily valve grinding will answer, but if valves are badly pitted, warped or a shoulder appears, then it needs refacing and reseating.

Q.—I have a Mitchell 6-50-1914 model. Valve seats have been ground till the valves drop a ¼ inch into seat and the valve is not level with the combustion chamber till the piston has descended ½ of suction stroke. Valves are 2¼ ins. Cylinder bore 4¼, stroke 6 ins. Would it do to reseat with a 2½ inch reseater and use 2½ inch valves?

A.—Your suggestion to use 2½ inch valves is a good one. Leave the seat narrow so it will last longer. 1-16 to ⅛ inch is wide enough for the seat in the cylinder. You can get the valve blanks at the St. Louis Machinist Supply Company, St. Louis, Mo., or most any auto supply house.

*To grind overhead type valves with valve seat in cylinder head, see page 636. To grind overhead type valves where they are operated by overhead cam-shaft, see page 913. **See foot note, page 630.

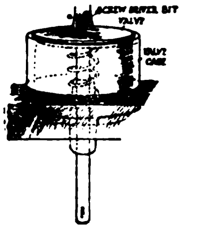


Fig. 2.—Cage type of valve. To grind this type, remove cage and valve and grind in same manner as the poppet valve, see fig. 8, page 90, fig. 4, page 94.

Overhead operated valves on an engine not equipped with removable heads are of the cage type (see pages 90 and 91). They are also of the "valve in head" type, see pages 90 and 109.

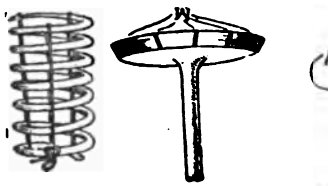

Fig. 3.—To test the finish of a valve face after grinding: mark it with a lead pencil as shown about ½ in. apart or less; after putting valve in place and oscillated about ¼ turn, if all marks are erased the job is satisfactory. (The marks on valve "W" are the pencil marks to be erased.) The Prussian blue test, is also a good method for testing, see page 630.

Tie the valve spring before trying to replace it. A simple method is to compress a valve spring between the jaws of a vise. Whilst compressed it is tied up with a loop of wire or string in two or three places. When the spring is thus tied up under tension its replacement is easy. This is not necessary if a valve spring lifter is at hand, see page 630.

Fig. 5.—Illustrating the method for **refacing** a valve with a Healy refacing tool.

Refacing Valve.

The subject of valve grinding is treated on page 630. Where valves are badly pitted or warped, or where shoulders appear, this will then require more than mere grinding. A special tool is therefore required to reface the valve and for reseating the valve seat.

The dresser head for refacing the valve and a reseater for reaming out the valve seats—both being adjustable for different size valves, is shown in figs. 5 and 6.

Refacing a valve is shown in fig. 5. This method was the approved method when valve stems were made of steel and had a cast iron valve head electrically welded to stem, but now, many manufacturers are using hard tungsten steel valves, therefore the usual way a tungsten valve is refaced is by putting it in a lathe and emerying it down.

The McCullough valve refacer however, will save the necessity of doing the work in the lathe and will accurately reface any valve, tungsten or other kinds of metal valves in one or two minutes time, see fig. 7.

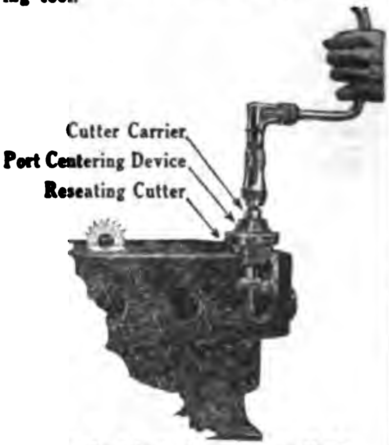

Fig. 6—Illustrating the method of **truing up a valve seat and reaming a worn valve stem guide.**

Reseating Valve Seats.

Truing up a valve seat in the cylinder is usually done with standard sizes of **valve reseating cutter**, one type is shown in fig. 6.

When reseating valve seats the novice must be careful to not cut too deep into the seat and thereby lower the valve stem. In fact, it is advisable to **adjust the valve clearance after either grinding or reseating valves.** After reseating, always grind the valve in order to make a good tight seating. (see fig. 8, of an improved method of reseating valves.)

A perfect seat is assured when a white line extends clear around both the valve and the seat, when giving the prussian blue test. The width of the line is immaterial, but the narrower the line, the better the compression will be because there is less area for the pressure of the valve spring to act on. However, it is not well to have the ring less than ⅛ inch wide.

A valve seat should have a bevel of not less than 45 degrees. Less than this the valve will stick. A good angle is 60 degrees.

It will be noticed that some valve stems seem to wear very much on one side. This may be caused by one or more of three things, viz: the hole is not concentric with the valve seat—which can be remedied by reseating in a radial drill press; the top of the valve lifter is not at right angles with the valve stem, wedging it off to one side, or the same may be true of the valve cap on the stem of the valve. These two latter troubles can be remedied by the judicious use of the file.

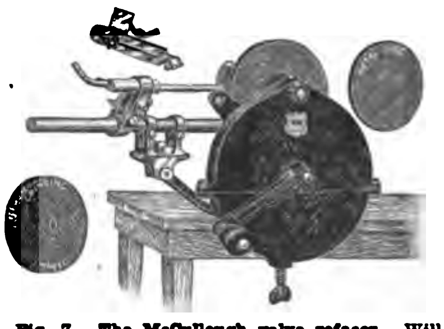

Fig. 7.—The McCullough valve refacer. Will reface hard tungsten valves and other kinds. Cutting surface is carborundum cloth, glued to steel discs, an emery wheel is furnished with the outfit, also a valve reseating tool as shown in fig. 8, (write B. L. Fry Mfg. Co., St. Louis Mo. for descriptive folder).

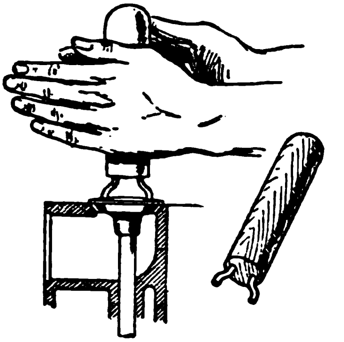
Reaming Guides.

Worn valve stem guides allow air to be drawn through, which causes an imperfect mixture. In this instance the valve stem guide ought to be reamed out and an over size valve put into its place, (see fig. 21, pages 630 and 609.)

Fig. 8.—McCullough valve reseating tool consists of a carborundum cloth cone held to the face of the valve as shown. The valve is used just the same as a reamer. The cloth cutting the seat in the cylinder exactly the same bevel as that of the valve face. No reamers are required. There is nothing to replace but the carborundum cloth. Emery cloth or sand paper will do quite as well but will not last as long.

100 or more valves can be refaced with one cloth disc, fig. 7. and 10 or 12 valves can be refaced with one cloth cone. Mfg'd by B. L. Fry Mfg. Co., St. Louis, Mo.

CHART NO. 250—Refacing Valve Heads, Reseating Valve Seats and Reaming Valve Stem Guides.

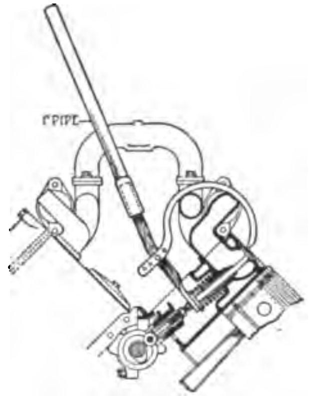


EMERGENCY VALVE TOOL

An emergency tool for grinding Ford valves may be made from an 8 in. length of broom handle and two nails. The two nails are driven into the sawed off end of the handle, until only about one inch of the nail is left. The heads of the nails are then filed off and bent until they will fit into the drilled holes in the valve top.—

VALVE-GRINDING TOOL

A simple tool for facilitating valve grinding is illustrated. The body of the tool is made of 1¼-in. flat stock, 3/16 in. thick and about 6 in. long. The upper end is forged round and fitted with bit-stock hand rest, the lower end carrying the jaws for engaging the valve. A short length of round stock riveted on provides a convenient handle. A similar tool with a screwdriver point may be made for valves with a slotted head.—



COLE 8-VALVE TOOL

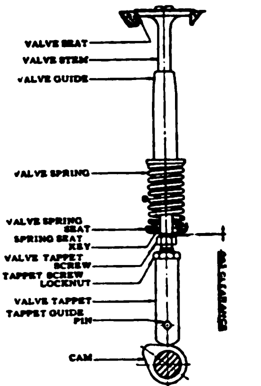


Fig. 20—A valve and its parts. Ford valve has no tappet adjustment.

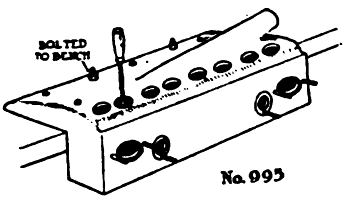
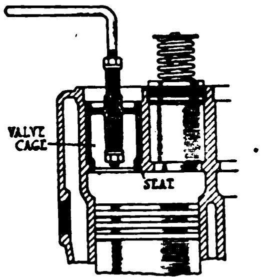


MAXWELL VALVE GRINDING

The cylinder head of the 1914 and 1915 Maxwell should not be removed unless absolutely necessary, but when removed valve grinding is facilitated by bolting the head to the bench in the manner shown Not only are the valves more accessible, but the light at the bench is usually better than at the repair stand.—



GRINDING BUICK VALVES

A simple way of grinding a Buick valve cage to a perfect seat is shown herewith. Through the center of the cage insert a round iron rod which has been threaded for a nut at the two places shown. Then tighten the nuts. With the rod as a handle, the cage can be rotated easily.—

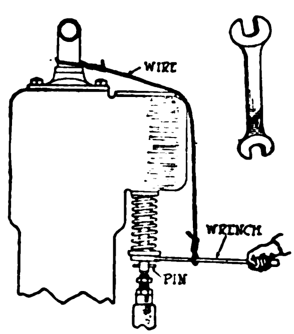


Fig. 27—Another method of releasing spring tension to remove pin or washer on end of valve with use of a flat wrench.

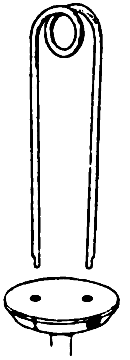

VALVE LIFTER

Valves designed to be ground by means of a spanner wrench may be lifted from their seats by means of a valve lifter made from a spring steel rod. A piece of 3/16-in. round rod, about 14 in. long, is heated and bent in the form illustrated, after which the coil is spring tempered. The points are filed down until they are a snug fit in the holes in the valve top. Valves may be ground and readily lifted out for inspection by means of this device.—

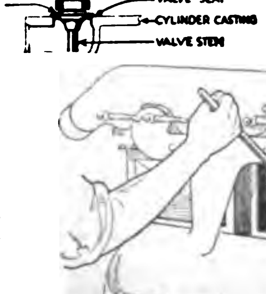

Fig. 60—Ford valve grinding tool.

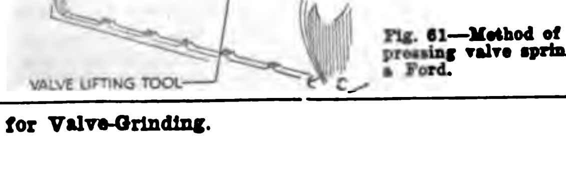

Fig. 61—Method of compressing valve spring on a Ford.

CHART NO. 250-A—Handy Devices for Valve-Grinding.
(Motor World.)

Noisy Valves—figs. 2 and 3.

Difficulty is frequently experienced in locating noises in and about the engine, probably because there are so many of them that it is difficult to determine where to begin.

Attention to the valve-stem clearance usually becomes necessary when the valve becomes lowered as the result of repeated grindings.

The best way, perhaps, is to go about it in a systematic manner, starting with the most likely sources, as in the valve lifts.

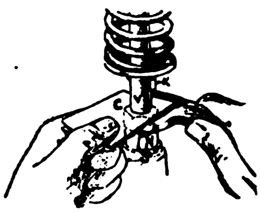

Fig. 1—Valve Adjusting.

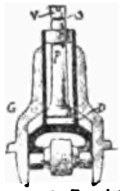

Fig. 2—V—valve. S—space between valve and plunger. P—plunger

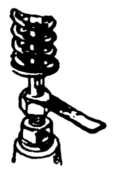

Fig. 3—Tool inserted between valve and plunger to find if the noise ceases.

Referring to the accompanying figure; place a thin piece of metal under a suspected valve stem, as shown in fig. 3, and when the noisy one is found the insertion of the tool will cause the clicking to cease abruptly and will remain quiet until tool is removed.

The repairman can generally find a tappet that is badly out of adjustment in a very short time by simply working the tappets of each cylinder up against the valve stems and down again, with his fingers, while the pistons of the respective cylinders are on their compression strokes.

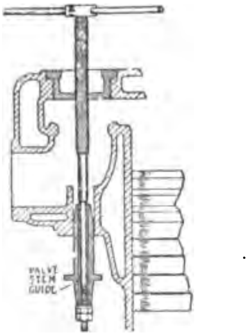
Proper adjustment of the valve tappets will help in reducing the noise which invariably occurs when there is any wear.

*The proper space between the ends of the push rods and valve stems is as explained on pages 635, 94, 542 and pages 95 and 110. The smaller the space, the less noise; but sufficient space must be allowed due to expansion when the engine is warm and irregularities in shape of cam or roller.

Sometimes one or two tappets may need adjustment, while others may be in good shape; in such cases there will be a clicking sound at regular intervals.

Valve Adjusting—fig. 1.

In the absence of a suitable gauge for regulating valve space, many repairmen use a piece of paper as shown at (C) fig. 1. It is folded once and slipped between the ends of the stem and tappet, the lock nut N is loosened, and the stud S in screwed up or outward until it just begins to pinch the paper and prevents it from sliding about as readily as at first. The paper is then removed and the lock nut is tightened.



When both the inlet and exhaust valves have been adjusted in this manner, each one should be individually tested with a single thickness (a thickness gauge is best—see page 699, see also, page 542 for the adjustment or gap necessary for leading engines) to see if the valves remain tightly closed throughout their required period. This is best done by sliding the single thickness of paper back and forth as the engine is being turned slowly from the closing to the opening points of each valve. The marks on the fly wheel may be used to advantage in this operation if accessible, but they are not necessary. One can slide the paper under a stem and turn the engine over until the paper is seized, indicating valve opening, then a little farther until it is free again, which marks the closing of the valve; now, by turning still farther and continually sliding the paper about, if it is not seized before the regular time for the valve to open (according to either the position of the piston or crank handle), the adjustment is about right, but if the paper is prematurely seized the space is insufficient. The valve in each cylinder should be adjusted in the same manner.*

Valve Guides.

Fig. 7—Replacing valve guides: The valve guides of T- or L-head motors may be driven from the cylinder casting from above. The fitting of new guides must be done with more care, however, as a slight distortion of the guide will cause the valve to stick. The puller illustrated is ideal for this work, as it applies a steady, even pull to the guide in a manner that cannot spring it out of shape. An old cylinder cap is drilled and tapped to carry the threaded rod, which may be made on the lathe in a few minutes.

Many valve guides are not bushed but are simply drilled passages in metal of engine, as per fig 7, page 94.

In this construction, the guide is reamed larger and an oversize valve put in as per pages 630 and 609. Where separate bushings are used as in the illustration above, the old guide is driven out from the top and a new bushing drawn in from bottom as shown.

On older model (Dodge cars) the valve guide was integral with cylinder and a 35/64" drill bores out worn guide. Then a .556" reamer is run through. Then a finishing cut taken with a 9/16" reamer. **Average clearance** is .002 to .003.

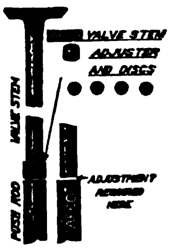


Fig. 9.

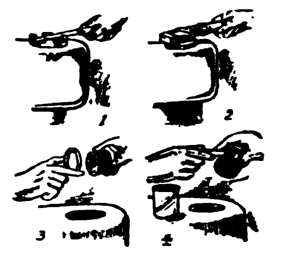

Fig. 10.

Fig. 9—Valve adjusters: where no provision is made for adjusting the valve clearance, **adjusters** made of steel lined with fibre (to reduce noise) can be had of supply houses.

Fig. 10—Valve caps—are placed over each valve and are finely threaded and provided with copper gasket (3). The threads should be coated with graphite when removed—else one will have difficulty in removing. (1) shows a castellated type which sometimes is sunk into head of cylinder and requires a special tool to remove.

CHART NO. 251—Adjusting Valve Clearance. Replacing Valve Guides. Removing Valve Caps— also see pages 95 and 110; charts 228 and 284.

***On some engines the exhaust valve is given slightly more clearance than inlet valve, see page 542.**

Sticking valve is sometimes caused by worn valve guide, causing valve stem to stick at top and bottom of guide, with result that air is drawn into cylinder causing missing. If an oversize valve stem cannot be secured, then bush the guide and ream out the hole to a true fit for valve stem and then grind the valve.

‡Adjusting The Clearance of Valves and Tappets.

Adjustable valve clearance is where there is a valve tappet adjusting screw, per fig. 5, page 94. On the Ford, there is no adjustment, therefore new push rods (tappets) must be installed—see fig. 36, page 791, also page 785.

Valve clearance. On pages 94 and 634 the average valve clearance adjustment, when engine is cold is given. There is no set and fast rule however, unless the manufacturer gives a fixed clearance as per page 542. It is clear to see that a valve with a stem 12 inches long is going to expand more than a 6 inch valve stem. Furthermore an engine cooler than another, the valve stem will not expand as much. Therefore a good plan in absence of a set clearance is to give .001" to .002" clearance when engine is fully heated up.

Truck and tractor engines are given slightly more clearance than engines on pleasure cars.

The result of improper valve clearance will cause lack of power as explained on page 95 and per pages 96, 63.

To find which valve is noisy (clicking noise) fully explained in chart 251 and 254. Another method is shown in fig. 2.

To test: Let the engine run so that the noise is heard and then grip each valve spring firmly and pull it up with the hand against spring tension, as shown (fig. 2), so that the valve is not active. This is equivalent to running the engine with seven valves (if a four cylinder engine). Each valve should be lifted in this way and when the noise ceases, the noisy valve is the one which is being held. (also see page 638).

Fig 2

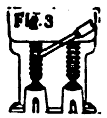
When adjusting valve clearance, remember that if no space at all is left between the valve and plunger, then the valve will not seat properly; therefore, it is important to get the distance exact.

Valve Springs.

If the springs of the exhaust valves become weak from use or heat, the pistons will draw burnt gases into the cylinders, past the valves with the incoming gasoline charge, giving an improper mixture. The valve springs should be tested when overhauling to see if they are full strength, see fig. 2, page 742. The average strength of a valve spring is about 30 pounds, but varies. Exhaust valve spring is stronger than inlet spring and at high engine speed exhaust valves nearly always permit some leakage. See foot note, page 628.

Valve springs that are too stiff are to be avoided because they may close the valves with so much force as to break the stems at the key, or the heads from the stems, and it is a certainty that the seats will be pounded out of shape, even if the valves do manage to stand the constant hammering action. **An excessively** stiff spring consumes power which might be used to a better advantage and there also is considerable noise.

To increase the tension; stretch the spring **a mere trifle by slightly** opening up the coils with a screwdriver (fig. 3), or by securing one end coil of the spring in a vise and tying a cord or the like onto the other end so as to get a grip, and then stretching it a little in the ordinary way.



Another way to increase the tension is to place a couple of washers under the lower end of the spring.

To test for a weak exhaust spring, insert a screw driver between the coils, thereby increasing the tension. If missing stops then remove spring and stretch it about an inch or put in a new one.

The reason of missing of explosion from a weak exhaust spring is, that when the throttle is closed, the piston cannot get much charge, and consequently it sucks the exhaust valve open and draws back some of the burned gases, which spoils the small charge in the cylinder, causing miss fire.

A weak inlet valve spring also makes itself evident by the mixture back-firing into the carburetor. Springs too weak to hold the valves on the cams will also produce clattering noises owing to belated seating of the valves.*

**Knocks.

Knocks are usually caused by the following parts being loose or worn:—

(1) Lower connecting rod bearings;
(2) Upper connecting rod bearing or wrist pin;
(3) Main crank shaft bearings;
(4) A loose piston;
(5) Timing gears;
(6) Cam shaft;
(7) Fly wheel;
(8) Carburetion not right;
(9) Running too far advanced on the spark;
(10) Worn valve stems;
(11) Pre-ignition;
(12) Badly worn or broken rings;
(13) Piston striking some projecting point.

Locating Knocks.

Minor causes: Before making tests, first determine if the cause of the knock is not due to the minor causes, which are easy to locate:—

(1) If cylinder is free from carbon and knock is not caused by pre-ignition (see pages 233 and 639).
(2) If knock is due to running with spark lever too far advanced, (see page 68).
(3) If carburetion is properly adjusted.
(4) If valve clearance is correct.

*Squeaks from exhaust valves may sometimes be stopped by dropping a small quantity of powdered graphite down the guides. If the valve tappets are noisy and no adjustment is provided, a great improvement can be effected by having steel caps with insert fitted. The smallest amount of clearance between the stem and tappet should be allowed. (see fig. 9, page 634 and 791.)

Valve guides which are worn will often cause missing or uneven running. If worn bad they must be reamed out and a bushing fitted the correct size, see fig. 6, page 632.

**See also, page 790. ‡See also, pages 791, 785, 542.

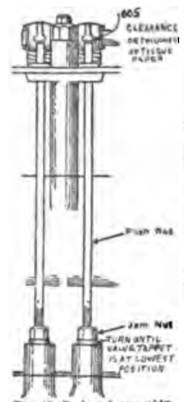


Fig. 13—Push rod assembly.

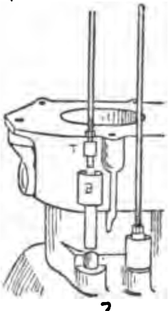

Fig. 14—Push rod and plunger removed.

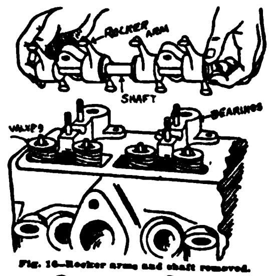

Fig. 16—Rocker arms and shaft removed.

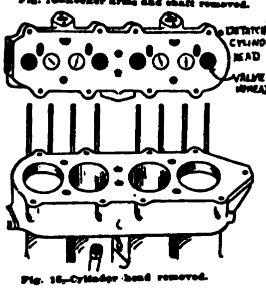

Fig. 15—Cylinder head removed.

Fig. 17—Removing valve springs.

Removing cylinder head rocker-arm and shaft: Disconnect upper radiator hose connection. Remove each of the bolts holding cylinder head to cylinder casting and lift the head off. The valves, rocker arms and bearings, being attached to head, will remain with it. Now remove the rocker arms and shafts as shown in fig. 16. Before removing, bearing caps should be marked with a center punch so that they will not become mixed when replacing.

Before replacing valves it is a good plan to scrape off all carbon deposit from combustion chamber and piston. Also examine copper asbestos gasket before replacing cylinder head. If not perfect, a new gasket should be used.

When replacing cylinder head bolts turn each one until head just touches cyl. head—then tighten each one evenly—a little at the time—none should be drawn tight until all are set snug. (see fig. 10, chart 259-A.)

Valve adjusting: To determine the proper valve clearance, crank engine by hand, turning until valve tappet has reached its lowest position.

The space between top of push rod and rocker arm should be about 0.005 inch, or thickness of ordinary sheet of tissue paper. If more, loosen jam nut and turn push rod until proper clearance is had, after which tighten jam nut.

The necessity of valve adjusting will show itself by excessive clicking of tappets and by poor running of engine.

Fig. 14 shows one of the push rod plungers removed for inspection or replacement. The pressed metal guide is fitted into a slot cut in the top of the push rod plunger, and can be removed and new rod installed if needed.

Fig. 18—Grinding valves.

Removing valve: Remove the small wire holding the valve spring cap pin in place. With a screw driver and your fingers press down upon the valve spring cap until spring has been compressed enough to admit pulling out the pin (fig. 17). Remove each valve separately, using care not to mix them in any way, as they must go back into the same valve holes.

Grinding: Secure a light coil spring and place it around the valve stem before replacing it for grinding. Smear the compound thinly on the beveled edge of the valve head and on the seat in the cylinder head. Place valve in the up-turned cylinder head and grind as shown in fig. 18.

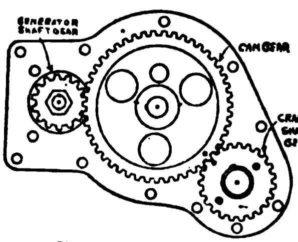

Fig. 21—Timing gear markings.

Valve timing: After having assembled the engine, with the exception of the cam shaft gear, insert the starting crank and turn until the piston in cylinder No. 1 is at its uppermost position.

By removing the spark plug in that cylinder a screw driver or rod can be inserted (fig. 19) and the position of the piston at its farthest upward movement can be determined. This is called the top center position of pistons 1 and 4.

Rotate the cam shaft so that the push rod operating No. 1 intake valve lightly touches the rocker arm. The opposite end of the rocker arm should be against the valve stem. The cam shaft gear then can be installed and properly secured.

The exhaust valve should be set up in the same way, that is, it should close at the same time that the intake valve begins to open. As the cams are integral the opening and closing of the valves on cylinders 2, 3 and 4 will come at the proper time, so it is only necessary after having secured the settings for cylinder No. 1 to adjust the push rods for proper clearance.

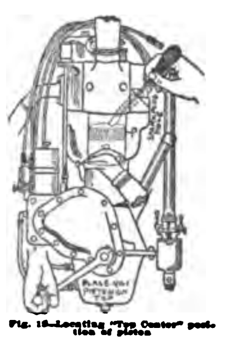

Fig. 19—Locating "Top Center" position of piston.

Fig. 21—Timing gears: These are housed in an oil-tight compartment at the forward end of the engine. They are the **crank shaft gear, cam shaft gear and generator shaft gear.** They are lubricated by the engine. Should it be necessary to remove them, care should be exercised in replacing to see that the marks on the rims of the gears match, as shown in fig. 21. Generator gear has no marks, as it is immaterial where meshed.

Valve timing in degrees; the intake valve begins to open and the exhaust valve is fully seated, when the piston has traveled 1/16 inch or 16° below top center. Inlet closes 52° after bottom and exhaust opens 40° before bottom.

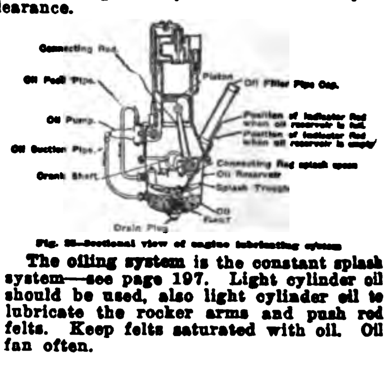

Fig. 22—Sectional view of engine lubricating system.

The oiling system is the constant splash system—see page 197. Light cylinder oil should be used, also light cylinder oil to lubricate the rocker arms and push rod felts. Keep felts saturated with oil. Oil fan often.

CHART NO. 252—Example of Valve Grinding of Overhead Valves in a Detachable Cylinder Head. Adjusting Push Rods. Valve Timing—(Chevrolet "490" as an example) see chart 179, for Timing the Ignition of Chevrolet and page 496 for Spark and Throttle control.

Chart 253 omitted (error in numbering).

After determining that the above is not the cause, then test from the outside of the engine with a sounding bar, so that the location of the knock will be determined, or at least some where near to it.

It is particularly important to learn at just what point in the engine the trouble exists, and what the cause is likely to be. With this information to start with no unnecessary parts need be removed, and much time will be saved. Aside from this, it is well known that an engine is always marred more or less by tearing down and this unnecessary expense should be avoided as much as possible.

We have often seen several good auto mechanics stand around a knocking engine, and each one name a different cause for the trouble. Taking an engine apart is a costly piece of work and often much labor and expense could be saved if the cause could be accurately located before the parts are disturbed; in fact, the knock is not always in the engine itself, although it may sound so, but may be found in some of its attachments or fittings, and could perhaps be easily remedied by the operator if he only had the means of locating it. Therefore the sounding bar plan is a good one.

After determining about where the knock is located then further testing is outlined in chart 254.

*Piston Slap.

The usual cause of knocks is mentioned in lines previous. Another knock (which is caused by loose fitting pistons) is explained in the illustration, fig. 7, chart 254, called "**piston slap.**"

This is a knock that is very difficult to locate. About the only method for locating it is with the sounding rod and removing pistons and examining them. It is apparent that this knock can occur even though the piston rings fit tight.

Piston slap is due to the piston striking first one side of the cylinder, then the other. The looser the piston is the greater the slap. If piston is a good fit, slap is negligible, which is the case in the ordinary engine. The slap may be due to **worn cylinders** or in the case of **aluminum alloy pistons it may appear only when the engine is cold,** at which time the pistons are contracted and are much looser than when they are hot.

There may be two or more distinctive piston slaps during the cycle. However, it is likely that the only one that can be heard is the one that occurs when the piston shifts from one side of the cylinder to the other at upper dead center just as the explosion is taking place, as shown in fig. 7, chart 254. **When the piston is on the compression stroke, it is in contact with the right side of the cylinder.** As the crankpin swings by dead center, the inclination of the connecting-rod is changed from right to left, thus forcing the piston to the other side. **Under the full explosion pressure the piston** will strike a very heavy blow when it makes **the change.**

The piston remains in contact with this cylinder wall throughout the stroke, and when lower dead center is reached, the pressure on it is entirely relieved, so that it is quite likely that the piston is then able to more or less float between both walls.

On the exhaust stroke the piston is thrown gently to the right side of the cylinder, due to the downward pressure of the inertia, as well as the slight exhaust pressure. It is very doubtful that this ever causes an audible slap.

The piston remains in contact with this wall throughout the suction stroke; then the downward pulling force of the connecting-rod is resisted by the suction on the piston as well as the inertia.

At very high speeds inertia may change some of the details of this explanation, but these can hardly be of interest.

Other Causes of Knocks.

The troubles which are commonly the cause of a knock that developes on a hill and which is not perceptible on level ground are as follows: Lean mixture, magneto set too early, valves seat poorly, carbon in cylinders, poor valve adjustment, loose wristpin bushing, loose magneto shaft coupling and sticking valves. The cures for these may be taken up in order. They are as follows:

Lean mixture can be cured by opening the needle valve slightly or by closing the air valve. The former is preferable as it is easier to make a correct fuel adjustment than by an exact air adjustment. This adjustment should be made on the road. Take the car out on a hill and run it up in the condition that it is at present. Return to the bottom of the hill and make a change in the mixture by turning the fuel adjustment. When this is done run the car up the hill again and note if there is any decrease in the knock. If there is none or the change is only slight it is time to pass to the next cause.

Climbing a hill with spark too far advanced will always cause a knock. (see pages 67, 68 and 491.)

The cylinder nuts if loose will cause a knock and vibration (see page 584). End play in the magneto or pump shaft and often the coupling may be loose. Lack of proper lubrication causes most of the worn-out knocks which are heard, while many come from natural wear. The timing gears, for example, run in a bath of oil and yet, in time, the teeth become worn and with the excessive backlash or play, a rattling and sometimes knocking is heard.

Knocks are frequently caused by connecting rods being slightly bent out of true (in fitting cylinders down over the pistons) —this will also cause a "piston slap."

*See also, page 638, 609.

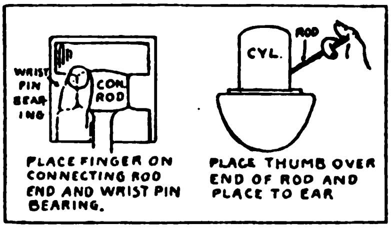

Fig. 1—To test for a knock; place finger on edge of bearing and connecting rod—have some one slightly rock engine, with switch off—the looseness, if any, will be felt. This plan can be used on Ford main bearings, but not on upper end of connecting rod, as it cannot be reached, but on some of the other engines it can.

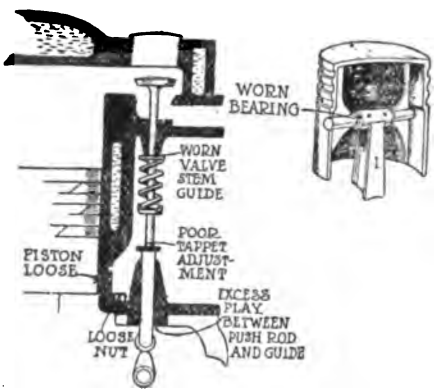
Fig. 2.—A sounding rod (rod of iron or steel) is useful to locate source of knocks.

Detecting noise of engine by sound, with a Sonoscope. Same principle as sounding rod above. Made by American Elect. Co., Chicago.



Places to Look for Knock.

Although not all are shown, above, most of the common engine noises and knocks are caused by either poor tappet adjustment, a worn valve stem guide, play in push rod guide, a loose piston or worn cylinder or loose cylinder nuts. Any of these will cause the engine to knock and they should be remedied immediately to prevent further complications.

*Testing For Knocks.

First examine the valves: Noises from worn valve stems, push rods or guides, are usually caused by too much space between the end of the valves and push rods, and is usually the cause of most clicking noises. They can easily be detected by "testing for noisy valves" as explained on page 634.

Wrist pin knocks can be tested as follows: On some engines it is possible to reach the piston or wrist pin and place your finger on it and bushing bearings and have some one rock engine slowly with the crank; then "feel" for the looseness—if wrist pin cannot be reached, here is another plan; while engine is running, short circuit spark plugs, one cylinder at the time, to cause it to miss, while engine is running slow or idle. When doing this, if piston pin is loose there will be a noticeable knock. **The surest method** is to remove the piston and connecting rod, and test on the bench.

To test for loose pistons; remove spark plugs and put ¼ pint of heavy oil in each cylinder, crank by hand slowly until oil works to the piston rings—replace spark plugs and start engine—see if the same noise occurs—if not, the heavy oil has cushioned the piston from cylinder and stopped the knock temporarily. Oil will soon get hot and run from the rings and piston and knock will occur again.

The piston, if loose, has a tendency to strike the cylinder wall, as shown in fig. 7 and explained on page 637. The rings may be tight, yet if piston is loose, this knock will likely occur.

The cam shaft and timing gears can easily be detected with the sounding rod. The timing gears will have a sound or growl that is entirely different from a knock.

When testing with the sounding bar, place thumb over end of bar and then place ear close to thumb. The closer you get to the noise the louder it will be.

To test for loose fly wheel; allow engine to run idle about 500 r. p. m., then throw off the switch and wait till it slows down to about 75 or 100 r. p. m., after which throw the switch on with spark slightly advanced. Repeat this a few times, and if fly wheel is loose there will be one distinct knock each time the switch is thrown on. Another method in testing for a fly wheel knock is by rocking it, (remember the fly wheel may be o. k., but some other part attached to it, such as the transmission or the clutch collar, may be loose).

A connecting rod lower bearing knock can be definitely determined by removing the hand plate at bottom of crank case, place your finger on one edge of the bearing and crank shaft. Have some one rock the fly wheel or starting crank gradually one way and the other (switch off). If loose you will feel it.

Main bearings can be tested in the same manner. A main bearing knock can also be determined when running car, by suddenly throwing into high speed or when pulling a stiff grade. If main bearings are loose, a distinct knock can be heard.

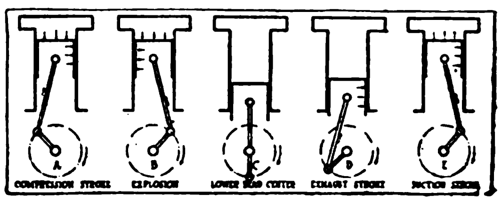


Fig. 7—Piston slap—see text page 637.

A very common trouble with aluminum pistons, which when cold contract and leave space between cylinder wall and piston. After engine is warmed up the pistons expand and noise ceases. Aluminum expands twice as much as cast iron. The Franklin car overcomes this by cutting three slots in skirt of piston with a spring ring placed in bottom which holds the lower part of piston to walls—as the expansion increases the ring tension gives accordingly.

CHART NO. 254—Locating and Testing for Knocks. Using a Sonoscope. Piston Slap.

A **spark knock** is due to advancing spark lever too far, causing combustion to take place before piston reaches top.
A **gas knock** is due to excess of gas, as suddenly opening throttle wide open. This knock also results from too rapid combustion, but the gasoline we have today does not burn so rapidly as to cause a knock—see page 161.
A **compression knock**, due to any cause which decreases the space between head of piston and combustion chamber—see page 640.

A circular describing a new principle of testing engine knocks by means of an air compressor can be secured by writing A. L. Dyke, Granite Bldg., St. Louis, Mo.

Pre-Ignition; Cause of Knocks.

It often happens that the mixture is ignited before the spark passes. This is termed "pre-ignition."

A rich mixture, or the burning of the lubricating oil, will leave a deposit of carbon on the piston head and combustion chamber. The intense heat of the explosions will heat this, and often it will remain glowing until the suction and compression strokes, exploding the mixture before the proper time—this causes a knock.

If the points of the spark plug are too thin and fine, they will get hot enough to glow in the same manner, and in such a case spark plugs with heavier points should be used.

Small points of metal, due to rough castings or other causes, should be filed down, using a fine file.

If the water circulation stops, or if the air cooling is not effective, the cylinder walls will get hot enough to ignite the charge, in which case the engine will continue to run after the ignition has been cut off. The remedy for this, of course, is to make sure that the engine is properly cooled.

Additional Tests for Knocks.

To locate the cause, first drive the car until the engine becomes warm or reaches its average temperature; second, select a run of about one-half mile, running into a grade of about 8 to 12 per cent, of whatever length may be had.

Drive the car from 10 to 15 miles per hour on the level road and maintain this speed up the grade, if possible. At this speed the engine should run quietly.

But, if, on the other hand, a slight but distinct metallic rap is heard, whether it be one, two, three, or four times to a revolution of the crank, **push rod or rods** will be found to have too much play.

Should it be a slight knock, which slightly increases as the car mounts the hill, mark this first; **worn piston rings,** which momently stand still in the cylinders while the piston travels its first 1-64 of an inch, or whatever the wear may permit, at the beginning of the power stroke. Second, it may be **worn pistons** which are being driven against the cylinder walls at the beginning of the power stroke.

This knock may instead have a distinct metallic sound which occurs once to every explosion and greatly increases as the throttle is opened or more gas is admitted into the cylinders. If this be the case mark it **carbon deposit** in the combustion chambers and on the piston heads, which becomes very hot and ignites the gas, causing **pre-ignition.**

Should the knock be either heavy or light but of a muffled sound, occurring either 1, 2, 3 or 4 times to two revolutions; this can be marked **connecting rod or rods;** which may be loose on the crank shaft, or the piston pins, or bushings may be worn. The one or more causing the knock may be located by holding down on the coil vibrator, or in any other manner that will discontinue the spark at the plugs separately. For example, if by preventing cylinder No. 1 from firing the knock ceases or is one less in two revolutions, then the trouble lies in connecting rod No. 1.

Should the engine pound, having the sound of a block of wood striking the ground, which will occur once to every explosion, but may be heavier at the explosion of any one cylinder, mark this **crank shaft main bearing.** In very bad cases this pound can be felt by the driver.

Again a flywheel that is loose on the shaft will cause the same kind of a pound (this, however, is very seldom). But if the driver will listen very closely he will discover that a crank shaft bearing has a double pound which occurs very close together, so close that when first heard it will sound like one pound.

A spark knock can be more readily felt than heard, because the power of the engine is being held back by its own ignition.

*A Seized Piston.

Occasionally the repairman receives a call to start an engine that has the symptoms of a seized piston, and has resisted the best efforts of owner of the car to start it. At such times the repairman must exercise the utmost ingenuity, for the owner has generally tried all the easy methods before he arrived.

In such cases, the first thing to do is to make sure that it is the engine and not some other part of the transmission or the rear axle that is at fault. The rear wheels should be jacked up, the emergency brake released and the gear shift lever placed in neutral. The wheels should turn freely and there should be no binding in the rear axle system.

The spark plugs should be removed, or the compression cocks opened, to relieve the compression. Then if the crank cannot be turned over by hand or by means of the starter, or by the two working together, the car may be towed with the gears in high and the clutch disengaged. As soon as the car has attained some momentum, the clutch may be allowed to engage gently, care to be taken not to allow a sudden motion which might strip the gears in the rear axle or even break a shaft.

If this does not free the engine, kerosene can be poured into the cylinders and allowed to remain for a couple of hours. This will have a tendency to dissolve any old oil which may have gummed the pistons to the cylinder walls. Then the car may be towed again and an attempt made to turn over the engine by engaging high gear. The engine can be turned over more easily in high than in low gear because it does not have to revolve so rapidly.

After one has succeeded in turning over the engine, one should open the drain cock in the bottom of the crankcase and drain out the mixture of kerosene and old oil. Then the new oil should be added, the radiator should be filled with hot water in order to expand the cylinders, and the spark plugs replaced. After starting, the engine should be run slowly under its own power for some little time, in order that the new oil may work to all parts.

***Meaning that piston is stuck to cylinder wall**—caused by excessive heat which can be due to: lack of water or lubricating oil or running a new engine at too high a speed—see pages 208, 189 and 489.

***Eliminating Compression Knock by Adding a Thick Gasket.**

A knock caused by too high compression sounds like a carbon or advanced spark knock. The compression may be reduced by placing a thick gasket between cylinders and crank case.

With some makes of engines this repair is a common one, particularly when the car is equipped with a heavy closed body.† In such cases a better job may be done by making the thick gasket of cast iron. It is made in a similar manner, but must be planed or milled to a uniform thickness and smooth finish. Otherwise the cylinders will be thrown out of alignment or the joints will not be tight.

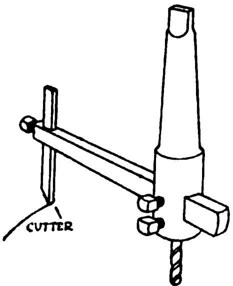

Fig. 3—Gasket cutting tool.

(1)—Remove the cylinders. (2)—Place the cylinders on a bench, and clean both the cylinder flange and engine base thoroughly. (3)—From a sheet of tin, make a template, fig. 2, which is an exact reproduction of the base of the cylinders, except that all the openings, such as piston and bolt holes are about ⅛ in. larger than those in the cylinders. The template is used as a pattern for marking out and forming the cylinder raising gasket, and permits the gasket to be made without going to the cylinder each time to see if it is being done right. A copper asbestos gasket does not have sufficient clearance to be used as a pattern. (4)—Procure a sheet of red composition board ¼" thick.

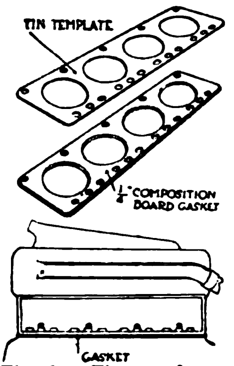

Fig. 2 — Tin template, and finished gasket. Lower cut shows gasket in position.

By doing this the cylinders have been giving a larger compression space and les pression. The result is that the comp knock disappears and the engine will pu better.

Note—It will be necessary to readjus rods after cylinders have been bolted securely. (Motor World.)

Engine Bearings.

With the exception of lubrication, the most important factor in the operation of an automobile is the condition of the bearings.

The three principal kinds of automobile bearings are: Plain bearings, ball bearings and roller bearings. The most important and those requiring the particular attention of the motorist, are the engine's three or five main bearings; the four or more connecting rod bearings; and the wrist pin bearings—all of which are usually plain bearings, lined with either bronze or babbitt metal bushings.

The plain bearing: Formerly, hard steel and phosphor-bronze bushings were regarded as the best combination, but in modern practice where large bearing surfaces can be used, white metal or babbitt is usually employed in preference.

In the case of small bearings which must sustain a heavy shock—such as, for example, the big ends of the connecting rods—white metal is scarcely hard enough to resist the spreading action of the impact. Phosphor-bronze or a composition metal, is therefore necessary here, but where sufficient surface can be obtained to ensure against this tendency, white metal—owing to its anti-frictional properties—is generally considered preferable. Being composed largely of lead the result of a failure in lubrication from any cause is merely to melt it out without harming the shaft, which would probably occur if a tough metal like phosphor-bronze were used.

The secret, therefore, of a successful white metal bearing, or indeed a bearing o kind, is a tru highly-polishe face on the jo The white bearing can th fitted compara tight, and wil idly accomm its surface to of the steel, long life will sured if the cation is corre

The Ryerson reinforced bearing consisting of a bronze skeleton used in combination with babbitt or other bearing metals. A new type of bearing bushing.

Grooving p bearing bushin allow for free lation of oil plained on pages 203 and 644.

Ball bearings: These are very good o main shaft, but to ensure success they shou large, (see page 109, note 1" balls used on engine), for it must be remembered tha surface contact of a ball with its race is p cally a mathematical point. For this reaso are not found to be successful as big-end ings, for the impact is too great for such s surface.

Roller bearings: These have, of course, a much greater contact area than ball bearings page 36), and have, therefore, been found quite successful in big-ends, but they must be carefully fitted, so that perfect alignment i sured. They will under these conditions sta for an incredible time.

It might be profitable to observe here that w there is a whip, even of small degree, ordi ball-bearings should never be used unless they of very great size. In a short, stiff shaft w center bearing, ordinary sizes and types are isfactory, but otherwise double row bearing the self aligning order should be chosen, there are at least two reputable makers stock this variety.

†To keep engine from pounding, at low speeds with open throttle. An open throttle fills the cyl with gas which of course increases the compression pressure—see also, foot note, page 909, lower compression is best for average work.

†Adjustment of Bearings.

The bearings which are most dealt with ings to be drawn closer together over the

(3)

The main bearings are burned-in first, fig. 6. All removable head type engines are burned-in in an up-side-down position, as shown.

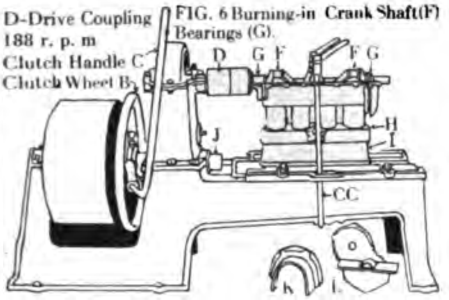

Fig. 6: Fairbanks Burning-in Machine. Burning-in the main crankshaft bearings on a Ford engine. A belt drives fly-wheel. The power is then transmitted through a clutch to gearing, thence to coupling (D), which drives crankshaft (F) at 188 r. p. m.

The same operation is used for burning-in the lower connecting rod bearings. The base (I) permits pistons to slightly pass cylinder block when burning-in the connecting rod bearings.

The main bearing caps are fitted so as to allow five or six thousandths rock on the crankshaft. Either draw-file off to this amount or remove shims. Bearing caps are then drawn down tight on crank-shaft, one at a time, then tested out with the turning bar or lever, fig. M5, approxi-

mately three feet long, which has two pins in it and fits into the flange of crank-shaft.

Each bearing should be shimmed up to same amount of tightness, then put in burning-in machine, fig. 6; connected with coupling D, then clamped good and tight with clamp rods CC.

The machine is then started by means of the hand lever C, which operates clutch, and crankshaft is revolved at 188 r. p. m., by belt power, for about two minutes until bearings begin to burn and smoke.

The hand wheel B, fig. 6, is for the purpose of testing the bearings to see if the burning-in operation is completed. When this wheel can easily be turned by hand, bearings are finished.

If one bearing should not get as hot as others, the operation should be stopped and either shims removed or cap draw-filed to tighten on bearing, thus insuring its being burned-in the same as the others.

After burning-in main bearings, engine is removed from machine, surplus metal is scraped out of oil grooves of bearings, and caps are replaced and lubricated.

Burning-in Connecting Rod Lower Bearings.

After main bearings have been burned-in and lubricated, pistons and connecting rods are assembled to engine, after being tested on alignment device figs. 1 and 2. The engine is then returned to the machine; mounted on the same base (I), fig. 6, which permits pistons to slightly pass cylinder head block. The operation is then the same as the burning-in operation on the main bearings just explained.

It is tested out by hand wheel B to see if completed and when the hand wheel B can be turned over freely by hand, then connecting rod cap is removed, oil groove scraped out and re-assembled.

Engine is now ready for running-in in oil, or burnishing.

Running-in in Oil or Burnishing, Main and Connecting Rod Bearings.

Engine is returned to machine in an upright position and instead of base I being used, the upper half of crankcase is bolted to oil sump on machine at M. The oil sump is filled with oil to oil level, fig. 7.

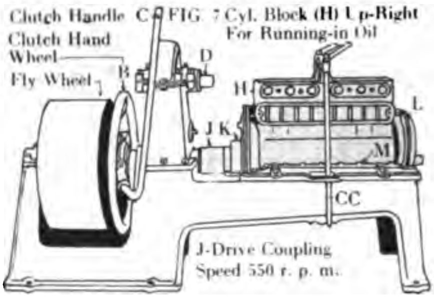

Fig. 7: Fairbanks Burning-in Machine being used for running-in the engine bearings in oil.

The main and connecting rod bearings, also piston, pistor rings are also run-in.

Note the lower coupling (J), which turns crankshaft at 550 r. p. m. is used in this instance

Engine is run at 550 r. p. m. until it is limbered up to the extent of being able to turn over the crankshaft by the hand wheel.

After this operation is completed, the engine is ready for complete assembly.

Up to this point on a large type engine, approximately three hours has been required to do these different operations.

...tight against the shaft, it ing at all.

*The bearing bushing is never scraped or removed, unless it is burnt or damaged. **See pages 203 and 644, showing oil grooves in these bearings. †See also pages 837 and 838.

‡Shims are used on all connecting rods, lower end, except those engines using oil pressure and hollow crankshaft. In this instance shims are not used as bearings would leak oil. Scraping is necessary to insure accurate fit. ‡Laminated Shim Co., 538 Canal St., New York.

*Eliminating Compression Knock by Adding a Thick Gasket.

(4)

Testing, Adjusting and Inspecting Engine On Machine.

The next operation is to test engine under its own power on the machine, per fig. 8.

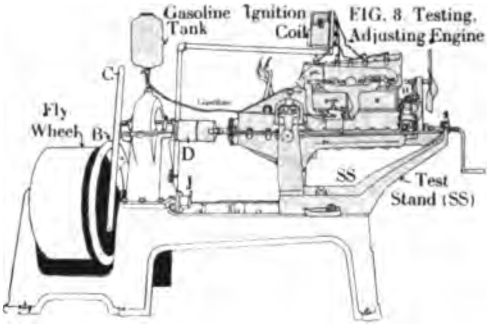

Fig. 8: Fairbanks Machine being used for Testing, Adjusting and Inspecting Engine under its own power, before installing in car. Note the stand (SS) has been attached to machine for this purpose.

After engine has been completely assembled, it is then connected to machine with the fixture (SS), as per fig. 8. Then connected with gasoline tank, which is furnished with stand. The ignition system is then connected with battery and hose connections may be made for running water through cylinder blocks for cooling. The exhaust should be piped out-of-doors to eliminate fumes.

After engine is ready for this operation on machine, the clutch (C) is thrown in and engine is run until it starts under its own power, then machine is shut off and transmission of engine is set at neutral point and engine run until freed up to the point of being able to easily crank by hand.

After all adjustments for oil leaks, ignition, valves, etc., are made, engine is **ready** to be placed in the car, rather than to have to tear it out again for some trivial reason which could not be detected until engine had been replaced.

Boring Cylinders.

The Fairbanks Co. recommend the "boring" process for enlarging cylinders. They claim that boring is superior to "grinding" for several reasons; one reason is due to the fact that the cylinder walls are more porous after a boring process, thus it retains oil in the pores which produces a more lasting lubricating effect.

Where To Obtain Up-To-Date Equipment For Modern Repair Shops.

There are several firms who manufacture different devices for service station equipment, but there is one concern who have branches over the country and are in position to supply a complete line of garage and repair shop equipment of anything necessary in service station work, for any make of automobile, truck, small marine or airplane engines. This is the **Fairbanks Co., Service Station Equipment Division, 3701 South Ashland Ave., Chicago, Illinois,** with branches in all principal cities.

A very interesting and instructive catolog may be obtained by writing this concern and mentioning Dyke's Automobile Encyclopedia, or Home Study Course.

This catolog shows engine stands, brake relining machines, piston vise and press, cylinder reboring machines, rear and front axle overhaul stands, tanks for washing engines, radiator test stands, radiator test plug sets, crane hoists, soda washing tanks, portable cranes, hoists, overhead track systems, re-babbitting outfits for bearings, all electrical testing apparatus, air compressors, tools, motors, gasoline engines, stock bins, etc.

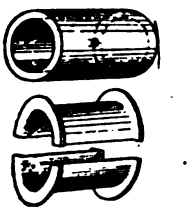
---

*See also pages 627 and 535.

†To keep engine from pounding, at low speeds with open throttle. An open throttle fills the cylinder with gas which of course increases the compression pressure—see also, foot note, page 909, why lower compression is best for average work.

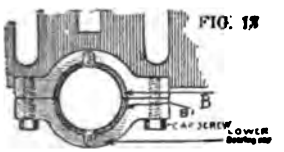
†Adjustment of Bearings.

The bearings which are most dealt with on an engine are the crankshaft main bearings, and the upper and lower, connecting rod bearings.

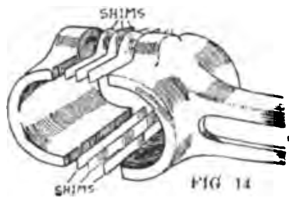


The main bearings on a crank-shaft are provided with bushings, upper and lower, which are made of white metal or composition alloy and are split as shown in lower illustration.

The bushings (B & B 1, fig. 13) are placed in the bearings which have between them thin metal shims, (two types of which are shown in figs. 14 and 15.) When worn, a shim is removed (one from each side) which allows the two bushings to be drawn closer together over the shaft.



The same principle applies to the lower connecting rod bearings, but on the upper connecting rod bearing, the bushing is in one piece, and not split (as will be noted in figure 10, page 645.) The subject of bushings will be treated more in detail further on.



Worn Bearings.

Whenever a bushing has become worn until the inner surface is no longer absolutely round, it makes itself known by a peculiar knock. On examination it will be found that the fit is loose and that the shaft has an excessive amount of "play" or lost motion and in the case of a main bearing, the shaft is out of alignment—see page 643 for crank-shaft alignment.

†Adjustment of Main Bearings.

Ordinarily the main bearing on crank shaft, if slightly loose, only requires to be taken up as most bearings are fitted with **shims.**

Taking up main bearings: first, take down the oil pan. To do this remove all the bolts underneath and all bolts at each end of pan. Then remove lower oil pan. The bearings on most engines are fitted with brass or other forms of separators of a standard thickness made up of thin shims in various gauges, .001 in. to .005 in. thick.

‡Shims: On modern bearings there are usually three shims of different thickness, under each side of the bearing cap. The thinnest shim being at the bottom.

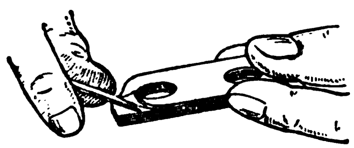


Fig. 15. The laminum shim.—note the laminated layers. In the illustration, the top layer is being started with a knife blade, enough to get a hold, then it can be peeled off.

‡The latest type of shim is the laminated shim shown in fig. 15. It is made of thin layers (.001 inch to .005 inch in thickness) of laminum which can be peeled off as desired. This type of shim can be used in the crank shaft main bearings and also in the connecting rod lower bearings, per page 837.

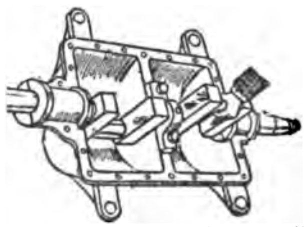
***To make proper adjustment** simply remove one or more thin shims from each side of the bearings. Be careful not to make the bearings too tight, see page 838.

The bearing cap, usually referred to as the lower bearing, must be drawn up tight. Not against the shaft but against the shim or spacing sleeve as shown at (A) fig. 3 page 643. If drawn tight against the shaft, it will burn out, and if left loose it will pound and perhaps strip nuts off the cap screws. A really mechanical job cannot be made without shims or their equivalent.

The rear main. bearing is the bearing which usually requires attention first on account of weight of fly wheel and torque.

To test after taking up; turn the starting crank with pet cocks open. If you can spin the crank shaft it is not quite tight enough. It should be adjusted so moderate pressure on crank will allow shaft to turn.

Many mechanics, when taking up bearings test by getting bearings just tight enough so fly wheel can be moved. In other words after a little practice they can tell just how tight bearing ought to be by being able to barely turn crank shaft by hand, by means of the fly wheel.



To test after scraping a bearing; the crank should turn by hand but with slight resistance. See also pages 837 and 838.

Remember there is a possibility of getting the bearings too tight, and under such conditions the babbitt is apt to cut out quickly unless precaution is taken to run the engine slowly at the start.

When bearings have been taken up don't forget to see that all nuts are securely tight and the cotter pins inserted.

If the bearing is not fitted with shims, which is unusual, then it will be necessary to dress the sides of the bearing so it will make a closer fit.

All of the weight and most of the wear is on the lower part of the bearing called the lower bearing cap. For this reason there is not much wear on the top. The 1910 Ford engine did not have a bushing in top of the crank-shaft bearing at all.

*The bearing bushing is never scraped or removed, unless it is burnt or damaged. **See pages 203 and 644, showing oil grooves in these bearings. †See also pages 837 and 838.

‡Shims are used on all connecting rods, lower end, except those engines using oil pressure and hollow crankshaft. In this instance shims are not used as bearings would leak oil. Scraping is necessary to insure accurate fit. ‡Laminated Shim Co., 533 Canal St., New York.

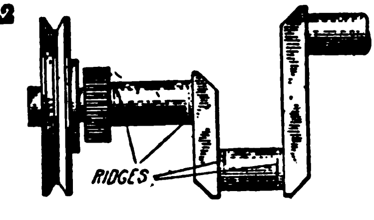


Fig. 6.—Scored crank shaft. Note the ridges. This is only a slight score. This can be polished off by encircling the shaft with fine emery cloth saturated in oil and making a steady, even motion up and down. The crank must be thoroughly washed afterwards to remove emery dust.

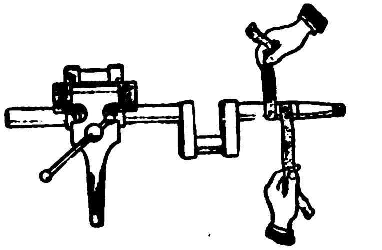

Fig. 1.—Cleaning up roughened surfaces of crank shaft with very fine emery cloth.

Fig. 2.—A grinding tool or "lap" for trueing up a worn shaft when proper grinding machine is not available.

Crank Shaft Repairs.

When fitting bearings the crank-shaft should first be examined by seeing or feeling if there are ridges or uneven surfaces on it. If so, it will cut the bearing and cause trouble, and fitting of bearings will be a waste of time.

If crank-shaft is scored, by ridges or rings being on it, then place it between grooved wood blocks and carefully emery it down (fig. 1). Fine emery cloth in strips 1½ inches wide and well oiled should be used as shown. Emery tape is better if obtainable. Note the emery strip encircles the shaft, and a long steady movement is imparted to it in order that there is no tendency to make it oval.

If a **crank-pin is found out of true (not circular), by testing with calipers and micrometer, and is more than .0015 out of round, then the best plan is to have it ground true on a special grinding machine.

The cause of a crank-pin (where lower part of connecting rod fits) being out of true, is often due to a flat spot, due to explosion pressure constantly at one point. Result, connecting rod bearing will not fit true and will be bind, even though properly fitted. The only remedy is to have the crankshaft ground on a special crankshaft grinding machine. (H. & H. Machine Co., St. Louis, Mo., grind crankshafts).

Where crank-pin is only slightly out of true and a grinding machine is not available, then file up the untrue part with a very smooth file as accurate a circular shape as possible, testing frequently with the calipers. A lead "lap" is then made in clamps (fig. 2). This is bored out to a size, and paper or card shims inserted between the two halves so that the two halves can be gradually closed down by the bolts onto the crank-pin. This lap is dressed with fine emery and oil and worked around the crank-pin by hand till a good surface is obtained. **Crankpin is part of crankshaft to which connecting rod is attached.

*Scraping and "Spotting In" Bearings.

The bearings on a crank-shaft are the lower connecting-rod bearings and the bearings which carry the crank-shaft, called the main bearings. In modern engines these are usually babbitt, white metal, brass, or a similar metal which is soft, easily cut and tough. To scrape in a set of bearings usually requires 12 to 20 hours, depending upon bearngs being out of line.

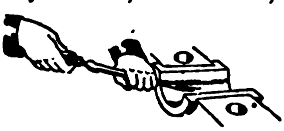

Fig. 4.—Using a scraping tool on a bearing surface.

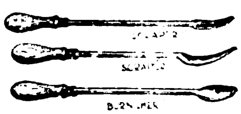

Fig. 3.—Bearing scraping tools which can be secured at any supply house or made of old files.

Connecting-rod bearings: After sufficient shims have been removed from between cap and rod so that bearing fits tight on shaft, the rod nuts are taken off and the **shaft** bearing surface given a very light coating of "marking" compound.

The marking compound is Prussian blue which can be secured at any supply house and comes ready mixed. A **little** dab on the fingers is sufficient to wipe on the shaft as a very light coat is required. If too much is given it will run all over the bearing and spots will show which should not be scraped.

Marking or "spotting-in" bearing: Put connecting rod in place, put on cap and draw up tight. Be sure caps are fitted on according to the punch marks on cap, and rod is on right side forward. Then rock back and forth and swing it around shaft twice.

Next remove nuts and bearing. The "high spots" inside of bearing will be found marked in blue, showing that at these points the crank touched, but the part which is white, the crank did not touch. Therefore, the problem is to get the high spots down until the bearing will mark all over, by **scraping,** which is a slow, tedious job, for if too **much** metal is removed it cannot be replaced.

This marking or "spotting in" process is repeated from time to time till the whole surface is marked as shown in D, fig. 8. In practice it is not possible to get every white mark off the bearing, and if say, not over one-tenth of the total surface, let it go, it will wear in.

Adjustment: When scraping is completed and all nuts down, the rod should be just stiff enough to turn by hand and if placed in a horizontal position it should not fall by its own weight, but should move when pushed by hand. If fitted too tight seizure will result.

After the scraping is done the burnisher shown in fig. 3 may be run over the entire surface of the bearing to shine it up and smooth the surface.

The scraping tools can be made of **half** round files as the quality of steel and temper is just right—or purchase at a supply house.

The rod bearings should now be tested for parallelism (see pages 659, 646, 649). **The** piston pin and the crank-throw must be parallel, and the bearings that they move in must also be parallel, or binding and rapid wear will take place.

If the small end bearing of the connecting rod is worn it will be necessary to make a new bush and ream it out to a true fit on the piston pin to about .002 inch clearance (see foot note, page 645).

Scraping main bearings, see page 643.

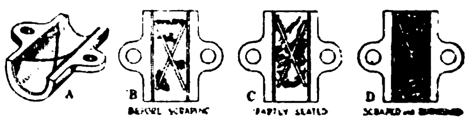

Fig. 8.—Showing appearance of markings as the scraping proceeds. See page 644 showing oil grooves.

—continued from page 641.

Draw filing (see fig. 2 and page 708) of a bearing cap is necessary, as on the Ford and other engines where shims are not used. (see also, foot note, page 641.) After dressing down on the sides, try the surface of the sides for high spots by holding a steel rule or scale across it at several points and angles (fig. 5). If there are high spots they should then be dressed off with the file. After dressing the sides, then test the inside of bearing by "spotting-in" and then scrape. On bearings using shims, it is usually, only necessary to remove shims to take up bearings.

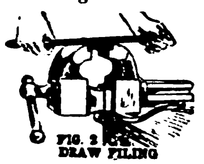

FIG. 2 DRAW FILING

FIG. 5

**If bearing bushing is cut or burnt, then it can be scraped or replaced with a new bearing and "burnt-in." Scraping is best as it insures an accurate fit.

In taking up slightly worn connecting rod bearings, first check the crankpin with micrometer to see that it is not out of round—see third paragraph top of page 642.

Adjustable Bearings.

Unlike most engines, the Reo main bearings are adjustable from the outside, and it is only necessary to remove the mud pan to reach them. A, are spacing sleeves and B, are locking studs. Take up bearings with socket wrench (SW) until shaft turns a little bit hard.

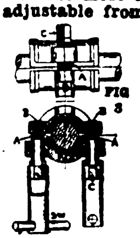

FIG 3

Connecting rod bearings are adjusted through the handholes in the side of the crankcase. Connecting rod lower ends are "hinged" on the Reo.

†Scraping Bearings and Crankshaft Alignment.

Scraping the connecting-rod bearings and how to test by "spotting-in" the bearing is explained on page 642. Scraping is resorted to when a bushing is burnt or damaged or when fitting new bearings, or after trueing crankshaft or crankpin.

The adjustment and fitting of main bearings is also explained on pages 837 and 838.

‡Before marking or scraping the main bearings, each bearing cap is to be set down tight with the nuts and tried for tightness, the other bearings being loose at the time.

To scrape the main bearings: The **upper** bearings are finished first, therefore crank case is laid up-side down, per fig. 2, page 646.

All the upper main bearings are worked at one time, so that the shaft will align.

***Crank shaft alignment:** Very likely the center bearing will be high and the shaft will rock on it. If so, it will have to be scraped down till there is no rocking and until all the bearings mark all over. Great vibration as well as wear, can be caused by neglecting this. If center bearing is too low, which would be shown by no marking at all, then end bearing will have to be scraped out till center bearing marks all over.

In marking or "spotting-in" these bearings the weight of crank shaft is sufficient. Do not put on the caps at all as they would force or spring the shaft down and mark the low part of bearings.

The cap or lower main bearings (after upper bearings are completed) are treated in a similar manner as the connecting rod caps, page 642. They are scraped down to a perfect marking. **A very important point is to "spot-in" and fit the rear cap first and** test it for stiffness then loosen it, then "spot-in" and test the next and loosen it and the other the same. After doing this then tighten down on all. Otherwise, if each bearing is tightened as you proceed, the bearing being fitted could not be properly tested for clearance.

After "spotting-in" main bearings, caps are tightened down and "run-in" by belt power, using plenty of oil. Caps are then removed, bearing surface examined, then replaced and proper clearance given by removing a shim, if necessary.

Adjustment; when lower caps are fitted and nuts drawn up tight, the shaft should turn with some resistance. Some repairmen judge the amount of resistance by being able to move the crank shaft with one hand (per page 641), or if bearings are being taken up under engine, by just being able to move or turn fly wheel. The bearings must **not be so tight they will overheat** and seize.

If the shaft turns too hard, do not think that loosening up the nuts is the remedy. In such a case an extra thickness of shim brass will have to be put in so that nut can set down tight and still allow shaft to turn.

Connecting rod lower bearing is often "burned-in," by fitting new bearing caps and then run on power for a few minutes, then cap is removed, surface examined to see if cut, if so it is scraped, then correct clearance given with shims (.003 to .004").

Connecting rod upper bushing is usually refitted with new bushings and reamed to .002 to .003" clearance.

Bearing Pointers.

After fitting bearings, run engine at moderate speed for first 500 miles, using plenty of good oil to work bearings in. See also page 798.

Before marking and after scraping, dust metal chips out with a small paint brush.

See that oil grooves are not clogged and are deep enough (see page 644).

Wash all parts off with gasoline or kerosene.

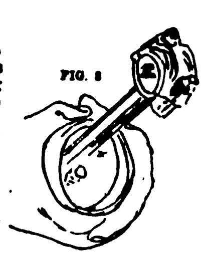
Have the scrapers sharp and never try to scrape with nicked scrapers.

In renewing bearing bushings, care must be taken that they are of about the same thickness of metal, as the original ones. If too thick the pistons will be pushed higher into cylinder and alter the compression and cause vibration. On two-cycle engines it would change the port timing.

***A Reamer,** per page 792, fig. 66 is used extensively for aligning crankshaft.

†Bearings are also sometimes ("burned-in" or "run-in"), **where a quick job is desired,** by fitting new bushings, one at the time, then bearing caps are drawn tight, then belt power applied until worked in. The caps are removed, bearings inspected and high spots scraped down, proper clearance given by removing shims, if necessary and caps then fitted. It is always best to scrape a bearing and spot it up first, however. ‡An equal number of shims on each side (at least 3/32" total) should be on each side when drawn down. **On the Ford, a new connecting rod can be replaced, if babbitt is burned out.

Fig. 8. After fitting a new piston pin the piston should be held as in fig. 8. The connecting rod should hardly be able to turn of its own weight, but should drop gradually as the piston is jarred.



Another point — all connecting rods should be of equal weight. They can be weighed separately and filed or ground down to weight if not too great a difference—see page 818.

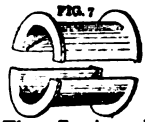


Fig. 7—A split bushing for lower end of connecting rod.

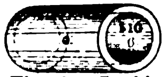

Fig. 6 — Bushing for upper end of connecting rod or piston pin.

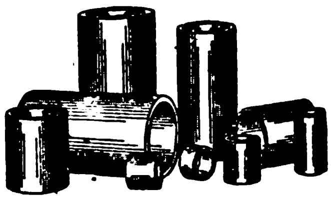

Fig. 8—Bronze bushings needed in every repair shop. Can be secured at brass foundry. Call for "bearing bronze."

Bearings.

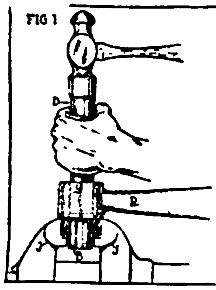
Strictly speaking, the bearings of a shaft are composed of two different metals. The real bearing is cast integral with the engine or machine of which it forms a part, and the other part (on which the shaft really bears) is known by various names, such as linings, bushings, brasses etc. They are made of various metal, such as babbitt, phosphor-bronze, white metal alloy etc.

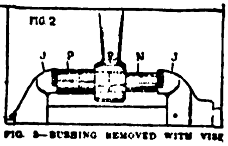
The adjustment and replacement of bearings in an engine, or some part of the transmission, such as a gearbox, is a matter requiring a good deal of skill and experience to effect.

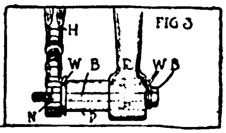
With the exception of the small end of the connecting rod (figs. 1, 2, 3) all bushings are split lengthwise (fig. 7). The small end of the connecting rod has a plain phosphor bronze bush (fig. 6) forced in fairly tight. When worn, a new bush is fitted which is turned and bored to a free fit without any trace of rocking or end movement.

The split bushings (fig. 7) in time wear oval, mainly on the lower half. In most cases a slip of metal called a "shim or liner" is inserted between the upper and lower halves of the bearing, which pieces can be filed down or one or more layers peeled off, (if laminated shims are used) for adjustment.

Many bearings are "lined" or bushed with "babbitt-metal," bronze or anti-friction alloy. When worn, the bearing halves are relined and bored out true. The surface is tinned and the molten metal run in either solid to fill up the bore completely or around a mandril smaller than the shaft. A true bore to fit the shaft is then made in the lathe and the bearing cut through, after which the necessary oil channels are cut in the surfaces. (see figs. A and B below.)







Piston or Wrist Pin Bearings.

Fig. 1—One common way to remove a bushing. Jaws J of vise are opened far enough so end of rod R rests upon them and at the same time give sufficient clearance for bushing to pass between as it is driven out. To drive out bushing B, a drift D (usually bar of steel) and a hammer are required.

Fig. 2—A better way; jaws J of the vise are opened wide, a piece of pipe P, large enough to clear the bushing, is placed against the inner surface of one jaw, the rod is carefully adjusted and pressed against it to hold it in place until the drift or solid pin N is adjusted into place, then draw vise together to squeeze the bushing out of the rod R into the pipe P. If no vise is at hand with a large enough opening, recourse can be had to method shown in fig. 3.

Fig. 3—Another plan; a bolt B, some washers W, a piece of pipe P. a nut N, and a wrench H may be employed as shown. By this method, a bushing may be removed without danger of springing or burring up connecting rod end.

To remove a tight piston pin, first extract the locking rings, then plunge the piston in boiling water. This will release the grip of the piston on the pin and permit it to slide out.

When a bearing is adjusted, it must also occupy the same relative position as before in its bed, and to effect this, packing the lower half with very thin sheet phosphor bronze or foil may be necessary. Various thicknesses from 1-1000 inch up can be obtained for this purpose. A good practice is to slightly "ease off" the bearing at the dividing line, to avoid any risk of binding.

It is of great importance to the running of a bearing that the shaft be dead true and cylindrical and the surface quite smooth.

When fitting a plain bush (fig. 6) very moderate pressure should suffice to drive it in place. A tight fit may cause the bush to bulge, necessitating reaming out to make it fit.

A bush that is an easy fit requires dowel pinning to prevent it turning round. Particular care should be given to cutting oil channels, and to note, in the case of plain bushes, that the oil holes are drilled all the way through.

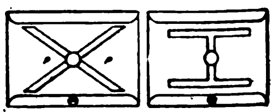
Hardened steel bushes can be used, providing the shaft is case-hardened to resist wear.

This type of bushing requires grinding after hardening, and the running clearance should be a shade more than for phosphor-bronze. Ample oilways should be cut in the surface as per B, below. (see also page 203).

Oil Grooves in Bearing Bushing.

Another important feature is the shape of the oil grooves themselves. The usual practice is to make the grooves as shown in the figure at A, like a letter X. The result of using this style of groove is that the areas of the bearing at p,p, run dry. A careful series of tests has shown that the type of oil-groove shown at B and made in the form of the letter H, gives results far superior to the other. Some very bad cases of poor lubrication and heating bearings have been cured entirely by the simple expedient of changing the type of oil groove from that shown at A to that shown at B. (E. W. Roberts in "The Gas Engine.")

Keep oilgrooves out of the pressure side of your bearing, whenever the pressure is one sided, as in the crank-pin bearing. —see also page 203.



A B

CHART NO. 256—Bearing Bushings. Wrist or Piston Pin Bushing Removal. Oil Channels.

*Piston or Wrist Pins.

The piston or wrist pin is the pin on which the upper part of the connecting rod swings. It is sometimes made of solid steel but usually of hollow case hardened steel tubing. It is also called "gudgeon" pin. It is non-adjustable, therefore when worn the pin or bushings must be renewed.

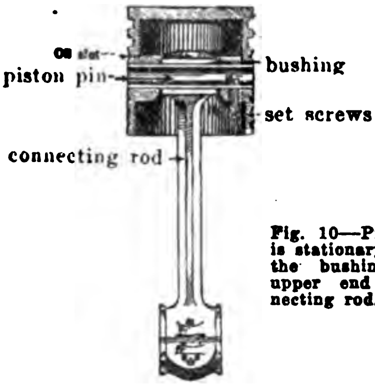


Fig. 10—Piston pin is stationary — note the bushing is in upper end of connecting rod.

The stationary piston-pin, fig. 10, has a **bronze bushing in the end of connecting rod** which oscillates on the piston pin. The pin is held tight by a set screw.

Oscillating piston-pin is where pin is clamped to upper end of connecting rod, as C, fig. 11. The **bronze bushing in this instance is pressed into bosses in piston and** piston pin oscillates in the bronze **bushings.**

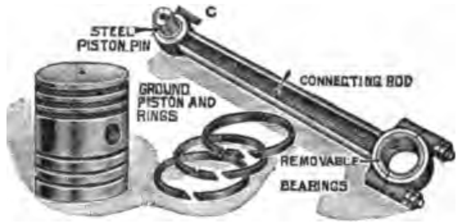

Fig. 11—Piston pin oscillates in bushings in piston bosses. Note connecting rod is clamped to pin at C.

To remove piston pin when stationary, see page 650, fig. 22. Another method for holding the pin in place is by means of a spring pressed plunger which is in the inside of the boss inside of piston. To remove piston pin a small wire forces plunger up and pin is driven out.

To remove bronze bushing in upper end of connecting rod or piston bosses is sometimes a difficult task (see figs. 1, 2 and 3, page 644 and fig. 22, page 650). Quite often a reamer is used to ream them out. The idea is to renew the bushings.

The piston pin may also be worn, therefore examine and replace it when renewing the bushings if worn. **As a rule, wrist pin and connecting rod bearings are apt to wear soner than the main bearings.** Therefore test for looseness per page 639 and below, before working in the bearings.

**Connecting Rod—Lower Bushing.

To test to see if a connecting rod is loose: remove lower crank case. Take hold of rod and see if there is end play, by a vigorous push up and down, if so, the looseness can be felt.

Don't mistake the side play however for the looseness, as a slight amount of **side play is necessary.**

The connecting rod, lower end is divided into two parts, usually with shims placed between, see fig. 14, page 641.

What has been said in the reading matter, concerning the main engine bearings also holds good for the connecting rod bearings. The two bearing halves may be brought closer together by the removal of some of the "shims" between them or dressed down with a file, if shims are not provided. It is policy to take off enough metal to allow for a few shims, so that when taking up is again required, it will only be necessary to take out 1 or 2 shims—see page 838.

In the majority of engines the removal of the lower half of the crank case is necessary before the connecting rods can be reached.

Note that there must be about $\frac{1}{32}$ inch side play between the sides of the connecting rod bearing and side of crank shaft arm—also at upper end. (see pages 659, 646, 649 for aligning connecting rods.)

Pistons.

Pistons are made of cast iron for all ordinary uses. In many instances where speed is desired, an aluminum alloy called "Lynite" is sometimes used.

The cast iron piston expands less than steel or aluminum alloy pistons. The latter expanding under heat more so than cast steel.

The piston proper, is made **with grooves for rings,** (R), which are placed as shown in illustration, which is the Ford piston. Note there are two rings above piston pin and one oil-ring below. Sometimes an oil groove, per fig. 6, page 74, takes the place of the oil-ring. B is the bushing for piston pin. See also, page 655.

The average automobile engine piston is fitted with three rings above piston pin and one below. **Pistons are usually ground to fit cylinder** but not a tight fit.

Piston replacement: Three conditions make it necessary to replace a piston: (1) scored; (2) undersize; (3) leaky. If it is not scored too badly it can be dressed down with a fine file. If leaky, see foot note, pages 656 and 791. New rings will help some on undersize pistons, but slapping will occur. See also, pages 609, 654, 655. See page 791 relative to piston clearance on the Ford engine.

Where speed is desired, the lower part of piston is frequently drilled with holes and piston is made of aluminum alloy to lighten them as much as possibe (see index "Tuning engine for speed").

‡Aluminum Pistons.

It is claimed by manufacturers of same to be superior to cast iron for the following reasons: They are about one-third lighter. The inertia of the reciprocating piston is reduced approximately

—continued on page 651.

*The piston pin bushing is usually a bronze bushing pressed into place and in case of renewal will have to be driven out per pages 644, 650. If piston pin becomes loose it will score cylinder, per page 653. †Oldsmobile Co. recommend .002" clearance in upper end of connecting rod which is necessary to take care of different expansions between bronze and steel when heated. **See also pages 837 and 838. ‡Foot note, page 651.

***Fig. 1.—Testing connecting-rod.** A jig or fixture for testing the alignment of connecting-rod assemblies is shown. The crank bearing of the connecting-rod is attached to an arbor that is part of the base, and the piston swung across the face of the disk that is fastened to an upright. This disk is made similar to a face plate and is necessarily at right angles to the crank bearing arbor. Any misalignment is instantly detected and corrected by bending the connecting-rod so that the side of the piston forms a line contact with the surface of the disk. This prevents the possibility of unequal wear of cylinders due to off-center pistons—(Motor World).

Fig. 2.—Crankshaft testing. The crankcase may be used as a fixture for testing the alignment of the main bearings of the crankshaft with little difficulty. The case is placed on the bench in the position shown, a strip of pasteboard about 1 in. wide and 1/64 in. thick placed beneath the front and rear bearings of the crankshaft. By these the shaft is raised from the center bearing and side play prevented. A pointer is then clamped onto the side of the case at the center bearing, and by turning the shaft the amount it is out of true is determined. This method is not only better but quicker than testing in a lathe.

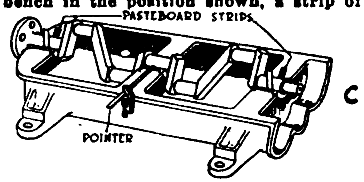

Fig. 4.—Removing pistons is necessary when working on the wrist pin.

The method of removing piston (Overland for example) is to take off the bottom half of the crank case and then remove the connecting rod bearing cap from the rod attached to the cylinder which it is desired to remove. The bearing cap is held by two bolts fastened by castellated nuts. When these are removed the rod can be swung to one side out of the way of the crank shaft and the entire assembly withdrawn from the cylinder in the manner illustrated, fig. 4. The piston pin can then be driven out with a punch after which the bushing can be readily removed.

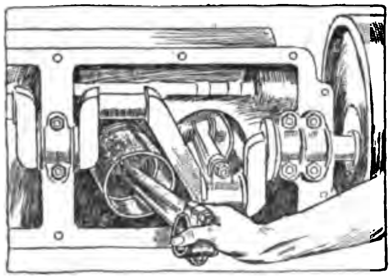

Fig. 4—Method of withdrawing piston and connecting-rod assembly after the bottom half of the crankcase has been removed

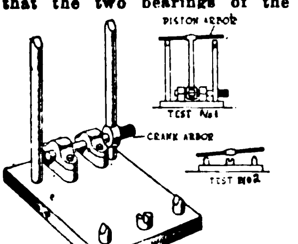
This plan however cannot be used on engines where the pistons are too large, or a 5 bearing crank shaft or on a 6 cylinder engine. The procedure is then to remove the cylinders and lower part of crank case and loosen the connecting rod caps and take pistons from top of cylinders, or it may be necessary to raise cylinders from off pistons.

***Fig. 11. — Connecting rod alignment:** It is essential that the two bearings of the connecting-rod be in perfect alignment. Not only should they be parallel, but they should also be in the same plane. The jig illustrated is designed to test these with one setting. The connecting-rod is held on an arbor, and a second arbor placed in the wrist pin bearing. Knife edges are used to check the alignment of the two arbors, one pair for parallelism horizontally, and one for vertical parallelism, the rod being swung from one test position to the other. (Motor World.)



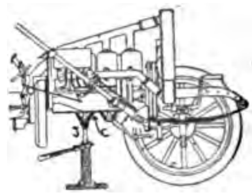


Fig. 3.—One method for testing for a loose bearing is shown in the sketch. Run the car over a pit, if possible, although the bare floor will do.

Raise the car by means of a jack to suit the conditions for testing. If the rod bearings are to be tried, run a jack head against the lower half of the connecting rod bearing and work the jack handle up and down. The smallest amount of play can be detected in this way, especially on the main bearings, where the presure of the jack is applied on the crank shaft against the weight of the car and "play."

Figs. 5 and 6.—One method of straightening a slightly bent crank shaft is shown. This shaft is bent as indicated by the dotted line, A, fig. 5, only to a very much less extent, the bend not being visible to the naked eye except when the shaft is revolving in a lathe with a tool or other object held stationary, close to the center bearing surface.

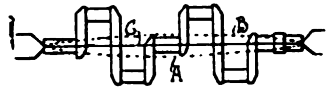

Fig. 5—Bent crank-shaft.

In testing for a bent crankshaft, one should not be misled by a bearing surface of the shaft that is probably worn out of round; the test should be made at the side of the bearing where little or no wear is liable to take place.

There are few repair men who will undertake to straighten a bent crank shaft, and by many it is claimed to be impossible to make a lasting repair to a shaft which is out of true. However, as the repairman is occasionally called upon to fix-it-up, one means employed is shown.

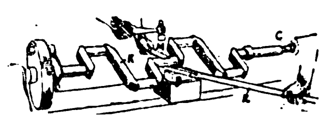

Fig. 6. Method of straightening.

The shaft K is fixed between the centers C of lathe, blocks B, are placed upon the lathe-bed for a fulcrum, and a bar of iron R, or preferably of wood, is used as a lever. If an iron bar is employed a piece of brass, wood or lead should be placed between it and bearing surface of shaft for protection.

Assuming that the shaft is bent as indicated by the dotted line A, fig. 5, it is pried up with the bar till it assumes the position indicated by the dotted line B, and while held in this position an assistant holding a piece of brass, M, on the bearing surface with one hand, and with a hammer in the other, strikes the shaft a sharp light blow.

The bar and blocks are then removed, the lathe started, and the shaft tested again for results. This treatment is repeated again and again until the shaft is straight as indicated by the line O. It is generally a long and tedious job, depending greatly upon chance and the ability of the operator of the bar to guess the proper amount of pressure to apply and the proper place to apply it.

CHART NO. 257—Testing Connecting Rod and Crank Shaft Alignment. Straightening a Bent Crank Shaft. Testing for a Loose Bearing. Removing Pistons.

*See also, page 659 and foot note page 649.

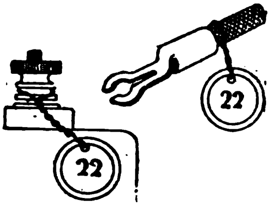

Fig. 1—All terminals should be marked in some simple manner, to facilitate the assembly. Price tags are used in the above method

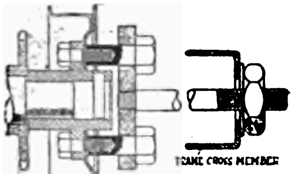

Fig. 2—Special puller for removing the fan pulley flange from the crankshaft. It may only be used when the engine is in the car, and is attached to the flange bolts

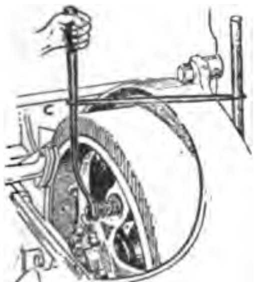

Fig. 3—All operations on the clutch springs are made easy by the aid of the compressor shown. It consists of a forked lever, held by a steel wire to a rod braced on the engine support. The forked lever is also an effective tool for removing valves

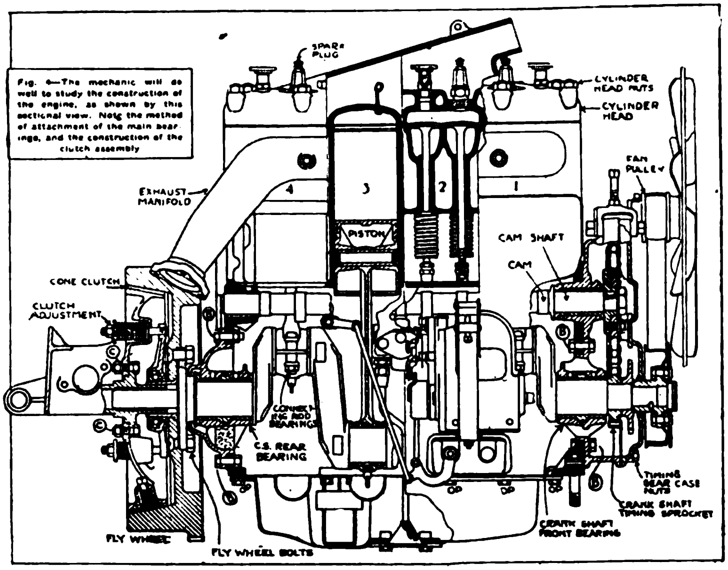

Fig. 4—The mechanic will do well to study the construction of the engine, as shown by this sectional view. Note the method of attachment of the main bearings, and the construction of the clutch assembly

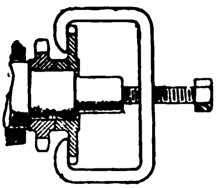

Fig. 5—All injury to the timing sprockets is prevented by the use of this puller. It can only be used after the timing cover and chains are off

The following outline of work will give the reader an idea as to how to use system in connection with repair work. While the example treats on main and connecting rod bearings, still the main features and manner of doing the work will apply to other work of a similar nature. There is a right time and a wrong time to remove each part. The following order has been found the most efficient by the Overland Service Station in New York and was published in "Motor World," a leading automobile publication.

Indications of Wear.

Heavy, dull pound—main bearing.

Lighter knock, usually worse when engine is idling—connecting rod bearing.
(Inspection of the bearings is always essential before taking the engine down, as the trouble may be somewhere else.)

How to Determine Where?

1-Remove pan.

2-Remove hood.

3-Draw oil from base.

4-Remove base.

5-Place jack beneath flywheel, and work it up and down. Any play may then be felt in the main bearings, see fig. 3, page 646.

6-Work connecting rod bearings up and down, to determine looseness.
Note—A chain or tackle block, secured to the ceiling, is necessary to remove the engine from the frame; and some sort of a stand to rest it on when removed. These, the standard shop tools, and the few special tools described later, are all that is essential to efficient work. If the connecting rods only are loose, they may be tightened without removing the engine from the frame. Looseness in the main bearing necessitates a complete removal and tearing down of the engine.

1-Find the trouble.

2-Study the location of the defective part, and its relation to other parts.

3-Determine the commonsense method of getting at the defective part—and do not remove any part unnecessarily.

4-Lay out, either in your mind or on paper, the successive steps necessary to do the work. Efficiency demands that you do all possible work on one part from one position.

5-If necessary, mark each part on removal.

6-Place each part as it is removed, in some systematic order, either in a parts box or on the bench.

7-Check up each part on re-assembling, and make certain that all nuts are tight.

To Remove Engine.

(Note—Have you got the common tools necessary to do the work right where you can get them instantly, or are you going to spend half your time running for them?)

1-Drain radiator.
(This will be draining while you remove the lamps.)

2-Remove lamps.

3-Remove radiator hose connections, brace, and retaining bolts.

4-Remove radiator.

5-Remove all wiring terminals marking each one as shown in fig. 1 so that they may be returned to the proper binding post.

6-Remove throttle and spark control, connecting steering post with engine base.

7-Remove oil pipe connections, and gasoline pipe, after turning off gasoline.

8-Disconnect exhaust pipe from manifold.

9-Remove torsion tube yoke pins from yoke.

10-Remove bolts from universal casing.

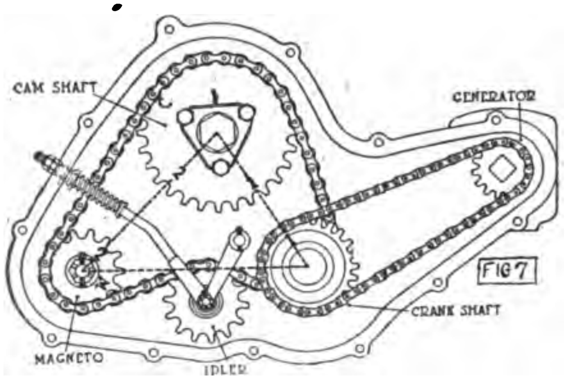
11-Remove fan belt and pulley retaining nuts on crankshaft flange.

12-Remove fan belt pulley on crankshaft, using special puller shown in fig. 2.

13-Using rope sling, and chain blocks, hoist engine forward, removing it from frame.

—see next page.

CHART NO. 258—Example of Fitting Main and Connecting Rod Bearings of Overland Model 75B—Continued in chart 259. (Motor World.)



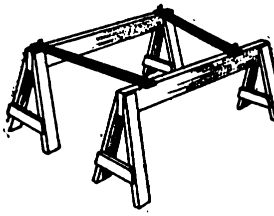


Fig. 6—Accessibility is essential in engine repair and necessitates some sort of a stand. After removing the crank case base and the cylinder head, the stand illustrated may be used to hold the engine upright or bottom up

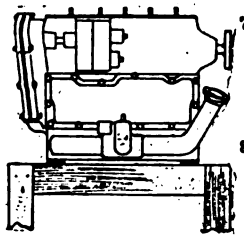

Fig. 8—Engine (bottom side up) bolted to horses.

—continued from chart 258.

14–Drop engine onto two horses, connected by iron straps, as shown in fig. 6.

15–Remove clutch spring bolts as shown in fig. 8.

16–Remove 8 bolts holding rear support to engine base, and take off entire assembly.

17–Remove clutch.

18–Mark flywheel and crankshaft flange with center punch, so that it may be returned as taken off. Remove flywheel bolts and flywheel.

19–Remove cylinder head.

20–Remove connecting rod bearings, marking both rods and caps so that they may be reassembled exactly as taken off.

21–Remove connecting rod and piston assemblies.

22–Turn engine bottomside up, and fasten to horses, as shown in fig. 8.

23–Remove timing gear case, exposing timing gear and chain.

24–Turn crank until front and rear throws are at top dead center. The distributor should then be making contact with No. 1 brush. If not, turn crank over once. Then mark face of gears as shown in fig. 7 if this has not already been done.

25–Using puller shown in fig. 5, remove crankshaft sprockets.

26–Remove front crankshaft bearing assembly bolts.

27–Remove rear crankshaft bearing assembly bolts, and draw crankshaft out towards the rear. (By careful inspection, get some idea of the actual amount of looseness in the bearings; then remove the bolts holding the halves together, completing the tearing down.)

The Repair.

(Note—The work of refitting bearings is tedious even for the best mechanic. Do not expect to fit one bearing in less than two hours, if it is badly worn; and do not be disappointed if the bearing seems to get worse instead of better at the start of the scraping process.)

1–Carefully file a small amount of metal from the face of each bearing cap. To do this, clamp the bearing in a vise and holding the end of a fine flat file loosely between the left thumb and forefinger, the right holding the handle, draw the file with the left hand across both edges of the bearing-cap, per fig. 8, page 648. Do not remove more than .002; try the bearing, and if still loose, file again.

2–Clean both shaft and bearing with waste, wet with gasoline.

3–Paint the shaft with a solution of Prussian blue and water. Allow to dry.

4–Clamp bearing halves together on shaft, and turn three or four times with the hand.

5–Remove. The high points in the bearing will be blue, and must be scraped down.

6–Again clamp the bearing to the shaft, and repeat blueing, scraping and testing, until the bearing is properly "spotted in." When spotted in, but litle of the bearing half will be untouched by the scraper. An equal amount of material must be removed from each bearing half; and when properly fitted, the shaft will register contact over practically three-quarters of each bearing half.

7–Replace bearings, after oiling, and be sure that they do not bind. A small amount of binding may be removed by poening down the caps of the bearing with a hammer. When right, the bearings should be free enough to be turned by hand without great effort.

8–Check up the alignment of each piston with its rod and bearing, by the use of a ground arbor and square, fig. 9, (page 649.) see also chart 257. With a micrometer or calipers, check up roundness of connecting rod bearing on crankshaft; and if out of round, the best practice is to send them to a specially equipped shop for regrinding.

9–Replace crankshaft and crankshaft bearings.

10–Replace flywheel, making certain that it is replaced exactly as removed.

11–Replace No. 1 connecting rod assembly, and remove shims, until bearing binds. (This assures that there will be sufficient material to permit scraping to a seat.)

12–If binding is excessive, and the crank cannot be turned, replace one pair of shims, after filing.

13–Clean shaft and bearing, paint shaft with Prussian blue, and proceed with scraping as with main bearing.

14–When bearing is properly spotted in, oiled and tightened, an even resistance should be felt when turning the crank. (First hard, then easy turning indicates a poorly fitted bearing or an oval crankshaft. Again check with calipers.)

15–Scrape and tighten each connecting rod bearing in turn, having the others loose while so doing. And be sure to follow the marking placed on the rod and bearing, so that each assembly is replaced exactly as it came off.

The Reassembly.

1–Make certain that all nuts are tight, and that all cotter pins are in place.

2–Soak every bearing with cylinder oil.

3–Replace sprockets on front end of crankshaft, using a lead hammer, brass punch, or wooden block.

4–Turn crankshaft until pistons 1 and 4 are at top dead center.

5–Turn camshaft sprocket until point (1), fig. 7, comes opposite point (1) on the main sprocket.

6–Turn magneto sprocket until point (2) lines up with point (2) on camshaft sprocket. Distributing brush should now be in contact with cylinder of No. 1 terminal.

7–Wrap chain around sprockets and fasten the master link.

8–Replace timing gear case. Use shellac in replacing gasket.

9–Replace fan pulley.

10–Replace fan bracket and belt.

11–Slide clutch into place.

12–Replace rear engine support and bolt into place.

13–Replace clutch springs, as shown in fig. 3.

14–Replace cylinder head. See fig. 10, page 649.

(Note—Carbon should be scraped out, and valves reground and adjusted first).

CHART NO. 259—Continuation of Chart 258. Fitting Bearings. (Overland.)

Size piston rings on Overland 75B., 3⅞"x⅛"; Overland 85 (first thousand cars) 4⅛"x⅝", after first thousand ⅛"x¼" size was used. See page 607 for other piston ring sizes.

—continued from chart 259.

15–Replace base. Use cork packing, and shellac only one side.

16–Swing engine back into frame.

17–Holding drive shaft up, slip universal into place. The block and tackle are required for this job, and at least two men are needed; one to guide the universals, and one to manage the engine.

18–Replace universal yoke.

19–Bolt universals together.

20–Bolt engine to frame—and make sure retaining bolts are tight.

21–Replace pedal mechanism, brake rods, etc.

22–Connect the exhaust manifold.

23–Connect oil and gasoline connections. Turn on gasoline.

24–Connect wiring terminals. Make certain that marks are followed.

25–Replace radiator and radiator hose connections. Use rubber cement on all joints.

26–Replace controls from steering column to dash.

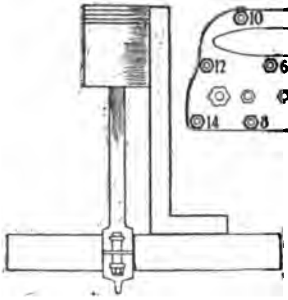
27–Refill radiator.

28–Place 9½ qts. of medium oil in base.

29–Spend 5 min. checking through all nuts, bolts, screws, pins, etc.

30–Start engine. Do not use starter, but crank by hand, or tow car while locked in high, if extremely stiff. If engine will not start after a reasonable amount of cranking, inspect wiring, gasoline and spark. But do not continue to crank blindly. When started, do not allow engine to race, but allow it to run slowly for a period sufficient to remove some of the stiffness.

31–Replace pan. 32–Replace hood. (from Motor World))



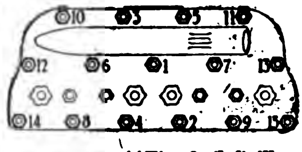


**Fig. 9 (left illustration). A ground arbor and a square should be used to check up the alignment of the connecting rod and piston assembly. This should be done both before and after scraping the bearings.

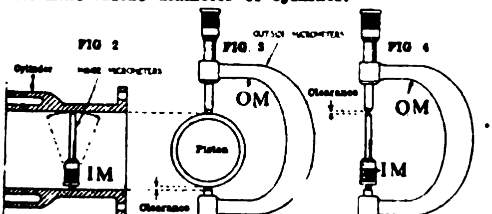
Fig. 10 (right illustration). In replacing the cylinder head, tighten the stud nuts in the order shown above. This will avoid warping or springing the cylinder head, and assure the tightest possible fit. No nut should be drawn clean down before all are set snug.

How To Measure ‡Piston and Ring Clearance.

Method of measuring piston clearance: Place "inside micrometer" (IM) in cylinder per fig. 2, and determine inside diameter of cylinder.



*Then place an "outside micrometer" (OM), over piston, per fig. 3, to determine outside diameter of piston.

Then place the "inside micrometer" (IM), fig. 4, as shown, in between the outside micrometer, and note the clearance.*** See page 651 for clearance.

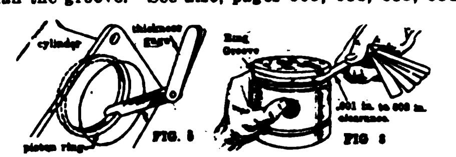
Method of finding ring clearance in opening of ring: Place piston without rings into cylinder. Then slip ring into cylinder behind piston, as shown in fig. 5. Pull piston up against ring in order to square ring up in the cylinder. If cylinder is worn it is usually at upper end, see "ring gap clearance," page 609.

A †thickness gage is then applied as shown in fig. 5 and distance determined. ‡‡As a general rule the clearance should be .004". per inch of cylinder diameter. This rule does not hold on patented rings as the Leak-Proof ring clearances are as follows:

2	to 3"	diam.,	.010"	opening.
3	to 4"	diam.,	.016"	opening.
4	to 5"	diam.,	.018"	opening.
5	to 6"	diam.,	.022".	opening.
6	to 7"	diam.,	.026"	opening.

This amount of clearance permits the rings to contract without the ends coming in contact, causing distortion and subsequent scoring.

To measure ring clearance in groove, see fig. 6. Remove all grit and see if groove walls are straight and not worn. The rings should fit freely into the grooves and should be from .001 to .002 narrower than the groove. See also, pages 609, 658, 659, 654.



Miscellaneous.

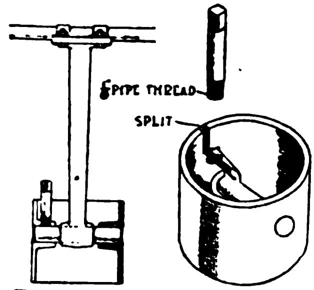


Fig. 12.

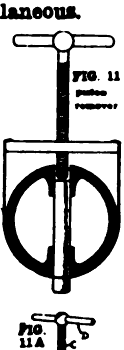
An expanding cylinder lap, made from a worn out piston. Head of piston is removed. One wrist pin bearing is tapped, then split piston as shown, so that a plug screwed into tap hole will cause piston to expand. An old connecting rod and handle is then provided. Ground glass and oil are used for lapping compound.

Fig. 12. Truing up valve tappets when worn, is shown in



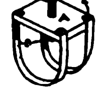


Fig. 11. Piston pin remover: A (fig. 11A) is flat iron tapped to take screw C. Flat iron bands are attached so they can be placed around piston, then pressure of screw forced against wrist pin (piston pin), see also page 650.

Fig. 13. Valve tappet guide puller made of short section of 2" iron pipe or any size larger in di. than guide. A washer is then placed over the top of pipe. A bolt which will go through guide hole and two nuts, will complete the puller.

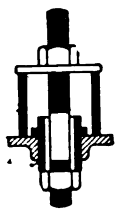

CHART NO. 259-A—Continued from Chart 259. How To Measure Piston and Ring Clearance.

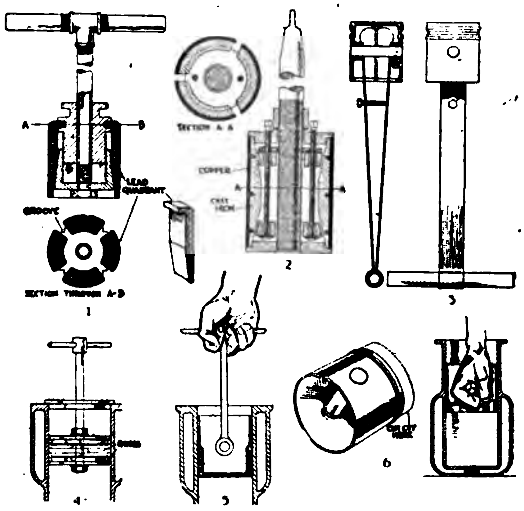
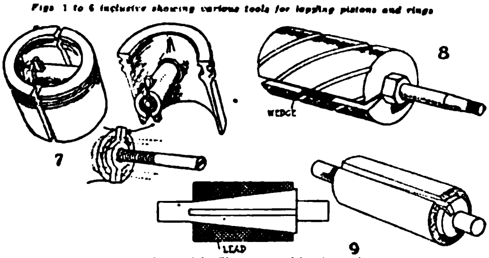
*See page 698 for explanation of a micrometer. **There are three disalignments possible in piston and connecting rod: Off-set in direction of crankshaft; bent to right or left in direction of crankshaft; a twist in connecting rod—see also pages 659, 646. †See pages 699, 697 for Thickness Gage explanation.
‡‡Ford ring gap clearance: Top ring .004 to .008"; center ring not over .012"; bottom or oil ring .016" since it is necessary that a small amount of oil work up between piston and cyl. wall. ‡See page 651 for "average piston clearance." ***This clearance can be measured with a thickness gage, per page 699.



Figs 1 to 6 inclusive showing various tools for lapping pistons and rings



Figs. 7, 8 and 9—Three types of lapping tools

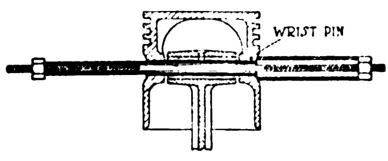


Fig. 22—For removing piston pin or bushings, a rod is turned to slide freely through bushing and then threaded S. A. E. standard. The pulling bushing is made slightly smaller than hole in piston, see also, page 649.

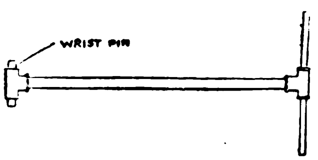

Fig. 20—Another piston lapping handle: When it is desirable to lap a piston of a detachable-head engine without removing the cylinder casting, the tool shown is a time-saver. It is made of ordinary ½-inch pipe, a T at the lower end slipping over the wrist-pin of the piston. The wristpin used in lapping should be made of fibre, as a metal one is likely to score the cylinders. Ground glass and crocus mixed in equal parts is used at the finish and ordinary valve grinding compound at the start.

Lapping Tools.

Fig. 2 shows a simple design of an expanding lapper. Such a tool as this may be used in the drill press, an up and down and rotary motion being supplied at the same time. Fig. 1 shows another tool of this type. Its construction is readily understood.

An expanding piston lapper which may be used for lapping rings or cylinders is shown in fig. 3. The two operations should not be simultaneous, however. When the cylinders are slightly scored, the marks should be removed first and then the new rings should be lapped in.

When no piston is available the rings may be lapped between two blocks of wood as shown in fig. 4.

Rings may be placed in an old piston. A new piston should not be used because it will wear away to some extent and this is objectionable. Fig. 5 shows how the lapping is accomplished. Another method is to cut off the head of the piston and use the wristpin for a handle, as shown in fig. 6.

Fig. 7 shows a simple expanding lapper made from an old piston. A piece of tubing is brazed into one piston boss and another tube to fit snugly inside of it is brazed into the other boss. The two halves are kept in line by slotting the two tubes and inserting the member shown at the bottom of the sketch in these slots. Adjustment is obtained by screwing out on the screw as illustrated.

Fig. 8 shows how a cylindrical block of wood, closely fitting the cylinder bore, may be used when an old piston is not available. Emery and oil are put on the cylinders and the lapping proceeds in the ordinary way. Grooves are cut in the surface to aid in the distribution of the abrasive. Adjustment for wear is provided by a slit which is opened by a wedge.

Fig. 9 consists of a tapered arbor over which is placed a lead sleeve; the position of the sleeve determining the exact diameter of the tool. The arbor has a key which prevents slipping. The sleeve is cast in place and then the slot is cut to receive the key. The expansion of the tool is accomplished by driving it further up the arbor. Reduction in size is obtained by moving it in the opposite direction and compressing it.

Lapping Pointers.

If the cylinder surfaces are in good condition only the rings need be lapped. The purpose in lapping the rings is to make them fit tightly against the cylinder surfaces.

The lapping process consists in moving the rings back and forth in the cylinders in the presence of a mixture of ground glass and cylinder oil, or carborundum and cylinder oil.* The abrasives should be the finest obtainable. (see page 658.)

When the rings bear all around, the work is finished. This can be seen with naked eye.

If the cylinders are slightly scored they should be lapped with an old piston. It is not desirable to use a new piston because it will be worn away and for the same reason new rings should not be used in the piston during the lapping process.

If cylinders are badly scored an old piston with old rings should be used and after all marks are removed the new rings should be lapped in place, using an old piston.

When the cylinders are badly scored an expanding lapper may be used instead of the old pistons. (see page 649.)

Aluminum pistons cannot be treated in the same way as cast iron because they are too soft. High spots on the pistons may be removed by means of a semi-cylindrical brass lap shown, into which the piston fits.

Removing a Cam Shaft—Dodge as an example.

To remove the camshaft the radiator must be taken off and then the front gearcase cover. The camshaft may then be pulled out after the valve push-rods are tied up so as not to catch the cams as they slide by, and after the camshaft retaining pin (which will be found on the right side of the motor directly back of the ignition unit) has been removed. This pin fits in a deep groove in the center journal. In the first 40,000 or 50, 000 cars the pin was held in place by a setscrew, but the newer cars have a spring.

CHART NO. 259-B—How to Lap Pistons and Piston Rings.

*Another lapping compound for piston, rings, etc., is engine oil or coal oil and flour of emery. For a very fine finish use valve grinding compound secured at supply stores. It is often made of crocus which is finer than emery and is usually used on razor straps. The best compound for this purpose is the Clover Lapping Compound—see foot note, page 630 and write for free pamphlet.

—continued from page 645.

67 per cent. This cuts down side pressure or thrust on the walls of the cylinders and reduces friction and the consumption of lubricating oil. The great heat conductivity of aluminum alloy lessens the carbon deposit on the piston head and the deposit is more easily removed. In case of extreme heat it is claimed the lynite piston will not "score" or cut the cylinder walls. It is a proven fact, that the lighter the piston the quicker it will operate, therefore greater speed and flexibility is the result.

***The main drawback however, is the "slap"** which often occurs as explained on page 637, unless the pistons fit or the clearance is exact. When cold, the clearance of an aluminum piston is considerably more than cast iron, therefore until engine is warmed up there is more or less slapping noise. As the heat increases however, the piston expands and the noise disappears.

The writer knows of one instance where the lower part of an aluminum piston which had a tendency to slap, was grated with a file, like a nut-meg grater, this reduced the noise to a considerable extent, due to the fact that the clearance space was reduced by the roughening process.

**Piston Clearance.

A piston does not fit the cylinder wall tightly, if it did, it would **seize** and stick when it was heated, as it expands with heat.

The piston rings fit tight however, but being split and of spring tension, they fit the cylinder at all points—or at least they should. For this reason clearance must be allowed between the wall of cylinder and piston, per measurements below.

†Cast iron pistons require about ½ the clearance than those made of aluminum alloy, because they do not expand so much under the same degree of heat.

More clearance is required at the top because here the heat is greatest, therefore greater expansion.

If pistons are fit very close to cylinder it will run very quiet but may heat and stick and cause engine to slow down or stop if driven at a high speed. In fact all new engines should be driven at moderate speed for the first 1000 miles—see pages 203, 489, 655.

If pistons are fit moderately loose, they may "slap" until heated up, but this will hardly be noticeable if kept well oiled—regardless of hard work or fast running. The practice is to give greater clearance for higher speed.

The clearance of cast iron pistons is usually graduated, for instance, refer to fig. 24. The piston is ground straight from the skirt bottom up to the top of D, as shown at L.

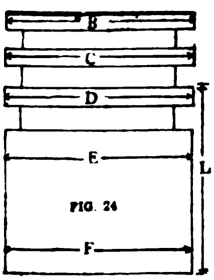

FIG. 24

This part is ground so as to allow approximately .001" clearance for each inch diameter of piston.

From D to C it is relieved .004" additional; from C to B, .012" in addition to the ground diameter of the lower part of piston.

†Lynite (aluminum alloy) pistons should be given twice the clearance as cast iron. Semi steel pistons (seldom used in auto work) **expand slightly more than** cast iron.

Questions on Pistons and Rings.

(Q1) How many rings are generally used?
A—3 or 4.

(Q2) How many rings are generally used on racing car engines?
A—1 or 2. (See reason on page 587).

(Q3) What clearance should cast-iron pistons have on an average?
A—.001 per inch of piston diameter.

(Q4) What clearance should aluminum-alloy pistons have on an average?
A—.002" per inch of piston diameter.

(Q5) What is the method for **reboring** cylinders?
A—See pages 653 and 654.

(Q6) What is the difference between concentric and eccentric piston rings?
A—A concentric ring is one of equal thickness throughout its entire circumference. An eccentric ring is not.—At a point (e, fig. 2, page 655), opposite the split in ring, it is made thicker.

(Q7) What is the advantage of eccentric rings?
A—Unless a piston ring bears with equal tension on the cylinder wall at all points of its circumfrence, the compressed gas would pass at the point where it did not bear and thus leak compression. A ring is subjected to considerable heat, at which time it may loose its tension at some point of its circumference. Some claim by making a ring eccentric, it will retain its tension under heat more so than a concentric ring.
Others claim that if a concentric ring is made of the proper material it will retain its tension. Most all of the patented rings are concentric, in fact the majority of plain rings (fig. 5 and 6, page 655) are concentric. Sometimes two concentric rings (patented type) are fastened to each other so as to have the split diametrically opposite each other, as per the Leak Proof, page 655. The Inland (see pages 655, 609) is a one piece concentric ring with a long lap. Some advantage is claimed for concentric rings over eccentric rings, for instance, the carbon that accumulates back of the ring will tend to lock an eccentric ring sooner than a concentric ring, thereby preventing the natural shifting of the ring around the piston grove.

(Q8) Are all pistons fitted .001" per inch piston dia.?
**A—No, one concern state that they give .002" to .003" clearance to passenger car engines; .003" to .004" to truck engines and .004" to fire apparatus engines, regardless of diameter. Where engines run for long periods under full power they require more clearance than others.

(Q9) What troubles result from too loose a piston?
A—In addition to a "slap" and wear of cylinder wall, the gasoline will pass into crankcase and thin the oil, thus injuring the bearings. Will also pump oil, causing carbon and smoke.

(Q10) What is meant by "squaring" the piston?
A—When fitting pistons in cylinder, if the cylinder blocks are not lowered carefully, the connecting rods will be slightly bent, or if in scraping a bearing, one side is higher than the other the piston will set at an angle. It is very important that pistons be in perfect alignment—see pages 659, fig. 3, and 646, fig. 1.

(Q11) What are pistons usually made of and what is meant by "seasoning" and "heat-treating"?
A—Pistons are usually made of cast iron, then not machined for a long time, to allow it to set so it will not change its shape, or not contract so great when cold and expand so much when heated, thus permitting maximum clearance, to reduce slapping when cold. Heat-treating is supposed to have the same effect as long seasoning.

(Q12) How are pistons machined?
A—They are turned down to within .005" of size, then ground to exact size on a special grinding machine. On high grade engines the pistons are seasoned or heat-treated then turned and ground to fit each cylinder individually. On some of the cheaper grade engines they are not always heat-treated or seasoned and are made in quantities and the assembler fits the pistons to cylinders as they come.

*See page 638, fig. 7, for Franklin method for remedying aluminum piston slap. The Sterling engine (used on the Scripps-Booth, which has aluminum alloy pistons) has a strip of piano felt placed under the lower piston ring. Manufacturers of aluminum alloy pistons: Butler Mfg. Co., Indianapolis, Ind.

†Varies with different manufacturers, see also page 649.

**The amount of clearance depends upon the speed of engine, efficiency of cooling system, type of water circulation, length of water jacket. If engine is "hot-running" or heats quickly, clearance is increased proportionately. If "cool-running," give less clearance. It will vary, depending on above conditions—see also page 649 and foot note, page 653. Ford piston is .010" smaller at head than skirt and should have .003" clearance—see also, page 791. Air cooled cylinders usually expand outward, which equalizes with the expansion of piston. Therefore the same ratio applies. See page 609 for fitting "oversize pistons".

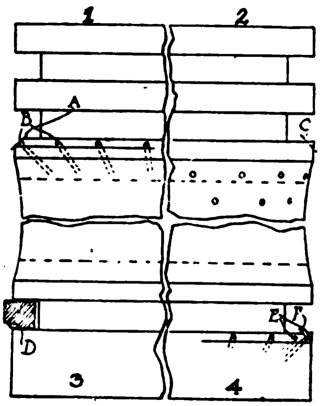

Fig. 6—How to remedy spark-plug fouling from use of too much oil. For convenience the drawing has been divided in quarters to be designated as 1 2, 3 and 4.

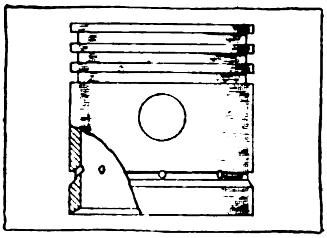

Fig. 8—Another suggestion: To cure excessive lubrication to which some old cars are subject to, the pistons should have a narrow groove turned in the skirt with the lower edge of the groove beveled. With a No. 30 drill about six holes are drilled at equal distances around the piston and at an angle through the groove The sharp edge at the top of the groove acts as a scraper and the surplus oil passes through the drilled holes, returning to the crankcase. No ring is placed in the slot. see chart 286-A, and page 202.

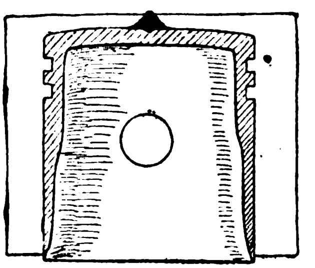

Fig. 9—The collection of carbon on the top of the piston head is often greatly accelerated by the lathe center mark in the head, and where possible this hole should be avoided or filled up. It is the starting point at which the carbon begins to collect and soon there is a mound at this point. The rapidity with which carbon collects can be greatly reduced by smoothing the walls of the combustion chamber, especially the top of the piston. The surfaces should be polished with emery and crocus cloth.

Remedying Excessive Oil with Piston.

At 1 fig. 6, at A, is shown a popular method for overcoming some of the troubles due to an excess of oil. Note the chamfered lower edge of the second ring groove, B; 1-32-inch holes are drilled from the chamfered edge to the inside of the piston. This is for return flow of the excess oil. An extra large hole in each side over the piston pin bearing and running into same will improve its lubrication and insure long life. The number of small holes around the chamfered edge should be determined by the extent of the fouling.

At 2 is shown the chamfered lower edge of the second ring groove and the small holes drilled through piston in the recessed space about the middle. Here, as at 1, the number of holes should be determined by the extent of the fouling.

At 3 is shown the chamfered lower edge of the bottom or oil ring. This very simple method is highly successful, a great deal easier to perform and is the one employed in the repair shops of the various Ford branches.

At 4 is shown the method employed in 1, as applied to the lower ring. Ford pistons before the latter half of 1918 did not have this lower oil ring, therefore the ring wear and travel is limited to the space covered by the three top rings. Since this leaves a space a couple of inches high at the bottom of the cylinder which remains smaller than the top, it will be seen that over-size pistons that will fit the top will not go through the bottom of the cylinders and if it is desired to cut these in it will be found necessary to lap them in. Lapping should be done with an old piston, the rings left in and pinned to keep them turning with the piston. Lapping is best done by power under a drill press with a dummy rod tapered to fit the press. The piston should be rotated and raised and lowered twenty-five to thirty times per minute.

Oversize pistons are not needed where any of the above methods for correction of fouling are used—their only function in such cases being to lessen the noise from piston slap. It is safe to say that a set of cylinders which offer objectionable noise from piston slap have been neglected in the matter of lubrication or are very old in service and in such cases the connecting rod bearings are always out-of-round in direct proportion to the wear of the cylinders and it will be found impossible to keep these rods tight and thus do away with the noise, loose rods occasion. (see also page 202.)

Cause of Smoke and Indications of Color.

If the vapor is black and foul smelling it is caused by too rich a mixture (too much gasoline); this can be remedied in carburetor.

If the smoke is white or blue, the engine is supplied with an excess of oil.

If smoke is gray, there is too much fuel as well as a surplus of oil.

The reason an engine excessively supplied with oil smokes is that if there is too much in the crank case the entire lower portion of connecting rod will dip into it and the lubricant will be forced into the cylinder to work by the rings on the piston, then into the combustion chamber. If there is surplus of oil, more than what is needed, then a remedy is to chamfer and drill holes as shown in fig. 6, and 8 (also page 202) these having a right angled edge at the top side and sloped toward the base, so as to scrape the oil from the walls on the down stroke.

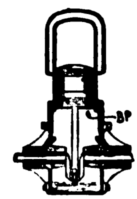

Fig. 10

Another method formerly used was a baffle plate as shown at BP in fig. 10. This is a simple plate of sheet metal in which a slot is cut, through which the connecting rod works, thus preventing an excess amount of oil finding its way into the mouth of the cylinder.

If spark plugs are constantly oil soaked, this indicates leaky piston rings. The oil passes the rings, hence the cause. It can also be caused by the "piston pumping" oil as explained on page 653 and below, even though ring is a good fit.

Vacuum Cause of Piston Pumping Oil.

When you see blue smoke issuing from the exhaust it indicates too much lubricating oil is being consumed.

If this occurs regular at all speeds, it is generally due to piston rings.

If only occurs when engine is run at low speeds for long periods, or idling at the curb, it is due to either cause as follows:

When engine is run fast a vacuum is not produced in the cylinder, because so much gasoline and air is drawn into cylinder.

When engine is throttled down only a little air is allowed to enter, therefore more of a vacuum is produced. The tendency being for the vacuum to suck up oil from crank case past the piston rings.

You no doubt have seen many a car start off from a standstill after the engine has been running slowly for a time and watched clouds of smoke coming from the muffler. Gradually, as the car gets under way the smoke gets less and finally no smoke is evident, unless the mixture should be too rich, in which case the smoke is black.

CHART NO. 260—Piston Relation to Smoke and Excess Oil—Cause of Smoke and Color.

See also, page 202, 793.

Relation of Piston and Rings to Smoke and Excess Oil.

This subject is treated in chart 260 and below. Note that while rings may be in good condition, yet it is possible to pump oil past them by action of the piston. This is very common on some engines.

*Piston Pumping Oil.

Quite often the combustion chamber will be constantly oil soaked, thereby keeping the plug fouled and cause missing. The front or rear cylinders are prone to this and it appears that it is due to the fact that a necessary amount of oil must be carried in the crank case and when car is going up or down hill the rear or front cylinders get an excessive amount of oil and the piston assists by pumping it past the rings. This is common where there is excessive clearance, especially in old engines and quite often in new ones, where there is excessive clearance to begin with and poor fitting rings in addition.

Another common cause—is too high an oil pressure. It is by no means unusual to see pressures of 30 lbs. employed.

Very few people are aware of the fact that the piston and cylinder walls in a well-designed engine should not be placed in the actual path of the big-end splash.

At ordinary engine speeds the inside of the crank case is in a condition of what can be aptly described as "oil fog," and although all the crankshaft bearings are fed directly with liquid oil, the cylinder itself should be supplied by "fog" only, which is much denser than one might imagine and quite equal to its work in this respect.

Any actual splash which gets on the walls simply leads to waste and carbonization through the oil getting past the rings into the combustion head and being burnt.

Another method adopted by many, is to taper off the top of piston so that the oil instead of gathering on the head will gather in the space around the outside diameter between piston and cylinder walls, where it does the most good.

A third cause of oil waste is to be found in the piston rings.

If worn slightly oval they will cause leakage if their position is not rigidly maintained.

It is always advisable, therefore, to pin them, and the best way to do this is to drill and tap the center of the ring groove and screw in a fillister headed peg or screw; this head is now filed in half and one of the steps of the ring lengthened to accommodate it. The edge of the step prevents the peg unscrewing, and a very permanent and satisfactory fixture is assured.

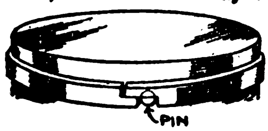

Fig. 8—A pinned piston ring.

Under racing conditions, where the piston is a very slack fit and a minimum of friction essential, a slight advantage in engine speed is obtained by using a surplus of oil, for it is well to explain that in describing these various methods of reducing oil consumption the ideas aimed at are (1) economy and (2) prevention of rapid carbonization. It is not intended to convey that any actual mechanical harm is done to the engine by over-oiling.

Remedy.

Where there is excessive clearance a good plan is to make the ring act as a scraper and beveling off the edge of it's groove as explained on page 652.

The lower and exposed edge of the ring catches the oil during the down stroke, and forces it through the holes back into the crankcase again.

**Cylinder Reboring, Reaming and Grinding.

When an engine runs without oil, the cylinder wall may become scratched or "scored." (see page 202 and 609).

In fact, cases have been known where cylinder was getting plenty of oil, yet rings being loose, the flame from combustion would work past the loose ring and prevent it from receiving proper lubrication, causing it to heat and cut cylinder.

Cause of a scored cylinder is frequently due to a loose piston pin, which scores, or cuts cylinder wall, thereby permitting a leak between wall of cylinder and ring.

**A scored cylinder can only be remedied by reboring, reaming, or grinding and this is a job that ought to be done where a special reboring or regrinding machine is installed. When a cylinder is enlarged, oversize pistons and rings must be fitted, (p. 609).

If cylinders are not scored too deep they can be lapped in with an old piston covered with oil and emery, per pages 650, 649, or scores can be filled, if cylinders are not out of round.

The first troubles caused by worn or scored cylinders are fouled spark plugs and excessive carbon deposits due to oil leaking past the piston and rings, compression also escapes by the worn parts, causing loss of power and wasting gas and oil. A very annoying knock or clatter known as "piston slap", soon developes. The longer the engine runs the worse this condition becomes. An engine in this condition is not only wasteful but also very noisy.

†S. A. E. Standards for Oversize Pistons.

There has hitherto existed no uniform practice as to the amount of metal removed in regrinding worn cylinders, with the re-

†The S. A. E. has never adopted any standards for piston clearance because the difference in materials, in cooling, and design of both pistons and cylinders, affect the amount of clearance necessary, see foot note, page 651.

*See also "vacuum cause of piston pumping oil," page 652. **There is now a process of filling up cylinder scores with copper or solder, thus saving time of reboring, etc. This process is quite satisfactory if the score is deep enough so it can retain the filling, for instance, over $\frac{1}{16}$" deep and cylinder is not out of round—if under this, then cylinder should be ground, or if very slight and cylinder is not out of round they can be lapped. Write H. & H. Machine Co., St. Louis, Mo., for an instructive pamphlet on grinding.

sult that difficulty is experienced in securing new pistons of correct size, from the manufacturers.

With a view to eliminating all unnecessary expense and delay, the **following standards have been accepted by the society** and can be obtained from most engine manufacturers.

10 thousandths inch (.010") large for 1st
20 thousandths inch (.020") large for 2nd
30 thousandths inch (.030") large for 3rd
40 thousandths inch (.040") large for 4th

The meaning of 1st, 2nd, 3rd and 4th is this; if cyl. is scored or cut, say .009 inch deep, then bore it to fit a .010 inch oversize piston. If cut .011. then bore it for a piston .020 inch—but not between the two. In other words quite a number of auto manufacturers furnish pistons larger than their standard product by increments of .010 inch, thus making it possible to regrind scored or worn cylinders to these S. A. E. standards and procure pistons from stock.

Questions On Enlarging Cylinders.

Q1–When should a cylinder be enlarged?
A–When it is out of round more than .003" or when cut or scored.

Q2–How can you tell if it is out of round?
A–By measuring with an "inside micrometer" per page 649.

Q3–Suppose it is not out of round but cut, should it then be enlarged?
A–No; it can then be "filled" as per foot note, page 653, also page 609.

Q4–How much should it be enlarged if out of round?
A–Enough to have it perfectly true. See also, top of this page and page 609.

Q5–How is a cylinder enlarged?
A–By grinding, boring, reaming, or lapping.

Q6–Which is the best?
A–Grinding. To grind a cylinder however requires a very expensive equipment, at least $2,000. Boring, on a special boring machine is next best and the equipment is very reasonable. See fig. 2, page 615. Reaming is third best, lapping would come fourth. See page 650 relative to lapping.

Q7–How is a grinding machine operated?
A–Grinding is done on a special grinding machine, employing a wheel made of abrasive material revolving at a high rate of speed on the end of a rigid spindle. The spindle at the same time moves in a circular path so that the revolving wheel travels around the hole. The path of the spindle is adjustable to the diameter of the hole. The cylinder is held stationary and a multiple cylinder block can be ground without moving it, thus insuring that all cylinders are perfectly round, smooth, straight and square with base of cylinder casting. Grinding gives a true smooth surface and no matter how hard or soft the material the grinding wheel will grind it just the same. A lathe tool cannot leave a cylinder as smooth as a grinding wheel.

Q8*–How are cylinders bored?
A–By placing in a lathe; by placing in a drill press; by placing in a special boring machine.
When placing a cylinder on the face plate of a lathe a long boring bar is used. The cylinder, unless clamped securely will move and ruin the job. Other disadvantages are that the long boring bar is likely to vibrate or jump and slide over a hard spot without cutting. Furthermore, the cylinder must be moved and reset on the face plate, if a multiple cylinder block, thus requiring skill to bore each cylinder straight with its base. A lathe tool cannot leave a cylinder as smooth as a grinding wheel. When placed in a drill press, this is better than on a lathe, as the cylinder does not revolve, and can be held more securely, but otherwise there are the same disadvantages. When placed in a special boring machine the work can be done better than on a lathe or drill press, as the cylinder is held securely in place and the boring bar spindle is very heavy and rigid.

Q9–How are cylinders reamed?
A–Cylinders can be reamed on a drill press (see fig. 65, page 792), or by a small reaming outfit which can be attached to a cylinder block. The disadvantage of reaming, to enlarge a cylinder, is the tendency for the reamer to follow the course of the old hole, thus preventing it from making a new and perfect hole. It is also necessary to take a deeper cut than would be necessary if grinding.

Q10–Is it necessary to fit larger pistons when a cylinder is enlarged?
A–Yes, oversize pistons must be fitted as per page 609, also oversize rings fitted to piston.

Q11–Would you advise sending cylinder to a specialist to regrind and do you advise having the entire block reground?
A–Yes—see page 651, 609. If you wish a perfectly balanced engine it is best to have the block reground, especially if engine has been run 20,000 to 30,000 miles. Also have oversize pistons ground to fit each individual cylinder. The H. & H. Machine Co., St. Louis, Mo., are fully equipped for this work. Read answers to Q12, 11 and 10, page 651. See also, page 609.

Q12–What are the symptons of a worn or cut cylinder?
A–Lack of power, heavy fuel and oil consumption, smoke, fouled spark plugs, and a piston slap. See answer to question 9, page 651, which is a similar trouble. See also, page 609.

Q13–Where do cylinders usually wear?
A–In the space where the rings travel. If piston is loose, then the constant pressure from explosion force will wear the cylinder on one side, near the top, due to the piston striking the cylinder wall at an angle.

Q14–Isn't it possible to fit oversize rings to a worn cylinder?
A–Yes, but it is not altogether satisfactory because the wear is usually where the rings travel and in order to fit the rings, they must go in at the open end which is not worn. In this instance the rings are filed at the gap so they will pass the lower part, then they open up at the point where cylinder is worn. If cylinder is oval, then no round ring can fit it true.

Q15–Is it advisable to lap oversize pistons to a worn cylinder?
A–The piston or lapping tool is sure to follow the old hole, thus while lapping may improve conditions, it is impossible to make the cylinder perfectly round, if it is out of round. If cylinders are perfectly round and pistons are two small then oversize pistons can be fitted.

Q16–Are all high grade engine cylinders ground?
A–Yes, and heat-treated, or seasoned castings used and ground pistons fitted to each individual cylinder. Most all cylinders, when new are first bored to within about .005" of size and then ground. Read answer to Q12, page 651.

**Piston Rings.

A piston must be fitted with piston rings. The piston is slightly smaller than the bore of the cylinder (page 651), in order that it will not stick to cylinder wall (call seizing), when it becomes hot and expands.

Ring grooves are provided on pistons for the rings (see fig. 4 and 6, page 74). The grooves are slightly wider than the ring. For instance, the Ford ring is 1/4" wide and the width of the groove is one and one half thousandths wider (clearance). On the Dodge, the ring is 3/16" wide and groove has a clearance of one and one half thousandths. See also, page 649.

If a ring groove becomes worn, and is over .005" clearance then the piston can be put in the lathe and groove widened to take a 1/32" oversize width ring.

Depth of grooves average about 3/16". The average **thickness of a ring** is 5/32", thus there is 1/32" deeper groove. On some of the V type engines the grooves are shallow. The rings are about 1/8" thick and groove depth is about 1/32" or 1/64" more.

If the groove is too large there will be a compression leak between the groove and the ring. If two narrow, the ring will stick in the groove and not exert its tension against cylinder wall.

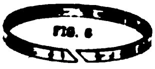
The ring gap is provided on all rings in order that it can be fitted to the piston groove and so it can expand and exert tension against the cyl-

*A **re-boring attachment** can be secured of the South Bend Lathe Works for use on South Bend Lathes of 16 inch and larger size. A circular descriptive of this attachment can be secured by writing to the South Bend Lathe Works, South Bend, Indiana—if you mention this book

****The size of piston rings used on leading cars** is not mentioned in this book, but the diameter of bore of cylinder of leading cars is given on pages 544 to 546 and the size of rings for some of the older model cars is given on page 607. Some of the piston ring manufacturers supply lists of sizes.

inder walls. There are several kinds of ring gaps for instance, see fig. 5 and 6. Fig. 5 gap is called a "step-joint" gap and fig. 6, a "mitre-joint" gap. Another kind of joint is shown on the Inland, page 609 and this page, which is a long "bevel lap joint". There are many other kinds of joints or gaps used on the various patented rings. The step-joint is used most.

Step-cut ring



Mitre-cut ring

When the ring is in the cylinder, the gap clearance is very slight (see page 649), otherwise, if it were too great, there would likely be a leakage of compression through the gap, or if all of the gaps were in line, when in cylinder then it is likely that there would be a leakage of compression from combustion chamber to crankcase through the gaps and inasmuch as the rings are free to work in their grooves, the common belief is that the rings move, or work around in the grooves until they are all in line at one time. However, this is improbable as well as probable, for if the rings thus work around, they are likely to continue working and if originally placed on the piston equal distance apart, (see page 659), then there is not much chance for all of them to get in line at the same time.

Before the advent of the patented ring, the rings were pinned, that is, the gaps were first placed 120° apart on the piston and then the ends of rings were notched with a fine round file, so that the semi-circular notches just closed over the pins (see fig. 3, page 653). The pins were a source of nuisance in high speed engines and unless great care was exercised in screwing or fitting the pins tight into the piston, they would loosen and project and cut the cylinder wall, thus this practice was abandoned to a certain extent. Pins are still used on many large, slow speed engines and on two cycle engines. There is no doubt but what the pins had the advantage of insuring against their getting in line as well as having disadvantages. The growth of the popularity of all kinds of patented rings with gas type joints has thrived on this claim as well as the claim that the patented ring exerts equal pressure at all points of its circumference. For instance, note the long lap of the Inland ring and the construction of the Leak Proof ring.

It is important that a piston ring exert equal pressure or tension against the cylinder wall at all points of its circumference and right here is one of the most important duties of a piston ring. If it fails to do this, then the part of the ring which does not press against the cylinder wall is bound to permit the compressed gas to pass into the crankcase.

The concentric ring (fig. 1) is one of equal thickness throughout its entire circumfrence.

The eccentric ring (fig. 2) is made eccentric (thicker), at one point, as shown at e.

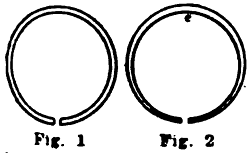


Fig. 1 Fig. 2

Some manufacturers claim that the concentric ring will maintain equal tension under heat, if made of the right material and others claim that the eccentric ring is the best—see Q7, page 651.

A very popular step-cut concentric ring is the "hammered ring", made by the American Hammered Ring Co., Baltimore, Md. This ring looks very much like the one shown in fig. 5, except the inside of ring has been hammered or peened, with hammer marks. The makers claim that this operation causes the ring to have equal tension at all points of its circumference. This make of ring is used on the Buick, Dodge, Pierce-Arrow, Locomobile and Stutz engines. **Another peened ring** is made by the Wasson Piston Ring Co., Plainfield, N. J.

The average life of a plain piston ring is about 10,000 miles. A piston ring is made of slightly softer metal than the cylinder.

There are usually three piston rings above piston pin and quite often an oil groove is in the skirt of piston. On many engines, there are three piston rings above the piston pin and one ring below the piston pin. On the Ford, there are two piston rings above the piston pin and one below. See p. 791, fig. 17, and note how the Ford rings are tapered in order to prevent an excess of oil getting to the combustion chamber.

The ring below the piston pin is for two purposes: (1) To prevent piston slap; (2) to keep oil down and is often called the **oil ring.**

Therefore, we might term the rings above the piston pin, the "compression rings" and below, the "oil-ring". The oil-ring is usually given slightly more clearance at the gap,—see foot note, page 649.

If piston pumps oil and the spark plugs are constantly oil soaked, then the oil-ring should have holes drilled in the groove behind the lower ring, as per pages 652, 202.

On these pages, it will be noted that the oil holes are in the ring groove above piston pin as well as below. The practice is to first drill holes in ring groove below piston pin and if this does not relieve the excess oil to combustion chamber, then do the same with first ring above the piston pin.

When fitting new rings to a piston be sure that all the other cylinders have good compression, otherwise, the cylinder with good compression will have a rich mixture and those with poor compression, a leak mixture with result engine will not idle properly.

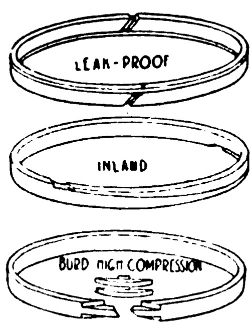
When fitting rings and pistons, be sure that ring grooves are clean and that piston is perfectly round. If piston is slightly oval, squeeze it in a vise, the jaws of which are covered with copper or lead, or tap piston gently with a rawhide mallet or wood.

Before putting cylinders on, see that the piston pin set screws are tight; put oil on piston; see that piston and connecting rods are in alignment as per pages 659, 646.

After completing the job, put plenty of oil in crankcase; enough so that not only the oil pan will be full, but enough above oil pan so connecting rods will dip. Connect radiator with hose so water will run through (see page 793); run engine slowly for two or three hours. Don't race engine. Then run car, not over 15 or 20 m. p. h. for the first 500 miles—use plenty of oil.

Patented Rings.

Patented rings are made in many different constructions. The primary object is to produce a ring which will have a gas-tight joint and exert equal pressure at all points of its circumference. The "Inland" is a one-piece ring, whereas the *"Leak-Proof" is a two-piece ring. Other popular patented rings are the "Gill" and the "Double Seal", in fact, there are a great many different makes of patented rings.



Effect of Leaky Piston Rings.

If rings do not fit the cylinder wall with equal tension at all points there will be a loss of compression and a smoky exhaust—see pages 626, 628, 629, 653, 656, 202.

If the rings are exerting equal tension; they will be smooth and shiny, as will also be the cylinder walls.

If the rings are dull and there are spots in streaks on them, it will indicate that the flame from the combustion passes between the piston

*The McQuay Norris Co., St. Louis, Mo., manufacturers of the Leak-Proof ring, also manufacture an oil ring called the "Superoyl". A small oil groove, or reservoir is cut around lower edge of this concentric ring, providing a scraping edge. One "Superoyl" ring is placed in top groove of piston and two Leak-Proof rings below, in cases where an excess of oil reaches the combustion chamber.

rings and cylinder wall, leaving a sooty deposit, as will also the compression pass, reducing the power of engine.

Causes of Leaky Piston Rings.

(1) **Rings sticking in their grooves** because of gummy deposit from lubricating oil; rings that are stuck in their grooves will usually not press against the cylinder walls, (2) rings may have become **broken**, (3) the joints of the rings **may be in line** allowing the compression to escape, (4) **rings** may be **worn or cut** from lack of oil, (5) rings may not be **wide enough** for the grooves, (6) the oil pressure may be **too** great and oil of **too thin** a body **used**.

Testing Piston Rings and Cylinder for Leaks.

In order to find out if the rings leak, try the piston and see if the gas is escaping through the rings into the crank case. This can best be accomplished by removing the lower part of crank case, after which turn the crank so that the piston makes its compression stroke, and listen for a bubbling sort of hiss in the crank case. Test each cylinder separately by opening the relief cocks in the cylinders not being tested. First determine which cylinder it is that is leaking. There is no mistaking this sound, since the crank chamber acts as a resonator, and even the slightest leakage is distinctly audible (also see page 629).

If the sound of gas escaping past the piston continues for an appreciable time (upward of a minute or so) the chances are that the use of an oil of slightly heavier "body," for cylinder lubrication, will cure the fault.

However, if the escape is of short duration, the matter is more serious, involving as it may a cracked piston, scored cylinder walls, or broken, warped or gummed rings.

If this is suspected, flush out the cylinder combustion chamber with an oil-gunful of gasoline, making no attempt to fully remove the liquid. Again put the piston on lower dead center, and with the aid of an electric lamp and a small mirror, observe the bubbles caused by the escape of the gas about the lower edge of the piston. There will naturally be no bubbles at this point, if the piston head is fractured, but it may be possible to see the crack through which the leakage occurs. At any rate, if enough gasoline has been left in the cylinder, one will be able to see it trickling down the connecting rod or inner piston walls, should such a crack exist.

If the cylinder walls are scored, one will see the liquid at but few points about the lower edge of the piston, and, as the gasoline washes the oil away, possibly the score marks also will be seen.

In case the trouble is with the rings, the bubbles will be more evenly distributed about the periphery of the piston and will be all of about the same size. Should this latter be the condition, the use of a kerosene injection (about an ounce each night after running the car into a garage) for a few nights will in all probability, eliminate the leak if the rings are only gummed. If this latter is not effective, the job is one of replacing rings.

If the gas is escaping through the rings, then it will be necesary to take out the pistons and look at the rings. If there is a black spot on the rings, it is evident that the gas has been escaping at this point.

Remedying Piston Ring Troubles.

Gummed rings: After long periods of running, a deposit of charred, or partially charred lubricating oil is liable to form behind the ring and interfere with its free movement; it is a good plan, therefore, when overhauling the engine to slip off the rings from the piston and thoroughly clean out the grooves.

A kerosene oil treatment to loosen rings: I have known engines to lack power from merely the rings becoming gummed up. This trouble can be remedied by first running the engine until it is warm, then stop, take out the spark plugs, fill each cylinder full of kerosene by pouring the kerosene through the spark plug holes.

Plug up the holes with old spark plugs and then crank the engine several times by hand so that the oil will work its way down around the rings; leave this oil in over night and next morning crank the engine quite a number of times until you think the oil has passed into the crank case. Drain the crank case. After draining and putting in fresh lubricating oil, start the engine. The engine will smoke considerably to begin with, but this will soon pass away. This will not only loosen up the rings, but will also clean any carbon that may have become deposited in the combustion chamber. This treatment oftentimes saves the trouble of fitting new rings, and in some instances will make a marked difference in the running of the engine. (see page 201).

If the ring is broken or it is dull and dirty in spots and streaks (see page 655), then a new ring or rings must be fitted.

If ring is cut or scratched, a new ring is necessary.

If walls of cylinder are cut or scratched, then rebore, grind or ream, as per page 653, and fit oversize rings as per page 609.

If the ring has lost its tension and does not spring freely against the walls of the cylinder, then it must be treated as shown in fig. 3, page 657.

Remedying Excessive Smoke.

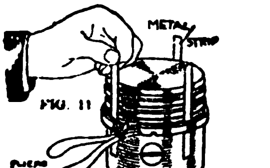
As previously stated, if the rings are leaking, an excess of smoke will pass out the exhaust, caused by oil passing the rings and entering the combustion chamber. see pages 202 and 653.

To test a piston for a leak: Set piston bottom side up in a pan of gasoline and pour about 1" of gasoline into interior of piston—if there is a hole in piston the gasoline will seep through it.

Removal of Rings.

The removal of rings from piston grooves is not difficult if a little forethought is taken: to open them it is best to use a pair of very thin jawed pliers, the jaws opening outward, (see fig. 11) a substitute for pliers can be made from iron wire.

When the ring is slightly expanded by the use of special pliers, similar to those shown in fig. 9, page 659, a narrow slip of very thin metal, (tin or brass will do) should be pushed through the opening and worked to the opposite side of the slot; then if the ring is opened a trifle more, an additional slip of metal can be placed near the ends of the ring, when it can be worked off quite easily and without any risk of breaking it, such as an attempt to expand it larger than the piston diameter would do.



It is a good plan to mark each ring for its own groove, and also when they are not pinned, to mark just where the slots should come on the piston. (see chart 261.)

Peening Piston Rings.

This operation is for a ring which has lost its tension. A peening hammer should be used instead of the various flat-headed types that are used at times for peening a piston ring. The metal may be more readily distributed by the blows from a peening hammer, which can be directed better, since the head is so designed that a large part of the surface is not covered at one time nor struck by any single blow. In this manner slight changes in the shape of the metal may be made without distorting the metal in any way. It is very important in any peening operation that the surface upon which the hammering is done be as flat and hard as possible, for any irregularities in the shape of the surface plate will be just as effective in causing distortions as a blow from a badly shaped hammer. A good method of providing such a surface plate is shown in fig. 3.

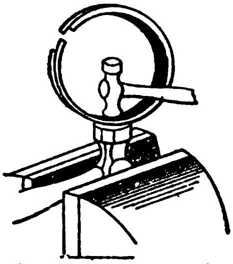


Fig. 3—Peening a piston ring.

*Fitting Ring to Cylinder.

†**After having selected a set of rings, the first operation is to fit them into the cylinder.** Taking one of the rings, try very carefully to shove it straight in, concentric with the cylinder walls; if the ring is of the diagonal slot type (fig. 6, page 655) and its diameter a little large, the ends will run upon each other, throwing the edges out of line; while if a ring with step-cut overlapping ends is used, such as is to be found in some engines, it will not go in at all, therefore ring ends must be filed.

A very simple and effective means of holding a ring for filing is shown in fig. 1. The ring is placed on a block of wood and a few small nails driven into the block both inside and outside of the ring in such a manner that the ring is held securely in place for filing. The heads of the nails are then cut off, the ring removed, and the nails filed down so that they will extend just below the top surface of the ring when it is replaced on the block. With the nails well placed, there will be no danger whatever of breaking the ring when filing. A thin, smooth, flat file is best for this.

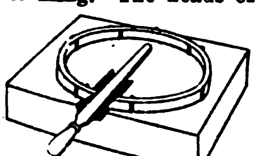

Fig. 1.

The ends must be trimmed off so that when the ring is well up into the cylinder there will be a space about .004", per inch of cylinder di., between ends, per fig. 5, page 649, to allow for expansion caused by heat of the explosions. The groove on the block shown in fig. 1 is used when reducing the diameter of diagonally-slotted rings.

Try each ring in the cylinder, being sure to have it placed about ½ inch from the bottom all the way around, then measure the opening in the ring. Piston rings should have not more than 1-64 in. opening to have a good fit. If it is more than this, compression can easily escape.†

The ring should be repeatedly tried in the cylinder in order that the space is not filed to exceed the dimensions stated. The inside portions of the rings near the ends should rest against the nails in order that they may not be broken off when filing the slot. Having attained the proper space between the ends of the ring, now place a light in the cylinder behind it and see how its face conforms to the wall of the cylinder.

Testing a Ring to Cylinder.

To work or lap a ring to fit cylinder: make a plug of yellow pine (fig. 4) to fit easy into the cylinder and square one end. Lay the ring on this end with a small batten across, secured by a screw through the center, but not holding the ring tightly. Smear the bore as evenly as possible with a little vermilion and lubricating oil mixed to a paste, and move the ring to and fro in the cylinder while held square by the plug. Generally, it will be found to bear hardest at each side of the slot. File such places carefully with a smooth file.

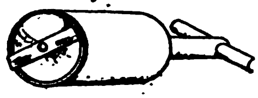

Fig. 4—A handy device for testing and fitting the piston rings in cylinder. This device consists of a round block of wood with handle on one end. The piston ring is placed on the other end and is placed in the cylinder and worked back and forth.

*After fitting rings to piston, they are usually allowed to run themselves in by running engine at moderate speed for the first 500 miles with plenty of oil, during which time the rings will burnish to a nice fit to cylinder wall. Sometimes pistons are lapped in, as explained above (fig. 4) and pages 650, 649. The regular piston should never be used for lapping rings. †See also, page 649, fig. 5, for ring opening clearance.

If one part of the ring fits and another part does not, the high spot shows up when the ring is dipped in gasoline and then rubbed with cloth. The high spot will be more shiny than the rest.

When the ring fits well all around, the overlap of the ends should be absorbed; if not, file them until the edges have about 1-64 clearance when the ring is in the cylinder.

If the ends of the rings be hard butted against one another when in place in the cylinder they may be buckled by expansion when hot, and make starting a two-man job; therefore, file them as shown in fig. 1, page 657 and be sure there is a clearance.

If there is a contact all around, when testing rings in the cylinder, the ring is then ready to be fitted to the piston; but if the contact is poor, either the ring or the cylinder is out of round, leaving space between cylinder wall and the ring, as at C and P in figs. 2 and 2C. If the fault lies in the ring, the face can probably be dressed down to fit, or another selected; but if the cylinder is badly out of round, it will have to be rebored or reground, or both, as the case may be, or (in extreme cases) replaced with a new cylinder.

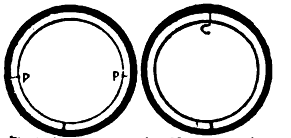

Fig. 2—Cylinder out of round.

Fig. 2C—A sprung piston ring, see C. This shows that the ring was sprung in putting it on the piston.

*Fitting Rings to Piston.

†**When the rings have been fitted to the cylinder, the next operation is to fit them in their respective grooves on the piston.** As regards the fit of the rings in the grooves, they should be just a free fit, neither tight enough to jam, nor slack enough to rock.

Tight rings may be eased by grinding or lapping the edges on a sheet of fine emery or crocus cloth, fastened to a piece of board planed quite flat. The ring is gently rubbed backward and forward with a downward pressure. (see fig. 3.)

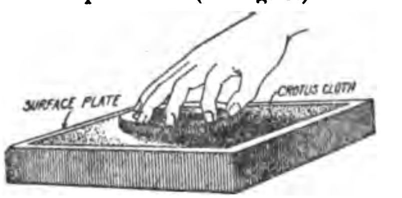

Fig. 3—Method of dressing or lapping piston ring to fit the groove in piston on a surface plate.

***Lapping** should not continue for a long period on one side. The ring should be turned over occasionally. After lapping, the ring should be immersed in clean gasoline and fitted to the groove. Not any groove, but the groove which it nearly fitted before. If every part of the circumference of the ring fits every part of the groove then lapping is complete and the ring may be tagged to designate its location. 1-1 on a tag is made usually to represent first cylinder, ring number 1. Ring 1 is that nearest the top of the piston.

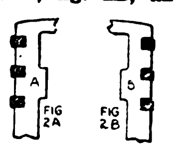
To properly dress down a ring requires some skill, and a good mechanic will select a ring which will demand the least amount of trimming, for it is a delicate operation.

Most manufacturers now cut the grooves in the piston, and grind the face and edges of the rings to a gauge, making very little hand-fitting necessary. But there are cases, (and these are the ones that generally come into the repair shop) where the cut was just a trifle larger, or the ring a little smaller than the gauge, making it essential that each ring be individually fitted to the groove in which it shall subsequently rest.

When fitting rings in the grooves, begin with the ring selected for the bottom groove, so that ring will be the first to be slipped onto the piston. First try the ring without slipping it over the piston by inserting it in the groove and rolling it around its circumference, to see if groove is deep enough and wide enough at all points.†

It should fit snugly, as at A, fig. 2-A, but still be free to slide in and out easily; if it binds in any place, apply a thin film of red or black lead or Prussian blue in the same manner as used in scraping bearings, to locate the high places, then dress down with a smooth, flat file and try again. When filing is necessary, it should be confined to one edge in order that at least one good edge is retained, for it is almost impossible to secure as regular a surface with a file as that made by a grinding machine or on a surface plate.

An example of ill-fitting rings is shown at B, fig. 2B, and in fig. 2C above. The space C shows that the ring was sprung in putting it on the piston.



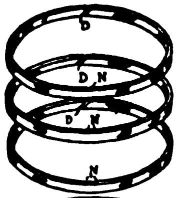
Having fitted one ring, put it in place immediately and repeat the operations with the next ring. See fig. 12, page 659 for slipping rings in grooves.

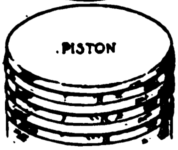
After fitting new rings engine will require considerable running with plenty of good oil to properly work them in, before the engine will give its proper power. See also pages 793, 203, 507, 589, 643, 655.

***When fitting patented rings** remember, if the rings are absolutely tight they might prevent lubrication altogether and cylinder would run dry. Therefore many place merely one patented ring in the top groove and the regular rings in the other grooves.

The patented type of ring requires very little lapping by hand. When put in the cylinder, the engine is allowed to run by belt a few hours, you will find that that is all the lapping that is necessary, unless of course, the cylinder is scored or badly out of round. In such cases, the proper remedy is to have the cylinder rebored, and new oversize pistons made and piston rings made to fit the new diameter of the cylinder.

†See also, page 649.





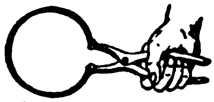


Fig. 9—Piston ring plier

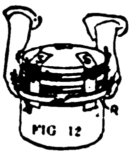

Fig. 8—A serviceable device (O) for compressing rings when fitting piston (P) to cylinder. Especially adapted for Ford pistons which are not champfered.

This tool is bored with a long gradual taper which allows the open rings to enter easily at the top. It is placed in position over the cylinder, and as the piston is forced downward into place, the rings are gradually compres s e d sufficiently to enter the cylinder.

Fig. 10—Method of replacing a piston in the cylinder with a string holding the ring in its groove.

Marking Piston Rings When Removing.

The amateur or junior repairman who removes the piston rings from a piston for the first time; either for examining the pisten-ring slots for sand-holes or wear, or for cleaning the rings and slots, generally neglects to see that the rings are marked so that they may be replaced in their proper grooves. The result is that considerable difficulty often is experienced in getting the rings back into the piston in good order. To avoid this, one foreign manufacturer of motor cars, marks the piston rings as indicated.

The ring in the top groove of a piston has one notch N in the upper, inner edge, opposite the diagonal (D) where the ring is thickest. This notch is made with a file and is very small, so as to be just visible, but at the same time not deep enough to weaken the ring. In a similar manner, the next ring below it is marked with two notches and the third ring, with three notches. If more rings are used a corresponding number of notches are employed to mark them. With rings thus marked there should be no difficulty in getting rings replaced in their proper grooves. Care should be taken, however, when the rings from more than one piston be removed at the same time. In fact, it is advisable, to remove, clean and replace the rings of one piston, before removing the others.

Fitting Rings to Grooves of Pistons.

Fig. 12—A quick and safe method of slipping rings into the grooves is shown in fig. 12. Take three strips of sheet metal, brass or tin (S), for instance, about 1/32 inch thick, ½ inch wide and 5 inches long; bend these at right angles and hang them on the edge of the piston at equal distances apart. The ring (R) may then be slipped over these skids till it is opposite its groove, when the strips may be removed and the ring allowed to slide into place. Install ring in lower groove first and work to top groove last. The same strips may also be successfully used in removing the rings. (See page 649, how to measure ring clearance.)

When fitting rings place the best fitting ring at top, so that oil below it cannot be consumed by the high temperature of the exploding gas. If fire flows past the rings into the crank case, oil will be burnt off of the piston and cylinder wall, causing it to become scored even though your oiling system might be working perfectly with the best grade of oil.

When placing the rings on the piston ready to replace the cylinders they should be set with the joints (if it is a piston with three rings) about one-third way from each other, so that the openings will not come in a straight line or be close together.

Replacing Piston in Cylinder.

Before putting pistons into cylinders, oil (cyl. oil) inside of cylinder and inside of piston as oil will not have a chance to reach upper portion when first starting.

When replacing piston in cylinder, some device must be provided for holding each ring in its groove so it will easily enter the cylinder. **A string may be used** to advantage, as shown in fig. 10. A better method however, is shown in fig. 8.

Replacing cylinders over pistons: It is not difficult to put a single cylinder back on its piston after it has been necessary to take it out, but it is not so easy when the cylinders are cast in pairs, as it is difficult to guide the rings into the cylinder barrels simultaneously. The job is greatly simplified by taking the precaution to place the cranks up and down, so that one piston is at its highest point and the other is at its lowest. This means that the pair of cylinders can be dropped straight over the pistons, the rings of the upper piston being guided into the cylinder before those of the lower pisten are replaced. When it comes to dropping one of the mono-block castings of four cylinders on to four pistons, it is still best to work this way, so that only one other pair of hands are required and that the two upper pistons may be guided into their cylinders first and then the two lower ones.

Note: When reinstalling a piston be careful not to push it up into the cylinder as far as it will go, the upper ring may jump over the valve opening, holding the piston until the ring is released which is a difficult task to remedy.

Aligning Pistons and Connecting Rods.

Incidentally, it would be well to note that many times knocks that develope in engines (after same have apparently been thoroughly overhauled), is often due to the fact that the connecting rods are slightly bent sidewise, out of true in fitting cylinders down over the piston. One cylinder will get a slight lead, or one ring does not properly enter, cylinders are twisted and in an effort to align them, rods are bent. When engine is finally assembled it is very noisy, due entirely to the fact that one or more of the rods have been bent sidewise, and when the force of the explosion is exerted on the piston head, the wrist pin end of the connecting rod is driven side-wise against the piston boss. See foot note bottom of page 649.

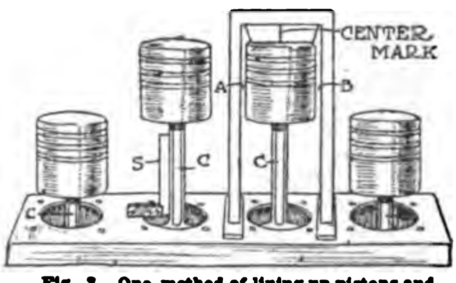

Fig. 3—One method of lining up pistons and connecting rods of block type engines. S-represents a square placed alongside the connecting rod C to determine whether it is true or not. (see also page 649.)

To test its alignment, place the U frame over it as shown, so that center of piston is in line with center mark on cross member. When distances A and B are equal, piston is true and square. See also page 646, figs. 1 and 11 and foot note page 649.

CHART NO. 261—Marking Piston Rings. Lining Up Pistons and Connecting Rods. Appliance for Removal and Replacement of Rings. See page 649; how to measure piston and ring clearance.

Tools for aligning pistons, connecting rods etc., can be secured of John Peyer, 301 W. 88th St., New York, and Stevens Co., 375 Broadway, New York.

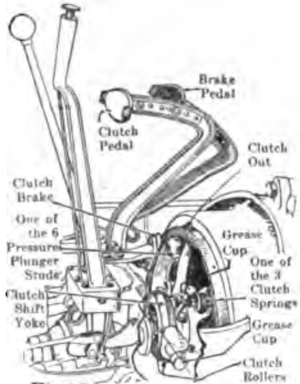

Fig 10 Clutch and its operating mechanism

Cone Clutch Adjustments.

The adjustments are with clutch springs (fig. 10), which tend to keep the clutch engaged. While it is possible to adjust these springs to avoid shifting, the tension should be as little as possible. **Tightening** the springs too much will not only make clutch hard to disengage, but will tend to make the clutch "grab." **Adjustment is made by increasing or decreasing the spring tension of the three clutch operating springs,** by advancing or backing off the nuts on clutch springs. (On some clutches spring is on the clutch shaft per fig. 2, pages 664 and 665.)

The clutch pressure or plunger studs (fig. 10) consist of six small spring mounted clutch plungers placed under clutch leather, which raise it at various points and allow gradual engagement of the friction surfaces. Should these plungers become fast in their guides, or should anything prevent the leather over these plungers from first coming into contact with the seat in the fly-wheel before the entire surface engages, "grabbing" will result. They should be adjusted so that with clutch in complete engagement approximately ⅛" remains between the adjusting nut of the plunger stud and guide to cone.

Clutch rollers (fig. 10), which by pressure upon **clutch shifter yoke** disengage the clutch from fly wheel should be kept well greased—see also fig. 19, page 666.

Ball thrust bearings (fig. 16, page 661), should be supplied with oil by placing oil can spout through spokes of clutch drum.

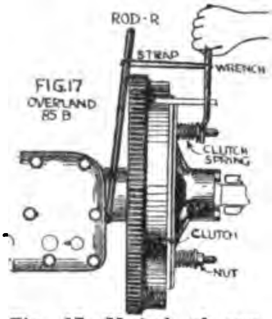

Fig. 17—Method of compressing clutch spring to remove or replace nut—see also fig. 8, page 647.

Clutch brake—is for the purpose of keeping the clutch from spinning when thrown out. See fig. 10, it consists of a small spring mounted fibre pad attached to left of frame, against which the clutch cone strikes when disengaged. It should be so adjusted that when pedal is pressed half way down the cone should just begin to come in contact with it, so that by time pedal is all way down, the spring on clutch brake will be fully compressed.

To remove or replace clutch spider or cone; see fig. 17—the three clutch springs are very powerful. A simple method of compressing the springs so that the nuts can be put on or taken off is explained in illustration—see also figs. 1 and 2, page 664 and page 665.

Before clutch can be removed, it will be necessary to remove the universal joint and parts adjoining the clutch.

Fitting New Leather To Cone Clutch.

First be sure that replacement is necessary. See pages 661 and 662 and note the causes of trouble.

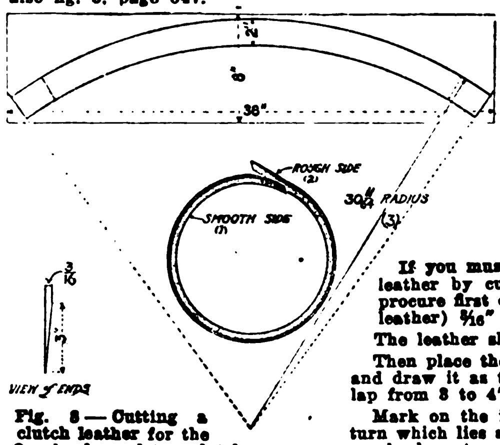

Fig. 8 — Cutting a clutch leather for the Overland roadster clutch.

If leather is worn or rivets project, then it will be necessary to remove clutch to either replace leather or drive rivets down below the surface of the leather.

If a shoulder of about 1/16 or 1/32" has worn on leather, then by carefully trimming it off with a file or rasp will permit cone to go further into fly wheel and may be all that is necessary—together with cleaning the whole surface of leather and removing oil or glaze and then applying Neats foot or castor oil dressing.

If however a new leather is necessary then procure it of the dealer of the car if possible. It comes cemented ready to apply and can be slipped over cone and driven into position with a mallet or piece of wood.

If you must make the leather facing, then first remove the old leather by cutting the rivets with a chisel and hammer. Then procure first class unstretchable leather belting (or chrome tanned leather) 5/16" thick for the new leather.

The leather should be first cut as shown in fig. 8.

Then place the leather over the clutch cone in the correct position and draw it as tight as possible. The leather, if cut as shown, will lap from 3 to 4".

Mark on the inner side of the lapped leather the end of the first turn which lies against the cone. Next remove the leather and measure back or toward the long end of the leather ⅝ of an inch. Measure back from the unmarked end of the clutch leather 3" and bevel the leather off as shown in the illustration. Add 3" to the corrected length of the leather and bevel this end as shown.

The leather may now be cemented and after it is thoroughly dried may be installed. **Always put rough or flesh side on outside.**

For the kind of cement to use, ask a harness maker.

Before a new clutch leather is installed, it should be thoroughly soaked in Neat's foot oil and stretched tightly over the clutch face. Before the leather is fastened to the clutch drum, the "clutch plungers" (or pressure studs) should be forced in below the surface of the clutch cone and held in this position by the clutch plunger adjusting nuts which may be screwed up on the stem of the plunger.

Fig. 12.

Fig. 12—A suggested method of forcing a new clutch facing on a cone by drawing cone into it by a bolt as shown. A small amount of shellac is applied to the clutch and allowed to set before the stud nut is loosened. After this leather pegs are used to complete the bond between leather and clutch. (Motor.)

In riveting the leather on to the cone, extreme care should be exercised to see that the rivets are properly clinched or turned over on the inside of the clutch cone and that the heads are driven into the leather of the clutch face until they are well below the surface. Unless this is carefully done, the clutch will "grab" or engage suddenly with consequent disastrous results. (see also page 664 fitting clutch leather to Chevrolet cone clutch.)

HART NO. 262—Cone Clutch Adjustments. Fitting a Cone Clutch Leather. Overland Roadster as n Example—see fig. 4, page 647 and fig. 19, page 666 for Overland 75B.

An alternative sometimes used for older makes of various cars—is "raybestos" strips as used for brake lining. It is made in parallel lengths and riveted to cone in six or eight sections, the edges being cut at a slight angle according to the diameter of cone.

INSTRUCTION No. 46-A

REPAIRING AND ADJUSTING CLUTCHES, TRANSMISSIONS AND AXLES: Cone and Disk Clutches. Removing Wheels and Shafts from Rear Axles. The Differential.

*Cone Clutch Repairs.

Clutch—How to Use Properly.

The clutch on an automobile should be either in or out absolutely.

Many good drivers make it a plan to keep their foot off the clutch pedal while they are driving. The weight of the foot on the pedal and a little nervous tension in the driver's leg is sometimes just sufficient to hold the clutch out just far enough to "slip it" on a hard or sudden pull.

Another good way to spoil a clutch is to throw it out in traffic until the car comes almost to a standstill—then to speed up the engine and slip the clutch in with the gear shift lever still in high speed.

When the car slows down with the clutch out, the gear lever should be slipped to second speed and if the car comes to a full stop, to low speed.

Another important point in driving is to learn to engage the clutch gradually and not to "bang" it in with the engine racing.

It is always better to run on the engine as much as possible, throttling it down instead of constantly throwing "out" the clutch.

A well adjusted clutch takes hold gradually, does not slip after it has come to a seat, and releases instantly when the pedal is depressed.

Parts of a Cone Clutch.

Cone; leather facing over cone; ***clutch springs** which hold the tension of cone to fly wheel; **pressure or plunger studs** which are spring mounted and placed under clutch leather at various points and allow gradual engagement of frictional surfaces. The "grabbing" feature is eliminated by the use of these plungers, usually six, inserted under the leather as in fig. 4, page 666 and fig. 10, 660; **clutch rollers** on the shifter yoke; **ball thrust bearings** on clutch shaft; **clutch brake** which prevents spinning of clutch—see fig. 10, page 660 and fig. 16, below.

Cone Clutch Troubles

Cone clutch troubles are either fierce engagement or grabbing, slipping or spinning. The latter trouble makes it difficult to shift the gears of the transmission.

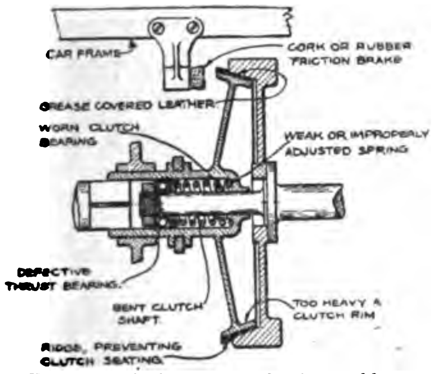

Fig. 16. Various cone clutch troubles illustrated. (from Motor.)

Cause of Clutch Grabbing.

Clutch leather dry or hard. This can be remedied by applying neats foot or castor oil by first cleaning leather with kerosene using an oil gun to remove any mineral oil.

Clutch rivets projecting, due to wear of leather. Remedy by placing a center punch against rivets and hammer until below surface of leather. A grating or grinding sound will indicate this trouble.

Clutch lever linkages out of adjustment. The amount of movement between the surfaces of clutch is small and it is important that no looseness exists in the pedal connections.

Excessive tension on spring clutch—if excessive weaken the spring tension. Excessive tension also causes undue strain on the ball thrust bearings.

Plunger studs improperly adjusted—the six small studs, fig. 10, page 660 should be properly adjusted—see page 660 and fig. 4, page 647.

Clutch rollers may be worn, due to lack of lubrication. If run dry they are liable to seize and prevent clutch release entirely in which case new rollers must be fitted—see page 660 and fig. 19, page 666.

Cause of Clutch Slipping.

Burned or worn clutch lining—usually resulting from allowing clutch to slip when starting, speed changing and using clutch too much, instead of throttle while running. Even though worn to a certain extent Neats foot or castor oil will sometimes improve its operation. Otherwise a new clutch leather must be fitted.

Clutch leather oily and greasy—the cure is to either wash the oil off by spraying a pint or so of kerosene with an oil gun, over the clutch leather, while holding the clutch out, or wiped off with a cloth moistened with kerosene and then dress leather afterwards with Neats foot oil. The oil can also be absorbed by using powdered Fullers earth or talc sprinkled over the surface and leave standing for a while. Don't use dirt or sand—it will cut the leather.

***The clutch spring** can be arranged as shown in fig. 10, page 660, or as fig. 16 above. and fig. 2, page 665.
See also pages 38, 647, 666 for cone clutch explanations and adjustments.
See also pages 543 to 545 for type of clutches used on different cars.

Leather worn down—if it cannot be raised enough by adjustment of the plungers, fig. 10, page 660, then a new leather must be fitted.

When the surface of the clutch and seat are new, they touch all over, but when worn, they touch on only the high places. If the surfaces touch in only a few places, they naturally cannot transmit the power that is possible with a good contact; they can be forced to transmit it by pressing them more firmly together, but it is better to reface the surfaces.

Clutch spring tension weak—tighten adjustment, see page 660. If no adjustment nut on spring, place a washer between spring and its seat. **Also examine the pressure or plunger studs**, fig. 10, page 660.

Clutch shift out of line—sometimes caused by two great a spring tension causing balls to break in thrust bearing and cutting ball race, lowering the clutch shaft out of line. Also may be due to a bent clutch shaft or clutch shaft out of alignment—see fig. 3, page 732.

Ridge worn on the rear of clutch leather—see page 660 for remedy.

*Clutch Spinning.

When a clutch spins, when thrown out of engagement, it is difficult to shift gears.

Clutch spinning is often due to excessive friction in the spring thrust bearing (see fig. 16), though sometimes faulty alignment of the flywheel and clutch cone prevent the engaging surfaces from entirely clearing each other. A bent clutch shaft might be the cause of this.

Sometimes the fault lies in the clutch, a heavy rim or cone will store up energy and continue to revolve when disengaed.

When a clutch spins from lack of alignment or adjustment the remedy is obvious, but if the fault is in the design, a clutch brake (see fig. 16 and page 660, fig. 10), should either be fitted, or the clutch rim lightened by drilling or machining away metal at or near the outer circumference.

Cone Clutch Lubrication.

Lubrication of a cone clutch is usually at the rollers or clutch yoke and **ball thrust bearings**—otherwise oil should be kept from the clutch leather as much as possible as a leather faced cone is supposed to run dry, but yet kept flexible, which it can be by use of Neat's foot or castor oil as explained.

If Clutch Fails to Release.

Usually termed as a "frozen clutch." This may be due to rusty or tight pedal connections or loose pedal linkage connections; clutch yoke rollers run dry and sometimes, from too tight a spring adjustment.

The amount of movement between the surfaces of a clutch is small and it is important that no looseness in the pedal connections or bending of the levers should exist to prevent gradual engagement.

A Clutch Brake.

If it is desired to atach a clutch brake or dampener as explained on page 660, to check the revolving of the cone, either cork or rubber can be fitted into a metal bracket and this bracket attached to the car frame.

The position of the brake should be just to the rear of the clutch rim, against which the clutch will draw when the disengaging pedal withdraws the cone.

Miscellaneous Clutch Pointers.

Fig. 1: A clutch or jack can be placed as shown to hold clutch out while working on it.

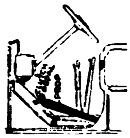

Fig. 1.

Fig. 2: The cone can then be turned by hand and Neats *foot* oil applied, or oil gun of kerosene for cleaning.

Fig. 3: An insect powder gun, filled with talc or powdered Fullers earth for temporary remedy of an oily slipping clutch or brake.

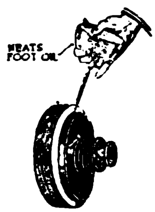

Fig. 2.

Fig. 3.

Another Example of Adjusting a Cone Clutch—The Mitchell.

Clutch adjustment. The only adjustment of clutch is the three coil springs "C" (fig. 17) which tend to keep the clutch engaged. While it is possible to increase the tension of these springs to avoid slipping of clutch, the tension should be as little as possible. Drawing the springs up too tight will not only make it harder to disengage, but will tend to make clutch grab.

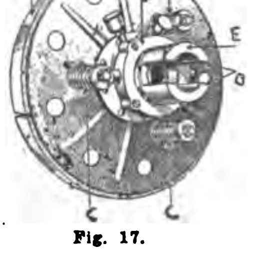

Fig. 17.

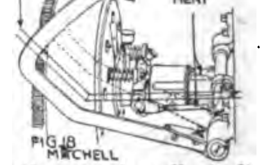


Clutch pedal adjustment: The left foot pedal, which actuates the clutch, can be adjusted for different positions by adjusting the two rods connecting the clutch pull shaft with the clutch yoke, but care should be taken to see that both rods are adjusted the same (see fig. 18.) Care should also be taken that the rods are adjusted so that when pedal is depressed clutch will fully disengage and that pedal does not strike toe-board when clutch is engaged.

*The shift of gears by gear shifting lever ought to be made without a particle of noise if clutch is thrown out when shifting. If there is noise, then it is usually due to clutch not being fully thrown out or dragging or spinning or transmission shaft, or transmission shaft out of line due to worn bearings.

*The Disk Clutch-Adjustments and Repairs.

There are a number of cars in use having disk clutches on which the adjustment is made by means of a series of three or more separate studs or screws. Much trouble often is experienced by motorists who try to adjust this type without a knowledge of how it should be done.

Adjustment Method.

The proper way to adjust this type of clutch is to unscrew or release them entirely from contact with the plate or mechanism inside the clutch casing, then screw them up carefully with the fingers until each one just begins to touch, which is indicated by an increase in the effort required. When each screw or stud has been turned up so that it just begins to touch the plate or mechanism against which it bears on the inside of the clutch casing, then with the aid of a wrench, give each screw a half-turn forward and repeat, until the proper adjustment is obtained. The object is to give each screw the same number of turns and at the same time have them all move forward at practically the same time. If one was to give one screw five or six full turns and proceed to the next one and give it the same number of turns, etc., until all had been turned up the same amount, the same results might be obtained; but it is most probable that the job would not be successful, and perhaps damage to the internal mechanism of the clutch would ensue as a result of possible binding or cracking. On the other hand, if the studs were screwed alternately, little by little, but no care given to the relative number of turns given to each, the springs or operating mechanism would most likely bear unevenly upon the disks, and a jerky, grabbing or slipping action of the clutch would result.

**Slipping of Lubricated Disk Clutch.

When an inclosed disk clutch which runs in oil has been giving good service for a reasonable length of time and then develops a tendency to slip, or perhaps to take hold too fiercely, the trouble should not be taken immediately for an indication that the clutch is in need of adjustment. Before altering the adjustment of a clutch of this type, one should first drain out the old oil, inject a pint or more of kerosene, preferably with a squirt gun, then close the opening to the casing, start the engine, and with the gear-shifting lever in the neutral position, operate the clutch pedal so the kerosene may be thoroughly distributed and the internal mechanism of the clutch well rinsed and cleared of old and sticky oil. Then drain the clutch casing, flush it out once or twice with fresh, clean kerosene, and refill to the required amount with clean oil.

If after this treatment the clutch still slips, draw out a little of the oil and replace the amount taken out with kerosene; by thinning the oil this way better contact between the plates is obtained and slipping is reduced. Unless the proper proportions of oil and kerosene are known, the lubricant may have to be thinned down gradually until the proper mixture is obtained; but once found, the extra trouble is rewarded by a fine, smooth action.

Should it be found slipping cannot be eliminated by means of thinning the lubricant, then an increased spring tension may be required, which can be obtained by tightening or screwing up all adjusting studs evenly all around. It is good motor practice never to disturb an adjustment unless having an absolute knowledge of the operation and effect of the adjustment.

**Clutch Grabs or is Fierce.

When a clutch of the disk type running in oil takes hold too fiercely, drain out the oil, rinse with kerosene as previously described, and refill to the required amount with clean, fresh oil; if this does not prove a remedy, readjust the clutch by loosening all studs entirely and then tightening them until best action is obtained.

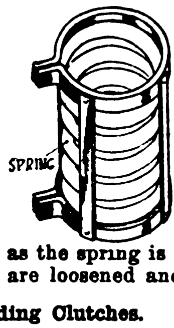
When clutch is new, there may be a slight tendency to slip, owing to the stiffness of the fabric with which the driving disks are lined. No adjustment of the spring is necessary to regulate this condition, as it will entirely disappear after the car has been in use a short time, therefore don't be too hasty in making adjustments.

*The Single Plate Clutch.

Is the type of clutch which is most gen-generally used. This type runs **dry** and is the simplest of all clutches. see page 42 and page 668.

†Replacing Clutch Springs.

In replacing a series of springs, such as clutch springs, it is usually advisable to compress the spring in a vise and then hold it in this position until it is put in place on the car. Under certain circumstances the device shown will be found very convenient. It holds the spring by friction, and consists merely of two clamping rings. As soon as the spring is in place the retaining screws are loosened and the tool is removed.



Internal Expanding Clutches.

Internal expanding clutches, in which metal acts on metal, sometimes give trouble from the melting of the metal due to the heat of excessive slipping. This will lock the two parts of the clutch together so that pressing on the pedal will not release them.

To separate them, the engine must be stopped and the high speed gear engaged. The car should then be pushed forward and backward by hand, which will jerk the clutch and release it.

The same trouble occasionally comes with friction cone clutches that are too fierce, and they may be separated in the same manner.

*See pages 543 and 545 for types of clutches used on different cars; page 666 Hudson; 40 for Cadillac clutch and pages 42, 668 for single plate clutch. See page 667 for Reo clutch, pages 666, 932, Dodge.

****Usual cause of slipping of lubricated disk type** clutch is due to improper clutch spring or clutch pedal linkage adjustment which prevents clutch plates from engaging. If this type clutch **drags**, it is likely due to **oil being too thick**. If it **grabs**; likely due to lack of oil or improper clutch spring adjustment. **See pages 668, 842 for adjustments and troubles of a dry disk type clutch. See** pages 666 and 931 for Dodge clutch.

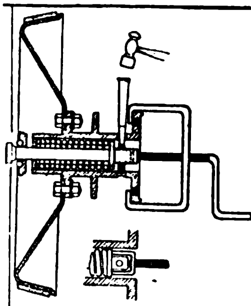


Fig. 1—Showing the method of compressing the clutch spring, permitting the lock pin to be removed

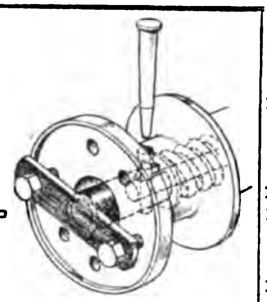

Fig. 1A—Another form of clutch spring compressor, somewhat simpler than that shown in Fig. 1

Fig. 2—The thrust bearing assembly is held together by three old valve springs, placed in the manner shown

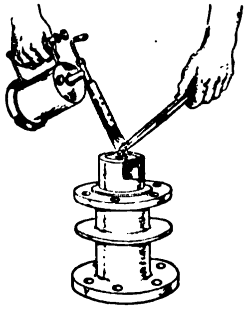

Fig. 4—When loose, the plug in the end of the clutch hub should be sweated back in place

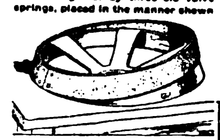

Fig. 3—The new leather should be fastened at the ends, and then forced over the face of the clutch'

Chevrolet "490" clutch repair as an example.

Evidence of Trouble.

1–A heavy grinding noise when the clutch is released. This is usually caused by worn or broken balls in the clutch thrust bearing.

2–Actual failure of the pedal to release or move the clutch or to come back into position when pushed out: This indicates that the clutch spring retaining plug has become unsoldered and has unscrewed from the clutch hub.

3–Excessive slipping of the clutch, that cannot be cured either by application of Neat's foot oil, if dry, or Fuller's earth, if slippery.

The first necessitates a complete removal of the clutch, together with the flywheel and anchor stud; the second a removal of the clutch hub, and the third the removal of the hub and clutch.

Procedure.

1–Remove floorboards.

2–Remove wiring running from battery to starter.

3–Remove the three bolts holding V-brace to engine base and gearbox support and remove the V-brace.

4–Disconnect brake rods from pedals.

5–Remove bolts holding clutch release shaft to gearbox support and remove clutch release cross shaft, together with pedals.

6–Remove bolts on rear clutch hub drive ring.

7–Remove the four bolts holding gearbox to gearbox side arms. (Care should be taken in removing the shims under the gearbox, so they may be replaced in the same position.)

8–Remove one bolt holding the left gearbox side arm (on the pedal side) to engine. (This permits the gearbox side arm to spring to one side in removing the gearbox.)

9–Lift gearbox up and slide it forward. It may then be removed from the chassis. (A jack should be placed beneath the propeller shaft to hold it in place when the gearbox has been removed. In some cars it is necessary to spring the gearbox arms apart or to force the gearbox out with a jack.)

10–Turn the flywheel until the hole passing through the clutch hub is at the top, and the clutch spring retaining pin is in line with the hole.

11–Using either the compressor shown in fig. 1 or 1A; compress the clutch spring. The clutch spring retaining pin will usually drop out when over the hole in the housing; but, if not, may be driven out with a drift and hammer.

12–Draw clutch spring out.

13–Remove bolts holding clutch hub to clutch spider, and remove clutch hub. (This is necessary, as the hub would otherwise interfere when removing the clutch.)

14–Pull clutch out. (This will take some little effort, as the gearbox arms squeeze onto the clutch and must be sprung. But it can be pulled out.)

15–Remove nuts holding flywheel to crankshaft flange and with a bar loosen flywheel and remove. (It is advisable to mark the position of flywheel on the flange so it may be replaced in the same relative position.)

16–Remove flywheel together with clutch spring anchor stud and place in on two boards nailed to the bench.

17–Separate all parts and clean with gasoline and waste.

Clutch Troubles.

Clutches of this type give but little trouble if properly used and the necessity for relining is only occasional. If slipping has been experienced and the leather is damp, it is usually because it has been soaked with mineral oil. This may be removed by cleaning the leather with gasoline, after which Neat's foot oil should be applied to keep the leather flexible.

Grabbing. Though a dry clutch will occasionally cause slipping it more usually causes "grabbing." Unless the leather is burned, or worn out, it may be restored by roughing the surface slightly with emery paper, and then dressing it with Neat's foot oil.

Another cause of a sticking clutch is protruding rivets, and these should again be set beneath the surface of the leather. A small shoulder will also cause trouble, and this should be scraped or filed down.

A new leather should never be fitted unless it is absolutely certain that the old leather cannot be reclaimed.

If relining the clutch is imperative, it is best to obtain the new lining from the makers. If this is not expedient, the old lining should be carefully removed and used as a pattern for cutting the new lining. The new leather should be much thicker than the old lining and of uniform thickness.

The most essential point in fitting the new leather is to have it fit tight and true to the cone.

If the clutch has been relined it will not work perfectly until it has been worked in. This usually takes some time and during that period should receive frequent applications of Neat's foot oil.

To Fit a New Leather.

1–Soak the leather in water.

2–Secure one end of the leather to the cone by one copper rivet (rough side out.) (Never use anything but copper rivets; other metals will score the metal clutch facing.)

3–With only about three-quarters of the leather on the cone, pin the other end to the cone by a rivet. (see fig. 3.)

4–Force the leather up into the cone. It should fit evenly and with uniform tension.

5–Drill and countersink the rivet holes.

6–Rivet the leather in place. Be certain that the rivet heads are 3-32 in. below the leather and well headed on the inner side.

7–Allow the leather to dry slowly. It will otherwise shrink too much and expose rivets. A coarse file may be used to remove the high spots.

—Continued next page.

HART NO. 268—A Cone Clutch Repair—Chevrolet "490" as an Example—see charts 229 to 232 for types of clutches used on different cars.(see pages 671 and 672 for Chevrolet transmission and rear axle adjustment.)

ze of piston ring on "Chevrolet 490" engine is 3 11/16" x 3/16". See page 607 for other piston ring sizes.

—Continued.

Clutch Hub Repair.

If the solder holding the clutch spring retaining plug has become loosened, permitting the plug to unscrew—

1—Clean and scrape both plug and hub end thoroughly.

2—Screw plug into hub until the upper surface is slightly below the hub.

3—Heat end with torch, as shown in fig. 4, and run solder into the joint.

Thrust Bearing Repair.

1—Examine the balls and races of this bearing, and if pitted or showing the slightest indication of wear, the entire assembly must be replaced.

2—Place flywheel on bench, as shown in fig. 2.

3—Force ball race into flywheel casting. This must go in evenly and come to a seat evenly, otherwise the bearing will quickly destroy itself.

4—Assemble the balls and clutch spring anchor stud, packing the balls in grease.

5—Slip the clamp shown in fig. 2 (page 664), over the end of the stud. This holds it firmly in place and permits one man to put on the retaining springs.

6—Slip on three old valve springs over the end of the stud and pin in place, as shown. The clamp may now be removed and the stud, with the thrust bearing, cannot fall apart in reassembling the clutch.
An alternative method, and one commonly used in assembling the anchor stud and bearings, is to place the ball race, balls and anchor stud together before placing them in the flywheel. They may be held together by the three valve springs.

7—Lift flywheel back into place on the engine. Bolt it back in the same position as removed. Do not tighten any one bolt until all are drawn snug. This removes the possibility of having the flywheel out of true, which would ruin the thrust bearings.

8—Remove the pin and three old valve springs from the clutch spring anchor stud.

9—Force the clutch back into position.

10—Bolt clutch hub to clutch spider. Draw all bolts up snug, before any one is tightened.

11—Put clutch spring back in place and pack with grease.

12—Using the compressor shown in fig. 1 or fig. 1A, replace the clutch spring retaining pin.

13—Lift gearbox back into frame. It will have to be sprung past the gearbox side arm.

14—Replace bolt holding gearbox side arm to engine.

15—Replace the bolts on rear clutch hub drive ring. Bring all up snug together.

16—Replace bolts holding gearbox to side arms. (Make certain that the shims are replaced exactly in the same position from which they were removed.)

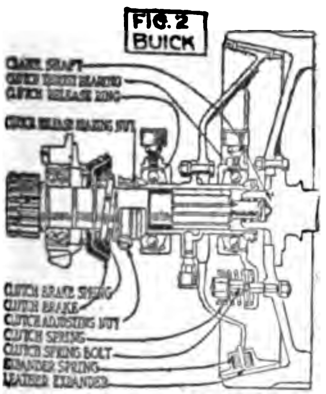
17—Replace clutch release shaft with clutch yoke and pedals.

18—Connect brake rods.

19—Replace V-brake, connecting gearbox support with engine.

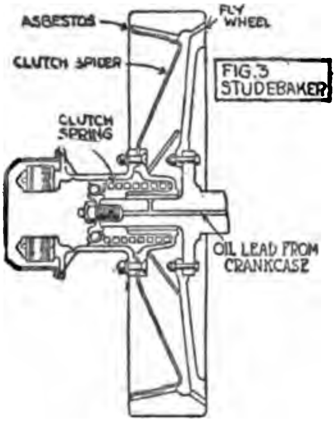
20—Refill oil reservoir on clutch yoke and grease cups on clutch cross shaft. Oil all working parts.

21—Replace wiring. Start engine and note whether everything seems to be working properly. If there is a rattle in the clutch drive ring it will indicate that the gearbox is out of line. The shims will have to be shifted or possibly removed. When perfect alignment is reached the rattle will cease.



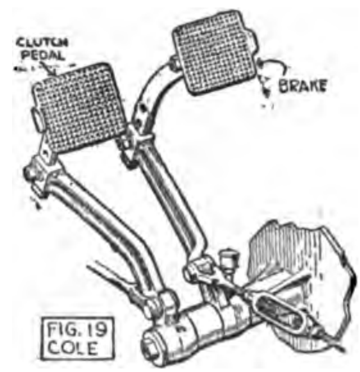
Buick clutch showing adjusting feature and parts which need oiling

Fig. 2.



The simple Studebaker clutch. Tension is maintained by one main spring

Fig. 3.



Foot pedals may be adjusted (for height) by removing the bolt and placing portion of pedal (inserted in fork) where desired.

*Buick 4 Cylinder Car Clutch.

Fig. 2—Buick clutch is a cone clutch. Here again, the regular antidotes for slipping clutch caused by a worn, oily or burned leather, apply.

A worn leather may be made to hold by increasing the tension on the four large clutch springs within the clutch spider. In doing this be careful to turn the nuts exactly the same amount.

When the lining of the clutch brake becomes worn, thus allowing the clutch to spin after disengagement and make the shifting of gears difficult, adjust by loosening the clamp bolt and turning the adjusting nut to the left or counterclockwise. This will compress the brake spring sooner and consequently stop the clutch more quickly.

To grease the clutch, loosen the wing nuts and remove the cover of the clutch housing. Give the grease cup on the clutch release ring a turn or two. Press the clutch pedal and turn the clutch cone around until that grease cup appears and give it a turn or two. Turn the engine over until the grease cup on the clutch spider appears and turn that down the same amount. Apply a few drops of flowing oil to the clutch release yoke trunnion bearings. This operation should be performed every 500 miles.

Studebaker Clutch.

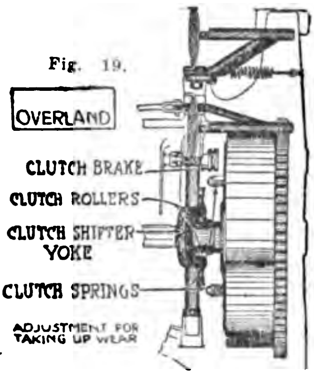
Fig. 3—Studebaker clutch is of the leather-face cone type to which general rules for the care of the leather, renewals, etc., given elsewhere in this book, apply. The clutch bushing is lubricated by an oil lead, bored through the center of the crankshaft which takes lubricant from the oil reservoir of the engine. If, after long service, new linings on the clutch fail to make the device hold properly, the remedy is to wash with gasoline and treat with neat's foot oil.

To remove the main clutch spring; this can onl y be done by completely disassembling the unit, and either increasing the tension of this spring by st retching it out, or replacing it. On rare occasions these springs will break, and of course the only re medy is to replace the spring.

CHART NO. 264—Cone Clutch Repair—Continued. Buick, Studebaker Cone Type Clutch Adjustment. Foot Pedals. *See index for Buick "six" clutch, which is a multiple disk type.

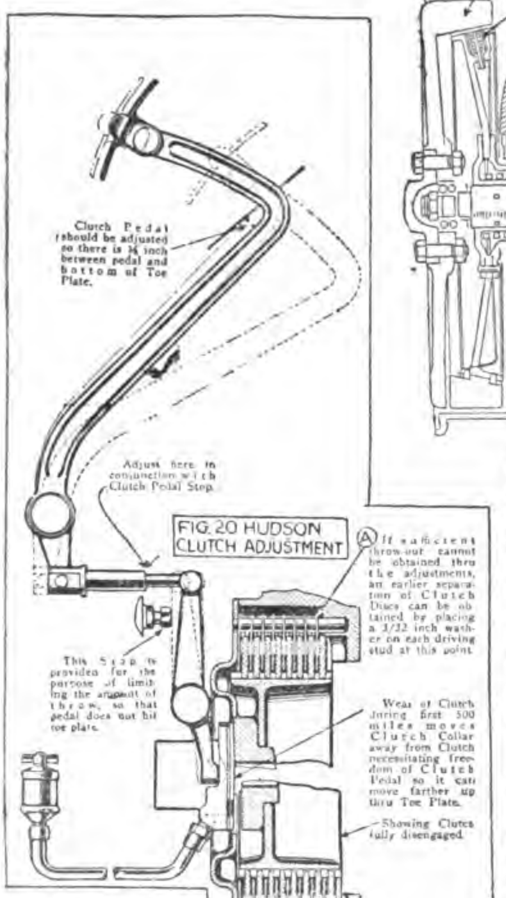
Overland Clutch.

Fig. 19. Cone type, leather faced. Clutch tension is by 3 powerful springs, per fig. 3, page 647 and fig. 17, page 660. To remove springs use pry, per page 647. To increase spring tension, turn nuts in. Each nut to be turned same amount.



Care: turn grease cups down once a week and keep supplied with oil. Oil ball-thrust bearings every 500 miles, which can be easily reached by oil can to side of clutch spokes.

See also, pages 660, 647.



Do not slip the clutch except when absolutely necessary and then only when you know it **has sufficient lubrication to stand it. If you feel that you must do so, owing to lack of confidence in your ability to handle the car through congested traffic, remember that the lubrication of the throwout collar will need more frequent attention.**

*Dodge Cone Clutch and Transmission.

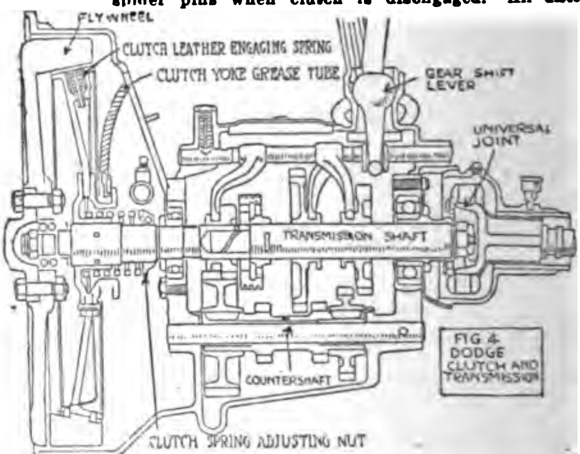
Fig. 4. To adjust clutch: Remove cover plate, loosen clamp screw on clutch-adjusting nut and turn up clutch spring adjusting nut (just below clutch "throw-out" fork) with a screw driver until sufficient compression. Then tighten screw.

Care: keep clutch yoke grease tube filled and be sure it does not clog. Keep drain hole in bottom of clutch housing free so oil cannot accumulate on clutch leather. Turn grease cup down often, on "clutch-throw-out."

Transmission lubrication: Use 1 part medium grease and 2 parts 600W steam cylinder oil and up to ½" of main shaft—see page 670.

*Dodge Dry Disc Clutch.

There are 7 discs held together by a heavy spring (6, fig. A, page 931). The 4 driving discs (9) (covered with wire woven asbestos), are supported on 6 pins (3), pressed and riveted into fly wheel. The 3 driven discs (8) (plain), are carried on 3 pins (7) riveted to clutch spider (4) which is keyed on clutch shaft (32). Fly wheel pins (3) are located outside, or above the clutch spider pins (7), so that they can turn independent of the clutch spider pins when clutch is disengaged. All discs



are free to slide upon their supporting pins and are held together by the clutch spring (6) when clutch is "in."

To tighten clutch spring: compress enough to allow split washer (see fig. 1, page 932), which fits into one of three grooves cut on clutch shaft, to be moved forward to the next groove. The two halves of this washer must fit securely into groove so that clutch spring rear retainer fits snugly around it.

Care: Keep foot off clutch pedal except when used, otherwise disc facings and ball-bearing throw-out will wear excessively. Do not slip clutch unnecessarily, as this causes fabric to become glazed and slip. Keep drain in bottom of clutch housing open.

Lubricate ball bearing clutch release (12) by keeping grease cup, located on the toe board to the right of the accelerator pedal, well filled and give it one complete turn every 100 miles. Make sure that the clutch release grease tube (34, fig. A, page 931), is tightly connected and unobstructed.

Hudson Clutch.

Fig. 20—Hudson clutch is the lubricated disk, cork insert type.

Renewing the oil and lubricating the clutch throw-out collar are the only attentions necessary.

The fact that the cork inserts become saturated with oil makes it comparatively difficult to abuse this clutch as compared with other types. However, its action will be affected if instructions in regard to the quality and quantity of lubricant are not **strictly adhered to. Never put more than a half pint or mixture in at one time. Always drain the clutch to remove the used oil before filling in any fresh oil. Half kerosene and half good engine oil.**

Clutch adjustment (see fig. 20), should be inspected occasionally.

CHART NO. 265—Examples of Cone Clutch and Disc Clutch Adjustments.

***The first 50,000 Dodge cars used the "cone" clutch as above. Later cars use disc clutch, dry type—consisting of 4 driving and 3 driven members. See page 931, 670 and Insert No. 1. See page 689, Dodge Brake Adj.**

Reo Dry Disk Clutch.

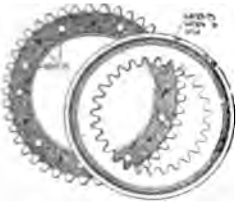


Fig. 1—If worn, the facing should be renewed, and the rivets countersunk below the surface to prevent grooving the steel disks. The steel disks should be renewed if grooved or warped.

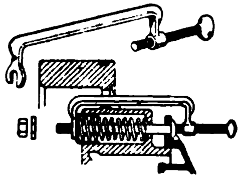

Fig. 2—The assembly is facilitated by the use of a simple compressor, applied in the manner illustrated. It is cast iron, though a similar one could be forged from bar stock. The main thing is to use a compressor of some sort.

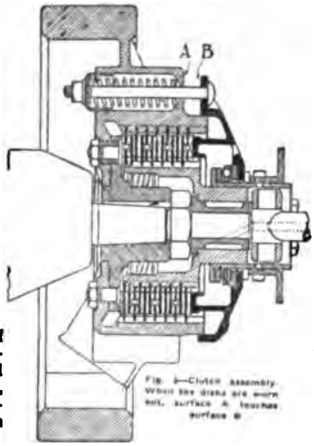

Fig. 3—Clutch assembly. When the disks are worn out, surface A touches surface B.

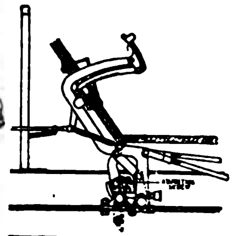

Fig. 4—To adjust clutch opening fingers, turn the adjusting screw on the clutch pedal until the clearance between the fingers and the release plate is about 1/16 in. when the clutch is in. The release plate should then spin freely.

Evidence of Trouble.

1–Slipping clutch: This is often caused by lack of proper clearance between the clutch opening fingers and the release plate. This clearance should never be less than 1/16 or more than ⅛ inch, when the clutch is in. This necessitates an adjustment of the clutch opening fingers. (see clutch adjustment below.)

Another cause of slipping clutch is too little tension on the clutch springs, contained in recesses in the flywheel, as shown in fig. 2. The nuts on the engine end should be tightened enough to prevent the clutch from slipping, but not enough to make the pedal difficult to operate. Never tighten the clutch spring nuts until the release fingers have been adjusted to the proper clearance. Neither of the above adjustments will have any effect if the lining on the disks are worn so thin that the clutch casing seats on the flywheel, as shown in fig. 3, at A and B. When worn thus, the clutch must be removed.

Continual slipping cause the disks to get very hot, warping the steel disks, as shown in fig. 1, and raising the rivets on the lined disks so that they cause the clutch to chatter, with the possibility of grooving the disk and giving them a permanent warp.

2–Noisy clutch—particularly when released: This is due to worn clutch thrust bearing. (see fig 3.) A removal of the clutch and replacement of the bearing is necessary.

To Remove the Clutch.

1–Remove floor boards.
2–Remove starter driving chain.
3–Remove the two battery wires running to starting motor.
4–After removing the two bolts holding the right end of the starter, and the single bolt at the left end, remove starting motor.
5–Remove short drive shaft, with its universals, that connect clutch and gearbox.
6–Remove brake rods.
7–Remove bolts on clutch cross shaft and spring it up.
8–Remove clutch cross shaft.
9–Remove the nuts that hold the clutch spring bolts at the rear of the flywheel. Remove bolts.
10–Pull clutch out and remove from frame.
11–Place clutch ring assembly on bench with clutch rings up.
12–Remove snap ring and then remove all friction rings.
(Note how the rings are removed that they may again be built up in the proper sequence.)
13–Clean all parts with gasoline and scrape out the clutch ring recesses both on the flywheel and the clutch hub.

The Repair.

If asbestos faces of the disks are worn they must be replaced. The split rivets holding them should be opened down below the surface, if the facing does not have to be renewed.

1–To replace facing: Cut off heads of old rivets, taking care that the disks are not sprung out of shape.
2–Examine each disk to see that it is not sprung or warped out of shape, and note whether the steel disks are grooved. If either is the case the disks must be replaced.
3–Using each disk as a template, drill the rivet holes in its new facings. Countersink the facings slightly for the rivet heads.
(The new facings can best be obtained from the car makers, and this should be done if possible.)
4–Using solid copper rivets, rivet the new facing to the disk.
5–Examine ball and roller bearings of the clutch for wear and the clutch bushing for looseness. Replace with new ones, if any amount of wear is evident.
6–Use little grease in assembling the bearings, as the clutch must be run dry.

1–When assembling clutch: Make certain that the rings are inserted in proper relation to each other. (An asbestos faced disk goes in first.)
2–Slide clutch back into place.
3–Using clutch spring compressor, as shown in fig. 2, replace nuts on clutch spring bolts. Do not tighten these nuts yet.
4–Replace clutch cross shaft.
5–Reconnect brake rods.
6–Replace drive shaft and universals.
7–Replace starting motor, wires and driving chain.

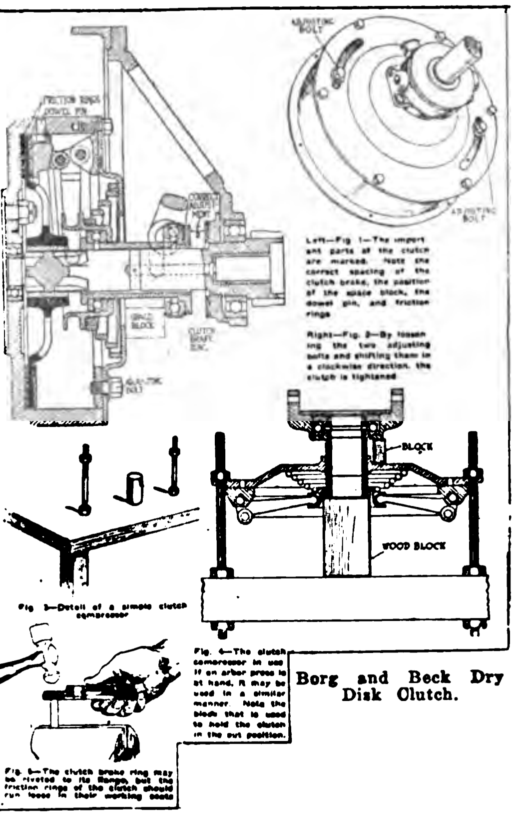
To Adjust Clutch.

1–Adjust opening fingers on clutch throwout collar so that they strike the collar together. This is done by loosening the clamp bolts, holding them to the cross shaft and tapping them into alignment. If this is not done the gears will not shift readily.
2–Adjust the clearance of the opening fingers. This is done by loosening the lock nut on the set screw, as shown in fig. 4, and turning the screw in to decrease the clearance and out to increase. This screw should be turned out until the clutch release collar spins easily on the drive shaft when the clutch is in.
3–Tighten the nuts on the clutch springs at the rear of the flywheel, evenly, and until the clutch does not slip. These nuts should not be tightened so that the clutch pedal works with difficulty.

Maintenance.

1–If the clutch starts to slip, adjust it at once.
2–Use no oil on the interior of the clutch, except as placed in the two oil openings in the drive shaft.
3–Do not drive with the foot on the clutch pedal.

CHART NO. 266—Dry Disk Clutch Repair and Adjustment—Reo Fifth as an Example.
(Motor World.)



Left—Fig 1—The important parts of the clutch are marked. Note the correct spacing of the clutch brake, the position of the space block, the dowel pin, and friction rings.

Right—Fig. 2—By loosening the two adjusting bolts and shifting them in a clockwise direction, the clutch is tightened.

Fig. 3—Detail of a simple clutch compressor.

Fig. 4—The clutch compressor in use. If an arbor press is at hand, it may be used in a similar manner. Note the block that is used to hold the clutch in the out position.

Fig. 5—The clutch brake ring may be riveted to its flange, but the friction rings of the clutch should run loose in their working seats.

Borg and Beck Dry Disk Clutch.

Evidence of Trouble.

1–**Grinding or clashing of the gears,** especially the first speed gears when shifting.
This indicates that the facing of the clutch brake (see fig. 1) is worn and must be either adjusted or relined.

2–**Continual slipping of the clutch** that cannot be stopped by draining and cleaning with gasoline or by adjustment.
This may be due to either excess oil in the clutch casing or to worn friction rings; the excess oil may leak in through the dam which separates the front oil reservoir from the flywheel case. The transmission must be removed and the clutch taken down.

3–**Slipping of the clutch, followed by chattering and grabbing.** This indicates that the asbestos friction rings are glazed and should be replaced, requiring that the clutch be removed.

4–**Actual failure of the clutch to operate, or excessive noise when the clutch pedal is pushed out,** indicating that the clutch spring or some of the operating members are worn or broken, and hence necessitating a removal of the clutch.
(Ordinarily a washing and adjustment of the clutch will place all parts in good condition. Unless it is positively indicated that a removal is necessary, cleaning and adjustment should always take place before tearing the clutch down.)

To Clean the Clutch.

1–Remove drain plug at bottom of clutch housing.

2–Remove clutch inspection plate.

3–Loosen clutch flange retaining bolts holding flange to flywheel. Do not loosen these bolts more than ¼ in.; just enough to allow the oil to drain out.

4–Squirt a little gasoline into the clutch, washing out the residual oil.

5–Tighten clutch flange bolts.
The clutch may slip for a short time until all the oil has been squeezed out. But if it continues to slip or grow worse there must be a leakage from the crankcase that must be stopped, and hence the clutch must be taken down.

If clutch grabs: Take out one of the adjusting screws (see A, page 842) and apply a mixture of 2/3 lubricating oil, 1/3 kerosene, through this hole with an oil gun. As a rule, a bath of kerosene is all that is necessary. Sometimes, merely tightening clutch spring will remedy the trouble. If neither of above, then see 3, under "evidence of trouble."

To tighten clutch—see pages 43 and 842.

To Repair Clutch Brake.

This brake is designed to stop the spinning of the clutch and to prevent gears clashing when shifting. To examine:

1–Press clutch pedal way down.

2–Examine brake and see whether it actually touches the collar or not. If it does not touch, the transmission must be removed. Note how far it comes from touching.

3–Remove gearbox. This method may vary somewhat in the different cases.

4–Examine clutch brake friction band. If in good condition, it will not be necessary to install a new one, as a metal washer placed between it and the shoulder on the main drive pinion will raise it sufficiently to touch the brake. The thickness of this washer depends on the distance the clutch brake and flange were apart, as shown in fig. 2.

5–Unscrew clutch brake (this is a left hand thread) and place the metal washer between it and the drive pinion. It is better to reline the clutch brake after washers amounting to ⅛ in. have been installed.

6–If the clutch brake facing is worn very thin or glazed it should be removed and a new one riveted on in its place. Copper rivets should be used, and they should be countersunk well beneath the surface of the facing. (see fig. 5.)
Providing the adjustment of the clutch is O. K. and the friction rings are in good working order the gear box may now be assembled.

To Remove Clutch

Necessitated by worn clutch rings, actual failure of the clutch to operate or continued presence of oil after repeated cleanings.

1–Mark clutch cover and flywheel so that the cover may be replaced exactly as removed. If the cover should be replaced wrong, the clutch will not operate.

2–Throw clutch out and lock by placing a block of wood (space block) as shown in fig. 1.

3–Remove clutch cover bolts.

4–Draw clutch out.
If all working members are in good condition and not worn excessively new friction rings should be slipped in place and the clutch assembled. It may however, be necessary to completely dismantle the clutch in order to replace the spring or some worn member.

To Dismantle Clutch.

1–Place clutch on compressor, shown in fig. 4, and tighten the stud nuts.

2–Remove the distance block.

3–Unscrew retaining collar.

4–Remove stud nuts of fig. 4, permitting clutch to come apart.

5–Examine all parts for wear and replace worn parts.

6–Reassemble clutch, using compressor shown in fig. 4.

7–Place distance block in position and remove clutch from compressor.

8–Place friction ring, then clutch plate in flywheel, followed by the other friction ring.

9–Then put the clutch assembly in place, making sure that the dowel pins, or set screws, are in place on the inside rim of the flywheel, and that they fit into the slots of the driving plate.

10–Replace clutch, cover bolts, making sure the cover is on the same position as removed.

11–Replace transmission, drive shaft, etc.

12–Check up adjustment of pedals and clutch as outlined, and see that clutch brake is working all right.

13–Grease all parts and replace miscellaneous fittings.

CHART NO. 267—Care and Repair of a Dry Disk Type of Clutch—The Borg and Beck as used on many different cars—see page 543, also see pages 42, 43 and 842.

(Motor World.)

Usual troubles are: (1) stripped gears; (2) bearings worn permitting shaft to drop out of alignment (see page 732); (3) dogs worn and will not catch; (4) dripping oil from gear box.

The cause of dripping oil is due to either a loose gasket (fig. 2, chart 291), or to too much oil—running out at the bearing, or worn felt gasket sometimes used. Carry the oil level slightly below the secondary shaft. The lower gears will splash oil to all parts—see pages 203 to 205. (Note Overland uses grease—(see page 670—see Dodge 670, 666.)

Causes of the Other Troubles.

When dogs become worn (see part No. 139, page 48), so that they slip out of engagement, they may be dressed up or squared by grinding.

Noise: In gear boxes where shaft ends are supporter by single row ball bearings, with no provision for end thrust and are noisy—replace bearings.

Considerable wear in bearings will change the distance between centers of the transmission shaft—replace bearings.

Difficulty in shifting gears: Three reasons: (1) sticking or dragging clutch caused by heavy oil; (2) teeth of shifting gears burred; (3) considerable wear in bearings—throwing shaft out of line, which also causes noise.

End play—may be discovered by grasping the universal joint behind the gearset and attempting to move it forward or backward. If looseness is found, adjustment is needed. If end play is allowed to develop gears are likely to be stripped.

To determine cause of clashing gears: remove cover plate over clutch and, with rear wheel jacked and car in gear, let clutch in and out. If clutch continues to spin after it has been thrown out, look to clutch brake or too close an adjustment or heavy oil—causing gears to drag.

Note: Don't allow a nut or any chips of metal to lodge in transmission case—it will strip the gears if caught between the teeth. This also applies to engine and differential.

Don't use waste to wipe out the interior of a transmission—it leaves lint.

Speed Gear Ratios.

The gear ratios on transmissions of three speeds (Warner as example) is; (1st) speed, 2.5 to 1; (2nd) speed 1.7 to 1; (3rd) speed 1 to 1; (reverse) 3.4 to 1.

On four speed gear sets it is approximately, (1st) 3.6 to 1; (2nd), 2.07 to 1; (3rd) 1.32 to 1; (4th) 1 to 1; reverse 3.9 to 1 or 6.1 to 1.

The average ratios will be about as follows: 1st 3.24 to 1; 2nd 1.95 to 1; 3rd 1.19 to 1; 4th 1 to 1; reverse 4 to 1.

Rear Axle Pointers.

The three types of rear axles in general use are the Semi-floating, ¾ floating and Full-floating, as explained on page 33.

To find the type used on leading cars, see pages 543 to 546. On these pages, the make of axle as well as the type is given. For the Ford axle, see supplements. For the Marmon axle, a ¾ floating type, see page 32.

The S. A. E. distinction between the three types of axles is as follows:

Semi-floating—Inner ends of axle shafts are carried by differential side gears (differential carried on separate bearings). Outer ends of shafts are supported by bearings.

¾-floating—Inner ends of shafts carried same as in semi-floating. Outer ends of shaft supported by the wheels (only one bearing is used in each wheel).

Full-floating—Same as ¾-floating except that each wheel has two bearings (wheels do not depend on the shaft for alignment.)

Advantages of the semi-floating axle (by Packard Motor Car Co.) In the semi-floating axle, the wheel hubs can be made slightly smaller and because of location of bearings, the stresses in rear axle can be kept lower than in the full-floating type.

There is a slight advantage also in the bearings, as the full floating type have to use a bearing with a smaller ball, since it must fit around the rear axle tube. In the semi-floating type, the bearing has a smaller bore, and therefore, larger balls can be used as it has only to go over the axle shaft.

Another advantage is; the rear wheels can be more readily removed when replacments are necessary — wheels being replaced oftener than shafts. **Still another advantage claimed is that of lubrication**; as the outer bearings can be lubricated from the inside, and an oil retainer placed on the outside, whilst the full-floating type must have a separate supply of lubricant to the rear wheel bearings.

†Pointers on Removal of Differential.**

Removal of differential in a semi-floating axle and some ¾-floating axles; the entire rear axle assembly must be removed from the car. For instance, see Ford Instruction

The axle must be removed from car, as shown in fig. 1, page 675. The axle housing is usually divided in the center.

After housing and wheels are removed, the axle is then disassembled as shown in figs. 4 and 5.

†Removal of differential on all full-floating axles is done by withdrawing the axle shafts, leaving the wheels supporting the car and housing intact, as explained on page 679 (Studebaker). The differential can then be drawn from rear of housing by removing cover plate (fig. 1, page 677), or drawn from front of housing with drive shaft.

In the full-floating type the axle housing is seldom divided in the center.

How Axle Shafts are Fastened.

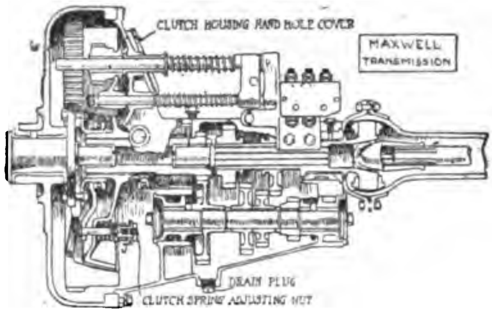
The semi-floating axle shafts are fastened to the differential by different methods. In some it is by means of a tapered pin, and key, others by split clamps which fit over heavy threaded portion of shaft end; still others by the use of Woodruff keys or split washers, as per Ford and per Maxwell (chart 278, fig. 5.)

The full-floating axle shaft is not fastened but is either square or "splined." Splines take the place of keyways, see fig. 7, page 680.

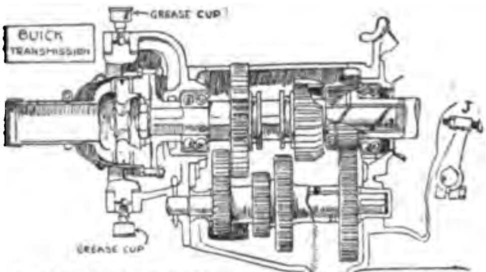
Removal of Wheels.

For removal of wheels see page 675. Pinion adjustments etc., see pages 678 to 679.

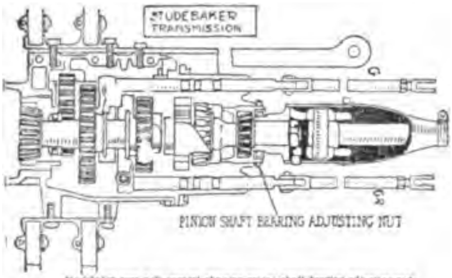
*See pages 544 to 546, "Specifications of Leading Cars," for types of axles, gearsets, etc. on leading cars. **See page 749 for the M & S locking differential. †See also, page 932 for the Dodge full-floating axle. †See page 583 for replacing a ring gear on a differential and one cause of noisy gears in rear axle housing.



Cutaway sketch of Maxwell gearset and clutch. The clutch-adjusting nuts are shown.



Buick gearset, showing grease cups over and under universal housing.



Studebaker rear axle gearset showing pinion shaft bearing adjusting nut.

Studebaker Transmission.

Studebaker gearset—The Studebaker sliding gear is a unit with the rear axle and is of conventional selective three-speed type. After a great deal of service the gearset pinion shaft may need adjustment in the suspending bearings.

To determine whether or not adjustment is needed endeavor to push the universal back and forth and if the shaft shows play where it enters the gearset case, it indicates that the roller bearings need taking up. The operation is performed through the pinion shaft adjusting nut. This nut is locked by a pawl and the pawl, in turn, is locked by the lock bolt which holds the adjusting nut. Loosen the nut on this bolt and the pawl can be removed from the adjusting nut.

To make the adjustment, turn out the adjusting nut until the play between the shaft and gearcase disappears. It is not necessary to draw the nut up excessively tight When the operation is completed, lock the units in the inverse operations by which they were unlocked.

A light gearset grease is advised for oiling.

Buick Transmission.

Buick gearset—The main shaft of the Buick gearset is ball-bearing mounted. To lubricate, it should be filled with steam-cylinder oil, which is about the heaviest flowing oil obtainable, and to do this the filler cap on the right side of the gearset case must be removed and the case filled to the level of the opening. Above model is the type used on all models prior to model K. There are some improvements on the model K.

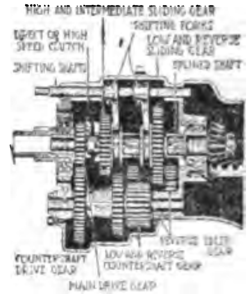
Maxwell Transmission.

The Maxwell gearset is conventional sliding gear, three speeds forward and reverse. Bearings are non-adjustable, but if properly cared for should not need renewal.

To oil the gearset, remove the filler plug in the top of the gearcase cover and pour in a very heavy flowing oil, preferably a steam cylinder oil, **until the lower or countershaft gears are about half covered.** When the case is empty this will require about 1 quart of oil. Do not use hard grease.

The clutch used on the Maxwell is a cone type faced with a fabric composition, and runs in a bath of oil. To remedy slipping in the clutch, providing that the fabric facing has not become worn down excessively, remove the hand-hole cover from the forward top of the gearset case and take up tension on the three springs. Each spring should be tightened an equal amount. A grabbing clutch probably means lack of oil or possibly that there is too great a tension on the springs.

The clutch housing should contain from 1 to 1½ pints of lubricant. Ordinary motor oil will give the best results. This oil may be inserted through the inspection plate on top of the clutch housing and should be renewed every 2,000 miles, the old oil being drained out through the drain plug on the bottom of the housing. It is well to flush the clutch with kerosene. See page 675—Maxwell axle.



*Overland Transmission.

***Overland gearset:** Twice a season at least, the gear box should be opened and filled with kerosene or gasoline and the resulting thin solution drawn off through the opening in the bottom of the gear case. When the case is cleaned, pack with grease, replace the gasket carefully, and screw down the cover.

In disassembling the transmission, the transmission shaft goes out first, the countershaft next, and the reverse gears last.

The right way to replace transmission bearings: The annular ball bearings of the transmission should be replaced as follows:

Place a piece of lead pipe over the shaft and against the bearing in such a manner that the blow will be borne by the outer raceway of the bearing, that is, the one seating in the transmission housing. If the inner or smaller raceway, or the end of the shaft, be hammered upon, the blows are transmitted to the balls themselves and in not a few cases they are broken. (see chart 277).

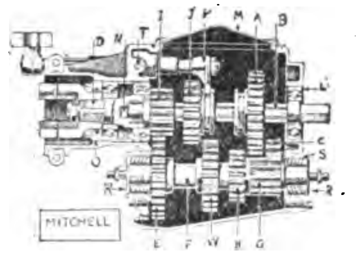
**Dodge Transmission.

—**The Dodge gearset** main sliding-gear shaft is mounted on ball bearings at either end and looseness means replacement of the bearings. The countershaft is mounted on bronze bearings. If the gearset is kept properly lubricated with clean oil, none of these bearings should need replacement in a good many thousand miles of driving. Not more than 2 quarts of gearset lubricant should be used in the case. The level should be inspected every 1,000 miles and, if it **has fallen so low that the gears on the main shaft do not dip well into the lubricant,** the supply should be replenished so that they do. **The level should be kept ½-inch below the main sliding-gear shaft**—see also pages 932, 931.

CHART NO. 268—Transmissions or Gear Sets—How to Care for and Adjust.

*Overland transmission is placed as a unit with the rear axle. **See pages 666, 931, 932, for Dodge transmission, and page 689 for Dodge brake.

Removing, Disassembling and Assembling Transmission —Mitchell as an Example.



To remove transmission. Place jack under drive shaft housing to prevent the transmission from falling. Remove and slide back the shell covering clutch hub. Turn clutch until one slot in clutch hub is up and the other down. Remove the two large hexagon nuts holding the transmission to the main cross frame member. By lowering the jack the front of the transmission can be lowered to the floor. Remove the eight bolts holding transmission to drive shaft housing and the transmission can be removed.

To disassemble transmission. Remove main shaft "B" and sliding gears "A" and "J." After the transmission has been taken out of car, the main shaft "B" with the bearing "L" can be withdrawn from the transmission case without disturbing any other part. After top cover plate "M" is removed the two sliding gears "A" and "J" can be lifted out of the case. In drawing out the main shaft care should be taken that the thrust washer "N" does not drop into the case. A good suggestion is to rest the transmission case on the forward end.

To remove gear and spindle. To remove gear and spindle "D" and "I." Remove the small plate in the front side of transmission case (not shown in illustration) through this opening unscrew the collar "O." Gear and spindle with universal joint complete can now be withdrawn. When putting back this part be sure the thrust washer "N" is put back in place.

To remove sub-shaft and gears. After the main shaft and the two sliding gears have been removed as above, take out gear shifting rods "P"; remove reverse idler gear "C" by driving out the short shaft upon which the gear revolves. (Don't attempt to tap inward, this must be tapped outwards from the inside.) (See below, to remove reverse idler gear.) By removing the plug at the forward end of the transmission case in line with the shaft a steel rod can be inserted and the short shaft driven out. Remove the two bearing caps "R" and "R" and move back the sub-shaft "F" until bearing "S" comes from the case. Remove bearing "S" from the shaft. By lifting up the front end of the subshaft it can be taken out through the top of the case.

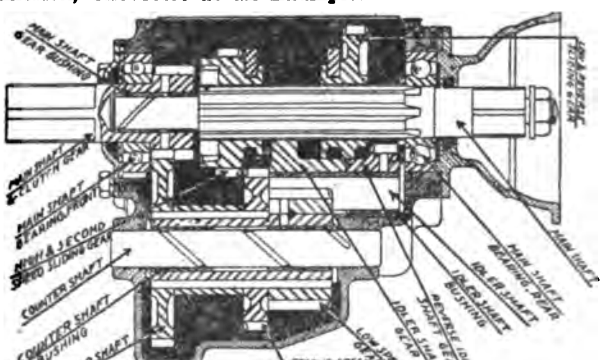
To remove reverse idler gear. After, the large cotter pin through the reverse idler gear shaft at the outside of the transmission case is removed. As an accessibility feature the reverse idler gear can be removed without disturbing any other part. By removing the plug at the forward end of transmission case in line with the short shaft a steel rod can be inserted through the hole and the short shaft driven out.

When reassembling you must be careful that all gears are in the same relative position in which they were originally.

In a socket at the forward end of the case are placed two plungers under the tension of a spring. When the sliding gears are in their proper position these plungers fall into recesses on the gear shifting rods, holding the gears in position. When the gear shifting rods are replaced the plunger can be pushed down so the rods will enter by unscrewing plug "T."

After the transmission is reassembled, test it out before it is reinstalled in the car. Put it in different speeds to see that is it assembled correctly.

Care of Transmission, Chevrolet as an Example.



The transmission is the regular selective type, having three speeds forward and one reverse. The clutch is explained in chart 263.

To lubricate, fill every 1,000 miles with No. 600-W steam cylinder oil, not grease, so that oil level stands at bottom of the upper or splined shaft.

To clean: Once every 2000 miles wash out transmission with kerosene to remove any particles of metal worn off the gears or other foreign substances. To do this remove the drain plug at the bottom of the transmission case and allow the oil to drain off, after which flush out thoroughly and refill with oil.

Chevrolet Rear Axle.

This is almost a true semi-floating type of axle. The bearings however are not direct on the axle on the outer end, but are between the housing and rear wheel hub (see fig. 33, chart 270), therefore it is termed a ¾ floating type (see page 669 and 33).

How to remove the rear axle assembly:. Jack up the car and remove bolts and clips holding springs to axle housing. Disconnect all brake rods from foot pedals to rocker shaft mounted on the propeller shaft housing, and slide entire assembly from under the car.

How to remove the propeller shaft: Slide the axle assembly from under the car and remove nuts holding the propeller shaft housing to axle housings. The propeller shaft housing assembly can then be lifted off. Remove the pinion shaft bearing lock stud (fig. 33, chart 270), and with a lead hammer or piece of wood held against the upper or universal joint end of the propeller shaft, drive the shaft and bearings from the housing.

Extreme care should be used not to batter the end of the shaft. If a few smart blows do not start the bearing, examine it carefully. Probably a burr is holding it or the inside edge of the housing may have become battered over. The drive pinion and bearings can then be removed by unscrewing the nut on the end of the propeller shaft.

Replacing drive pinions: Should it become necessary to replace the drive pinion, extreme care should be exercised to see that the tapered hole of

CHART NO. 269—Removing and Disassembling a Transmission—Mitchell and Chevrolet as examples

—continued from Chart 269.

the gear fits the taper on the shaft snugly and at all points. Always, before putting the new pinion on the shaft, remove the cotter pin holding the adjusting nut and turn the nut back two or three turns. As it is impossible to machine two tapered holes exactly alike, one gear may "go on" a little farther than the other, so if the adjustment were not changed the gear would "shoulder" against the bearing before obtaining a good seat on the shaft.

It is a good plan to "try" the fit of the gear on the shaft before finally assembling. The best way is to secure a little Prussian blue and spread it thinly around the bore of the gear. Press the gear on the shaft, then remove and note the marks made on the shaft. If the "bearing" is uneven smear a little valve grinding compound on the shaft and with a reciprocating motion "grind" the gear to its seat. Much depends upon securing a good snug fit, so take your time, as it is a good insurance against roadside repairs. After having secured a good fit, securely lock the nut and spread the cotter pin. Before fitting the gear examine the key. If this is loose in the shaft or worn replace it with a new one. The adjusting nut should then be set up and securely locked with a cotter pin. Care must be used not to get the adjustment too tight; however, it should be snug. If the holes for cotter pin will not "line up" without getting the bearing too tight or too loose, make a washer of tin or brass and insert betwen the nut and center thrust bearing washer.

In replacing the propeller shaft and bearings in the propeller shaft housing care must be used not to crowd the bearings. Be sure to line up the hole in the bearing sleeve with the hole in the housing for the pinion shaft bearing lock stud, after which replace the stud.

How to Remove Differential Assembly.

Remove the propeller shaft housing assembly and rear wheels. The axle housing is in two parts, right and left, bolted together in the center. Remove the bolts and slide the housings off the shafts.

The differential gear case is in two halves and can be separated by removing the clamping bolts, after which the axle shafts with the main shaft gears can be withdrawn.

The differential main shaft gears are keyed and pinned to the axle shafts. After removing the pins the gears can be pressed off the shafts.

In reassembling the differential be sure that the two fibre thrust washers are fitted into the recessed ends of the main shaft gears . (see fig. 5, chart 278.) After tightening the clamping bolts be sure to lock them with a wire passing through holes in their heads.

Before sliding the axle housings back on the shafts, examine the differential thrust bearings. If they are worn or roughened, replace them, as these must be in good condition, otherwise there is danger of broken gears.

Once every 2000 miles it is a good plan to test the thrust bearings. To do this jack up the rear of the car so that the wheels clear the ground. Grasp the wheel and push in and pull out. If any play exists it represents the amount of wear on the thrust bearings. If this is more than $\frac{1}{32}$ of an inch the axle must be disassembled and new thrust bearings installed.

After the axle is assembled remove the filler plug and pour oil into the housing until it runs out of the filler plug hole. No. 600W steam cylinder oil is the best for summer use and light cylinder oil for freezing weather.

Before connecting the axle with the transmission, pack the universal joint with cup grease.

How to Remove the Universal Joint.

With the axle removed from under the car, take out the five cap screws holding the joint ball retainer collar and pull the ball joint from the socket. Remove the four clamp screws holding the two universal joint rings together (fig. 34) and separate the rings. The nut holding the universal joint yoke to the transmission shaft can then be removed and the yoke pulled off the shaft.

How to Adjust Chevrolet Brakes.

It is important that the brakes be adjusted evenly, that is, that when applied both grip the brake drums with the same pressure and at the same time.

The rods connecting the foot pedals with the brake shaft on the propeller shaft housing are provided with turnbuckles. (See fig. 19, chart 264.) By turning these the rods can be shortened or lengthened, which in turn tightens or loosens the brake bands.

Caution: Do not adjust the brakes too tight, otherwise they will "drag," using up power and wearing out the brake linings in a very short time.

Should one brake "grab" or take hold too quickly, remove the brake operating cable yoke pin on that side and shorten the cables by screwing up the yoke ends.

Care should be taken to see that both brakes are adjusted alike as serious harm will result if one wheel does all or most of the braking; it will cause the car to skid more easily and cause exessive wear on the tire. It also puts an undue strain on the axle parts.

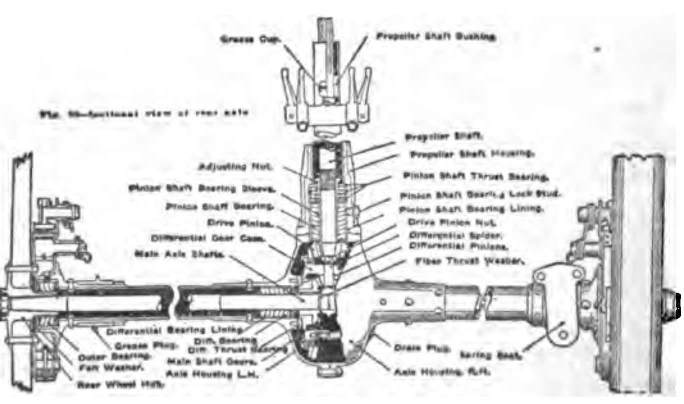


Fig. [illegible]—Sectional view of rear axle

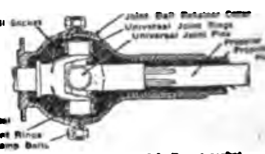

Fig. 34—Sectional view of ball and socket

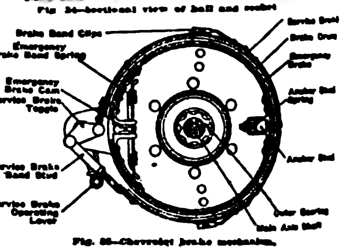

Fig. [illegible]—Chevrolet brake mechanism.

CHART NO. 270—Rear Axle (¾-floating type) and Differential—How to Remove and Replace Parts—Chevrolet "490" as an example.

Chart No. 271 omitted (error in numbering).

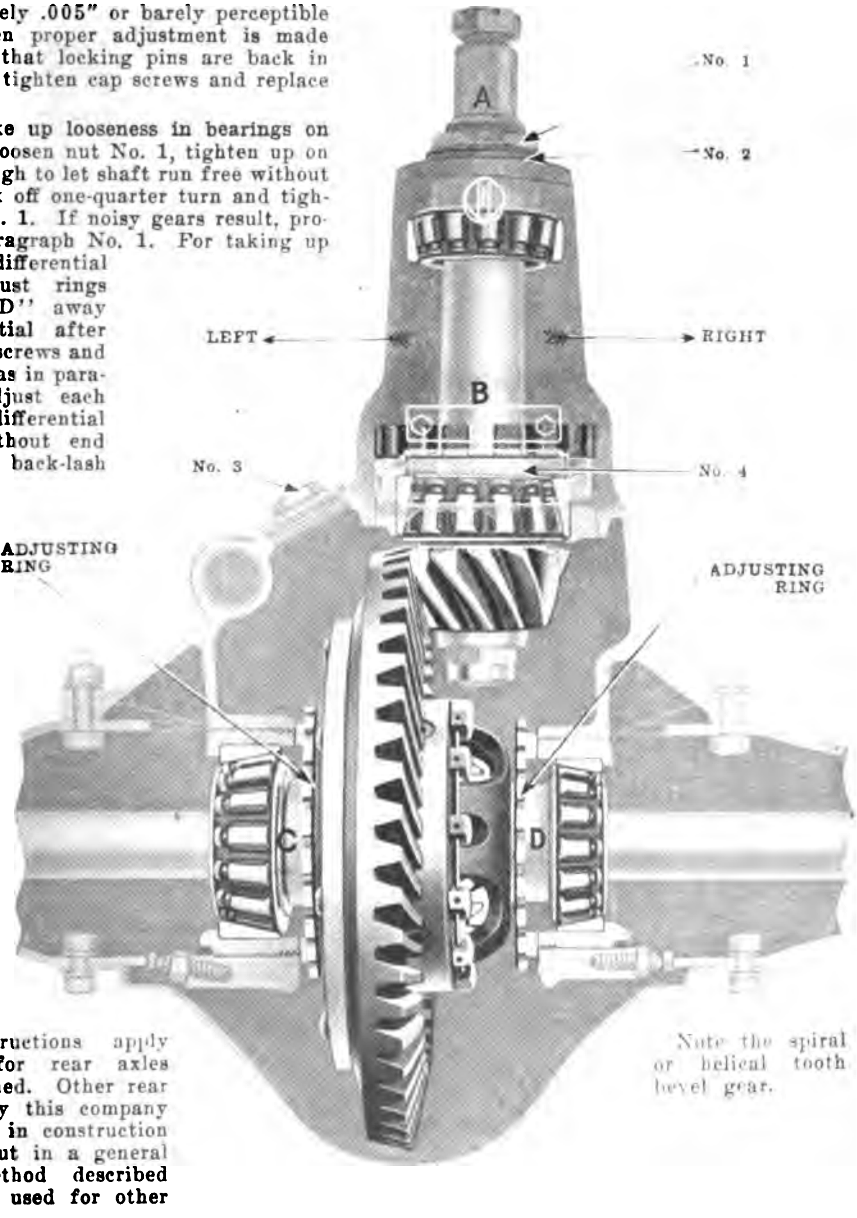
There are three conditions that make adjustment of gears advisable. These are: 1—Objectionable noise; 2—Excessive backlash; 3—Looseness between the bearings on the pinion shaft or at the differential.

1st.—To eliminate noise, loosen nut No. 1 at "A" and then loosen nut No. 2. **Remove the** cover at "B" and loosen clamp bolt No. 4. Turn the slotted adjusting cup towards the **left,** one notch and tighten up nut No. 2, then nut No. 1 just enough to let the shaft run **freely** without end play. If this lessens the noise, loosen nuts No. 1 and No. 2 and turn **adjusting** cap another notch and repeat this operation until quietest point is found. If noise **increases,** adjust in opposite direction. When final adjustment is made so that pinion shaft **has no** end play, back off nut No. 2 one-quarter turn and tighten up ou nut No. 1. Bend **washer** over one flat of each nut, tighten up clamp bolt No. 4 and replace cover.

2nd—To take up backlash, back adjusting ring at "D" towards differential, (in order **to allow** the whole unit to slide to the right) and turn ring at "C" against bearing cap **which** will force gear towards pinion. These rings have right hand thread. Before turning **rings,** loosen cap screws in bearing cap one-half turn after removing locking wires. (see chart **272-A.**) Proper amount of backlash should **be approximately** .005" or barely perceptible **looseness,** when proper adjustment is made **make** certain that locking pins are back in **slots** of rings, tighten cap screws and replace **locking** wires.

3rd—To take up looseness in bearings on **pinion shaft,** loosen nut No. 1, tighten up on **nut** No. 2 enough to let shaft run free without **end play,** back off one-quarter turn and tighten up nut No. 1. If noisy gears result, proceed as in paragraph No. 1. For taking up **looseness** in differential **bearings,** adjust rings "C" and "D" away **from** differential after **loosening** cap screws and **locking** wires as in paragraph 2. Adjust each **ring** until differential **runs** free without end **play** and if back-lash **results,** proceed as in **paragraph** 2.

4th—If gears are so far out of mesh that no result can be obtained through method described above or new gears have to be placed in axle, remove peep hole cover No. 3, for observation and set gears with backs flush, as a starting point, and proceed as above.



These instructions apply **particularly** for rear axles **above** mentioned. Other rear **axles** made by this company **differ** slightly in construction **from** these, but in a general **way** the method described **above** can be used for other **axles** also.

CHART NO. 272—Adjustment of Gears, Timken Rear Axles. Above applies to Timken **full-floating axle,** numbers 5741, 5742, 5395, 5396, 538 and 574. McFarland (5742); Hal (5395); Daniels (5396); Dorris (5396). (See chart 280B, Adj. Timken Bearings).

Chart No. 271 omitted, error in numbering. *See also, Dodge Full Floating Axle, page 932. See page 583, how **to rivet a ring gear** (the large bevel gear on differential) to differential flange.

Adjusting Timken Rear Axle—Type Indicated Below.

The same conditions make adjustment necessary as mentioned in chart 272.

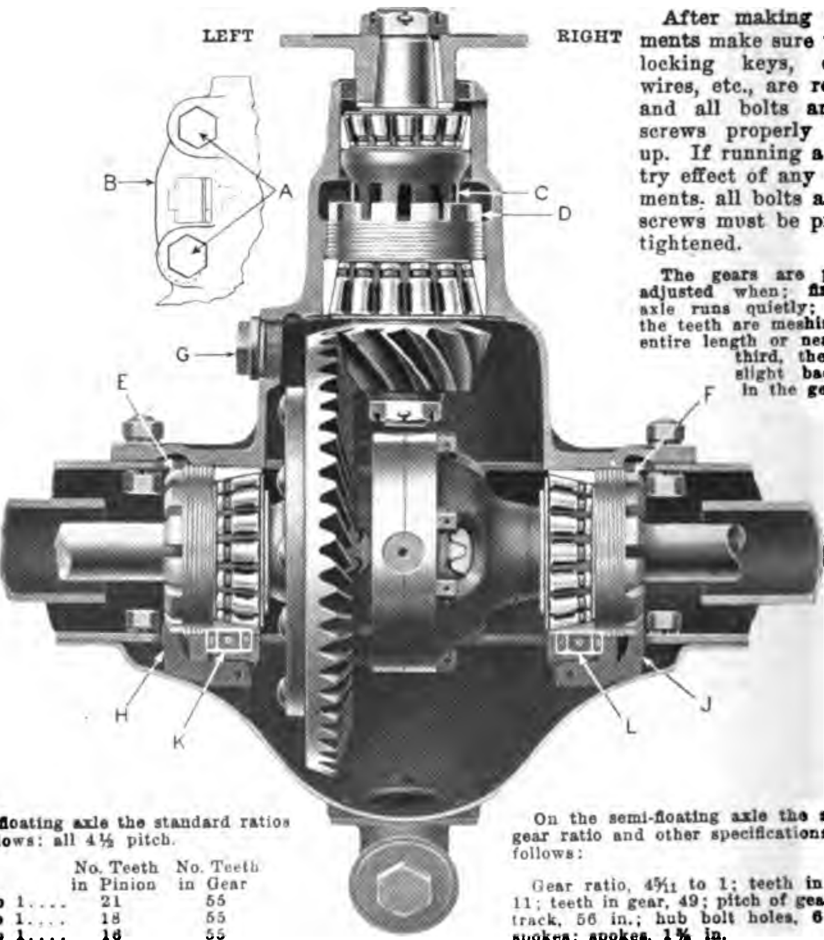
1st—Before making adjustments for elimination of noise or backlash, take up all looseness, if any, in bearings. To do this, remove bolts "A" and locking key "B." Turn slotted ring "C" towards right, while holding ring "D" in its original position, until bearings are free from end play, at the same time allowing pinion shaft to turn free. To take up differential bearings, remove locking wire in cap screws "L" and loosen screws one-half turn. Release locking finger "J" and turn right hand adjusting ring "F" towards differential until bearings are free from end play, at the same time allowing differential to turn freely.

2nd—When adjusting to eliminate noise, remove bolts "A" and locking key "B" as above and turn rings "C" and "D" one slot towards the left and repeat until quietest point is found. If noise increases, adjust in the opposite direction. Always turn rings "C" and "D" together when adjusting for this purpose by using a tool broad enough to engage slots in both rings.

3rd—When adjusting to take up backlash in gears, remove wire and loosen cap screws "K" "L" one-half turn. Release locking fingers "H" "J." Back adjusting ring "F" away from differential and turn adjusting ring "E" towards differential (right hand thread on both) until gear is forced towards pinion so that it **has about .005 inch backlash** or barely perceptible looseness.

If gears are so far out of mesh that no results can be obtained through method described above, or new gears have to be placed in axle, remove peep hole plug "G" for observation, and set gears with backs flush, as a starting point, and proceed again as above.

If noise results from taking up loose bearings, proceed as in 2nd and 3rd paragraphs.



After making adjustments make sure that all locking keys, cotters, wires, etc., are replaced and all bolts and cap screws properly drawn up. If running a car to try effect of any adjustments, all bolts and cap screws must be properly tightened.

The gears are properly adjusted when: first, the axle runs quietly; second, the teeth are meshing their entire length or nearly so; third, there is a slight back lash in the gears.

OIL FILLER

On the floating axle the standard ratios are as follows: all 4½ pitch.

Ratio	No. Teeth in Pinion	No. Teeth in Gear
2-13/21 to 1....	21	55
3-1/18 to 1....	18	55
3-7/16 to 1....	16	55
3-2/3 to 1....	15	55
3-13/14 to 1....	14	55

On the semi-floating axle the standard gear ratio and other specifications are as follows:

Gear ratio, 4 5/11 to 1; teeth in pinion, 11; teeth in gear, 49; pitch of gears, 4⅝; track, 56 in.; hub bolt holes, 6 for 12 spokes; spokes, 1⅝ in.

CHART NO. 272A—Adjustment of Gears in Timken Rear Axles. Above applies to Timken semi-floating or fixed-hub-type axles, numbers 5230, 5240, 5241, 5252 and 35C. Cadillac (5752); Hudson (5241); Jordan (5241); Westcott (5240); Chalmers (35).

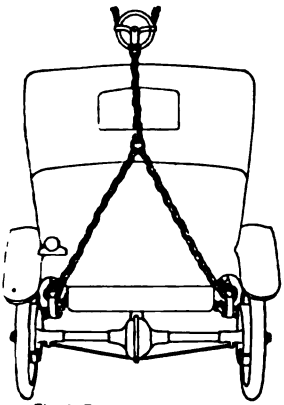


Fig. 1—The car is readily lifted by a chain block and sling. One man can do the work, and the car is held without danger of falling

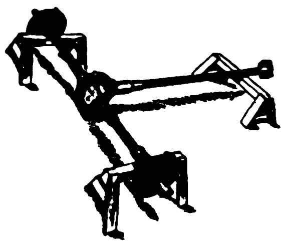

Fig. 2—Three horses form a serviceable axle stand, though a special stand could readily be made. Never attempt to dismantle or assemble a part on the floor but get the work up where it is accessible and clean

Fig. 3—The feature of this rear wheel puller is that the screw is hardened tool steel, loosely threaded into the cap. The endplay permits a sharp blow on the screw to loosen the sticking wheel

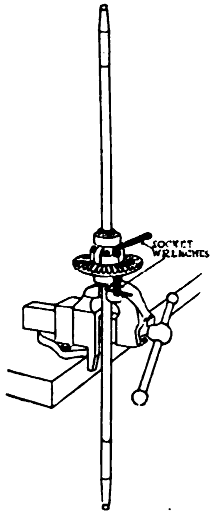

Fig. 4—The differential may be most readily assembled and adjusted, if caught in the vise in this manner. Two socket wrenches are used to do the work

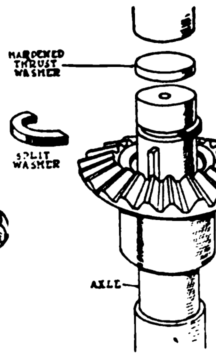

Fig. 5—Don't attempt to remove the side bevel gear from the axle drive shaft until the split washers have been removed in the manner shown

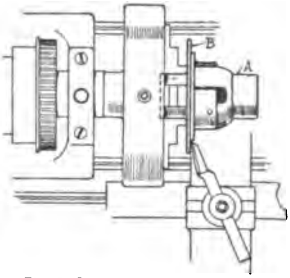

Fig. 6—Breakage of the ring gear usually springs the differential housing flange. By catching the entire housing in the lathe and trueing it up by the surface (A), the ring gear seat (B) may be refaced with a light cut

Fig. 7—In testing the adjustment of the differential gears, grasp the assembly in this manner, and turn the axles in opposite directions. They should turn freely all around

Evidence of Trouble.

1–Any excessive grinding or humming indicates that the gears are either worn, broken, or poorly adjusted.

2–An intermittent catch occurring perhaps only every 100 miles. This indicates that parts of one or several teeth are broken, and are catching in the gears.

3–Actual failure of the axle to operate.
(Any of these necessitates a removal of the axle from the car, tearing down and replacement of defective parts with readjustment).

To Remove Axle.

1–Block front wheels.

2–Raise rear of car as shown in fig. 1.

3–Disconnect brake rods at the point of connection to the brakes.

4–Remove clips holding axle to springs.

5–Draw axle and housing out to the rear. The driveshaft slips out from the universal and must be caught to prevent possibility of injury to the splined end.

6–Place the axle on three horses arranged as shown in fig. 2.

7–Remove hub caps.

8–Remove axle nuts.

9–Using puller shown in fig. 3, remove wheels.

10–Remove torque tube and driveshaft. Save the gasket.

11–Catch the grease in a pail.

12–Remove nut from one end of axle truss rod.

13–Remove differential housing bolts.

14–Pull off the differential housing halves.

15–Place differential in vise as shown in fig. 4; pull cotter pins from bolt ends and remove differential casing nuts, allowing the two halves to come apart.

16–Remove split washers from end by driving the gear down as shown in fig. 5.

17–Remove bearings and all parts, wash and clean with gasoline.

General Repairs.

1–After cleaning examine all parts for wear. Go over gear teeth, to see if any are broken, or worn. Also note whether driveshaft bevel gear has been wearing evenly along the teeth. The face of the teeth should be bright all over. Any breakage or perceptible wear necessitates a replacement of the gear.

2–Draw driveshaft from torque tube. Clean, and examine bearings.

3–If the axle has been disabled by a collision, the shaft should be caught between lathe centers, tested, and trued up, if bent.

4–If any serious bend is found in either of the shafts, the two halves of the rear axle housing should be bolted together, tested for alignment in the lathe, and straightened.

5–When the large ring gear on the differential must be replaced, its bearing on the differential casing should be trued up in the lathe, as shown in fig. 6.

—continued in chart 274.

CHART NO. 273—The Disassembly and Assembly of Maxwell "25" Rear Axle and Differential.
This axle is a ¾-floating for the same reason as the Chevrolet, chart 270, explained in chart 269. It has the appearance of a semi-floating, but on account of the bearing being between hub of wheel and housing, and bearings supporting differential, it is a true ¾-floating. Axle assembly must be removed and housing stripped from axle. By referring to Ford supplement, chart 328, a true semi-floating axle is shown—outer end of axle shafts connect direct to wheels with Woodruff keys.

—continued from page 675.

The Reassembly.

1–Replace the shaft bearings, differential housing halves, and shaft gears, making certain that the split washers are in place.

2–Replace differential cross gears on differential cross and holding shaft in vise as shown in fig. 4, bolt halves together. (Be certain that the thrust washer is in place between the ends of the shafts.)

3–When the halves are bolted together there should be about 1-64 in. end play between the two halves of the shaft. If tight, take differential apart and file a little from the end of each shaft.

4–Rebolt the halves, and holding as shown in fig. 7, turn the two shafts in opposite directions. The axles should turn easily all the way around.

Note—If sticking is noted in any place, catch assembly in vise (fig. 4) and with tang of a file, find by feeling, which cross gear is sticking. If new cross gears have been installed, try changing the sticking gear for a new one. Or if new side gears installed, try changing side gears.

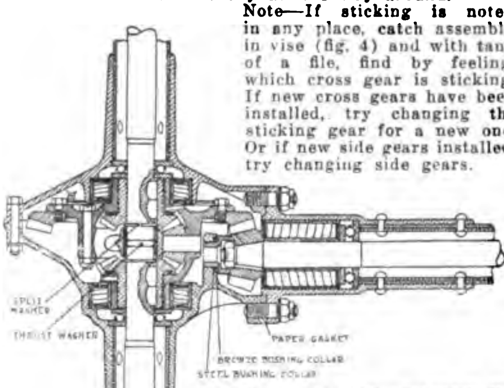

Fig. 9—The points on the differential assembly that should be particularly watched, are indicated in the above drawing

5–Replace the cotter pins in the differential casing. Clip the ends over, away from the cross gears.

6–Using horses shown in fig. 2, slip the halves of the rear axle casing in place after packing all bearing and gears with nonfluid oil.

7–Bolt the halves together. (Do not pull one nut up tight until the others are snug.)

8–Now get the torque tube and driveshaft ready for assembly. The shaft should turn freely in the housing. Bearings should be packed in grease.

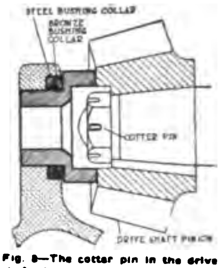

Fig. 8—The cotter pin in the drive shaft pinion lock nut should not interfere with the thrust bushing, and the bushing collars should be inserted in the manner shown

(Note—If a new driveshaft pinion has been fitted, make certain that the bent ends of the cotter pin in the end of the driveshaft do not interfere with the thrust bushing. (see fig. 8.)

9–Fill axle housing with a good grade of non-fluid oil until the ring gear dips well into the oil.

10–Place first the bronze washer on to the drive pinion thrust bushing, then the steel washer, and insert the bushing into the rear axle housing.

11–Replace the torque tube gasket and slip the torque tube and driveshaft into the axle. Bolt in place.

12–When all bolts are tight; the driveshaft should turn freely under the action of a pipe wrench. If any sticking is noticed, additional gaskets should be placed between the torque tube and the axle. If any slack exists in the gears, the gasket should be replaced by one made of thinner paper.

13–Make certain that the brake levers work freely. Oil well. Note whether the brake bands are wearing evenly and are in good condition. Reline, if necessary.

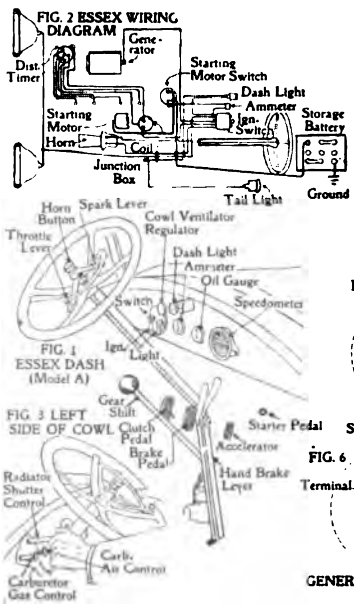
14–Replace the wheels. Fill hub caps with medium cup grease.

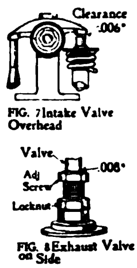
(Note—It is always advisable to grease the rear springs with graphite and grease at this point.)

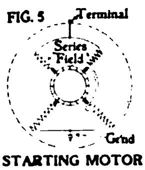
15–Roll axle beneath car and with one man guiding the driveshaft, slip it into the universal. The splines may not line up at first and hence it may be necessary to crank the engine slowly by hand until the two slide together.

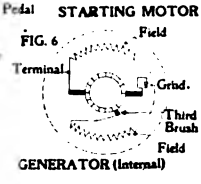
16–Let the car down onto axle; 17–Bolt spring shackles to axle; 18–Reconnect brake levers.

Description of The Essex Model "A" Car.









Specifications: See page 544. **Valves**: Inlet (fig. 7) overhead, operated from the side. **Exhaust** operated from the side (fig. 8).

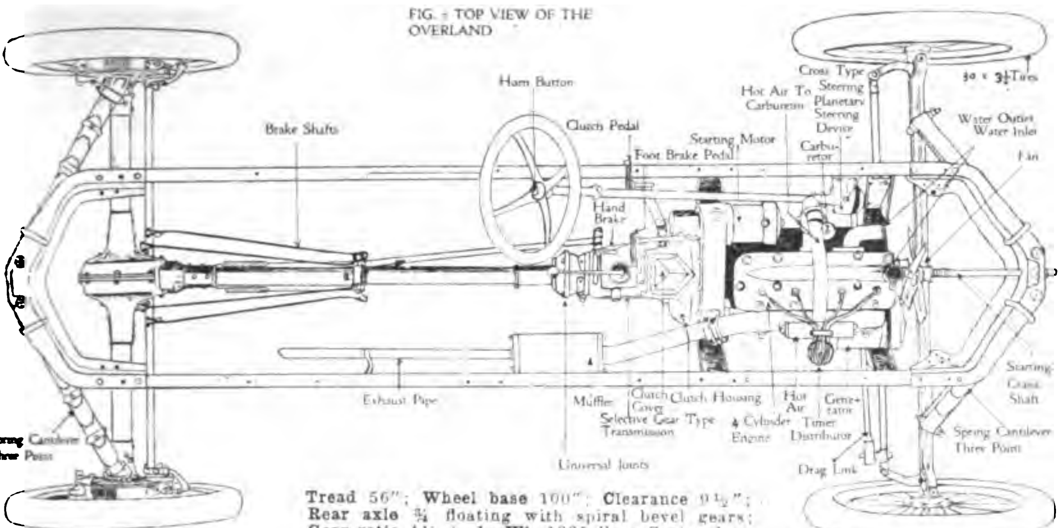
Electric system: Delco three-unit single wire system. Starting motor drives through flywheel (see internal wiring fig. 5). **Generator driven from** right side of engine. Third brush regulation (see fig. 6). **To chane output of generator, shift 3rd** brush. 16 amp. is maximum.

Ignition: Delco closed-circuit timer and distributor driven at ½ crank shaft speed with automatic advance. Condenser and ignition resistance unit mounted on side of timer—see page 378 for purpose of ignition resistance unit.

Transmission: Selective type, three speed and reverse. Gear shift same as fig. 1, page 490. **Clutch**: Multiple disc lubricated type with cork inserts. **Rear axle**: Semi-floating. **Carburetor**: Pneumatic principle, similar to figs. 1, 2, 3, page 183.

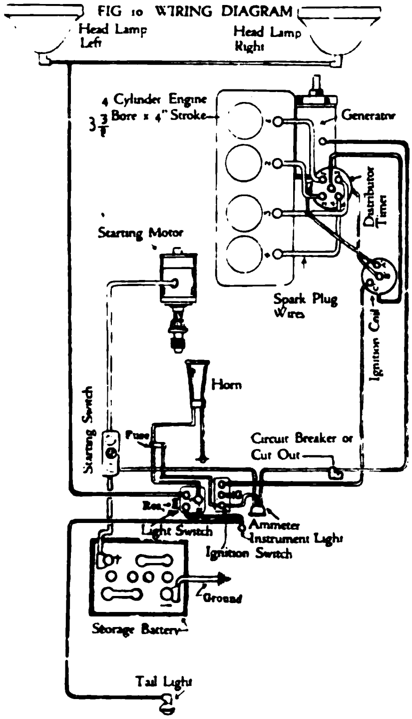
Adjustment of timer gap .018", spark plug gap .030", firing order 1, 3, 4, 2.

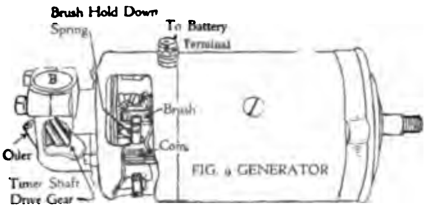
Ignition timing: Place spark lever full advanced. Turn engine until No. 1 piston starts to come up on compression stroke and stop when D. C. 1-4 mark on fly wheel is in line with pointer on fly wheel of engine, then loosen timer adj. screw in center of distributor shaft and turn breaker cam so that rotor button will be in position under No. 1 high tension terminal or that which leads to No. 1 cylinder, when the distributor head is down in place. Locate the breaker cam carefully in this position so that when the slack in the distributor driving gears is rocked forward the contacts will be opened by the breaker cam, and when the slack in the gears is rocked backwards, the contact will just close. **Valve timing**, page 542.



Tread 56"; Wheel base 100"; Clearance 9½"; Rear axle ¾ floating with spiral bevel gears; Gear ratio 4½ to 1; Wt. 1825 lbs.; Spring base 130".

FIG 10 WIRING DIAGRAM





Generator is driven from right side of engine by helical gears, from crank-shaft.

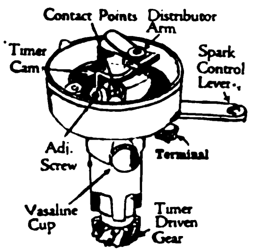


FIG. 6 TIMER

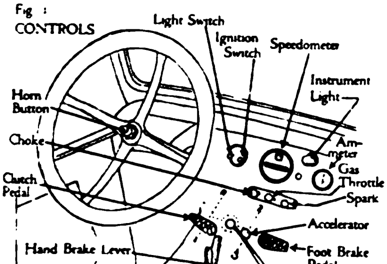
Timer is driven from armature shaft through opening B, fig. 9, by helical drive gear.

Fig. : CONTROLS



Note spark and throttle control on cowl board.

Specifications Overland 4.

Engine: 4 cyl. 3⅜" bore x 4" stroke. S. A. E. h. p. 18. Actual 27. Three bearings. Lubrication, splash, and centrifugal force. Oil thrown from periphery of fly wheel which feeds under this pressure to crankshaft bearings. Monobloc L-type cylinders with separate head. Helical timing gears.

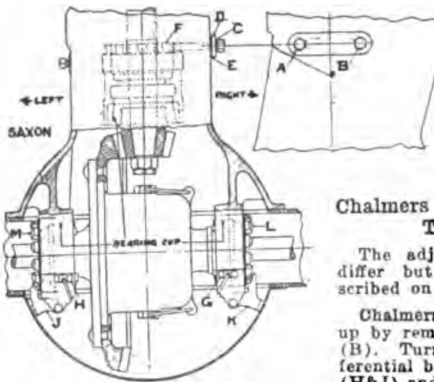
Valves on the side. Size 1⁹⁄₁₆" di. head; ⅜" di. stem; 1⅜" di. in clear; 45° seat; ⁷⁄₃₂" lift. Cast iron head welded to steel stem. **Rings;** 3, and are 3⅜" di. x ³⁄₁₆" wide.

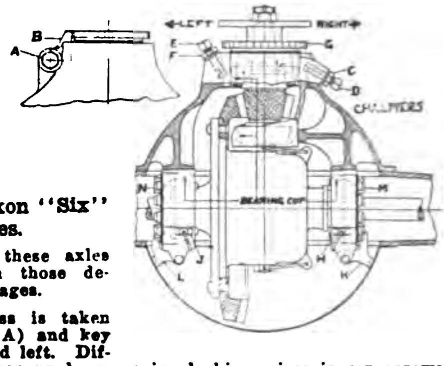
Valve timing: Inlet opens 0.97" past upper d. c.; inlet closes 2.83" past lower d. c.; exhaust opens 3.64" before bottom and closes 0.81" past top d. c.

Cooling: Thermo-syphon. Capacity of radiator 3¾ gal.
Carburetor: Tillotson ¾" special.

Electric system: Auto-Lite two-unit, six-volt starting and lighting system, with Bendix drive. U. S. L. Battery, 6 volt, 80 amp. hour. Model GK 1001 generator with 3rd brush regulation. Starting motor model MG 1001.

Ignition: Connecticut timer and distributor driven from armature shaft (figs. 9 and 6). **Transmission:** selective type, 3 speed and reverse. **Gear shift** same as fig. 1, page 490. **Clutch:** Borg and Beck single plate lubricated type. **Gasoline feed,** gravity, 10 gal. tank. **Steering:** Planetary type, similar to fig. 37, page 693.





Chalmers "35;" Saxon "Six" Timken Axles.

The adjustment of these axles differ but little from those described on preceding pages.

Chalmers: Looseness is taken up by removing bolt (A) and key (B). Turn (G) toward left. Differential bearing is taken up by removing locking wires in cap screws (H&J) and loosen ½ turn. Release (L&K) and turn (M) towards differential. To eliminate noise, loosen (A, F & C). Back off (D) one or two turns and take up on (E) about ¼ turn. If noise is increased, adjust in opposite direction by backing off screw (E), screw in on (D). Be sure (E & D) are locked when finished. To adjust back lash remove wire and loosen cap screws (J & H) ½ turn. Release (L & K). Back (M) away from differential and turn ring (N) towards differential as per instructions in chart 272-A.

Saxon: To eliminate noise, remove screw (A & B) and cover plate (D). Turn (F) one slot towards the left and repeat until quiet—a screw driver can be used. To remove back lash, remove wire and loosen (H & G) ½ turn. Release (K & J.) Back adjusting ring (L) away from differential and turn (M) towards differential until back lash is taken up.

Oil Leakage From Rear Axle.

Preventing the grease or oil in the differential housing from making its way to the brake bands and thus causing inefficient braking was a big problem to manufacturers some years ago, but the difficulty has been overcome largely in all the present types. In all the axle housings on the market, some precautions is taken to prevent this leaking and nine cases out of ten when leak occurs despite this, the condition is caused by placing too much oil or grease in the housing.

1—Showing the double felt washer construction used on National cars; 2—Hess axles have a bent axle tube and a felt washer, making the path of the oil upward in the tube, and only when under abnormal pressure will it work out through the bearing to the washer.

Fig. 3: A sleeve is placed around each axle shaft on the Timken, and when oil is thrown to one side the sleeve acts as a pocket and retains the oil.

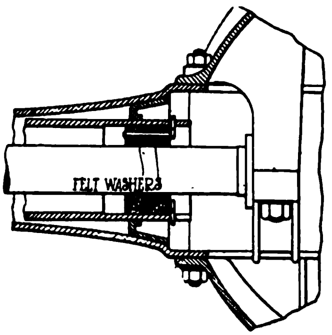


Fig. 1.

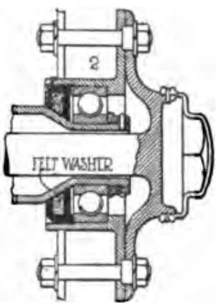

Fig. 2.

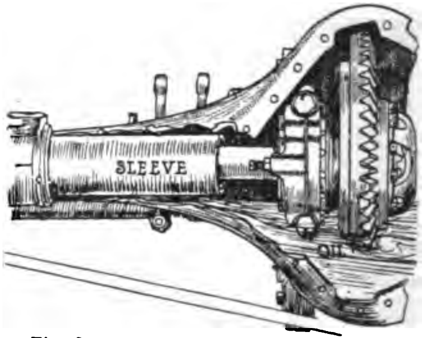

Fig. 3.

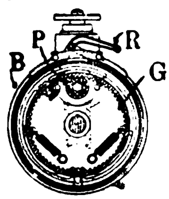
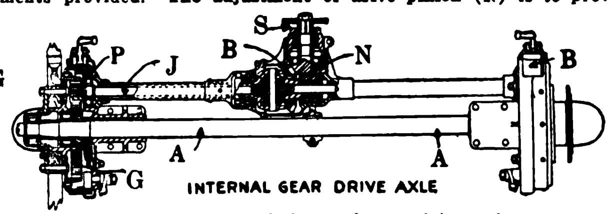
The Internal Gear Drive Axle.

This rear axle is used extensively on trucks and differs from usual type in that the rear axle (A) is solid. An internal gear (G) is on the inside of wheel hub (D). A spur gear pinion (P) drives this gear (G) which revolves the wheel. The spur gear drive pinion (P) is driven by a jack shaft (J) enclosed in a tube. The jack shaft (J) is driven in the usual manner, as a regular split axle, through differential gears and a ring gear (B). The ring gear (B) is driven by a bevel driving pinion (N) which is driven by the drive shaft (S) from transmission. Note the differential housing is fastened to the rear axle.

The brake band (B) is of the external contracting type and is controlled by lever (R), which is connected with the foot brake pedal.

The adjustments on this axle are similar to a "live" split axle, in that the parts necessary to adjust, are the ring gear (B) on differential and bevel drive pinion (N). The adjustment of the differential ring gear (B) is to provide the proper center distance for gears (B and N), which can be done by shifting ring gear with adjustments provided. The adjustment of drive pinion (N) is to provide the proper mesh between the gear B & N. Manufacturers of this type axle are; Russell Mfg. Co., Middletown Conn. Torbensen Co., Cleveland, Ohio also manufacture an internal gear drive axle.

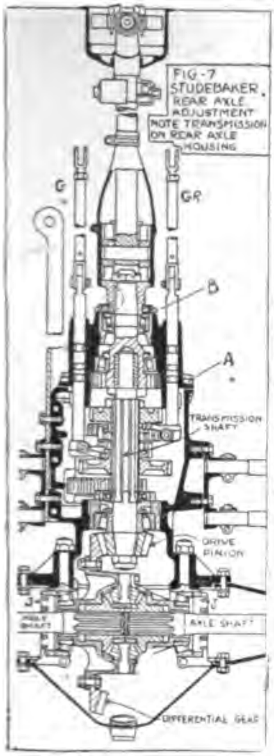


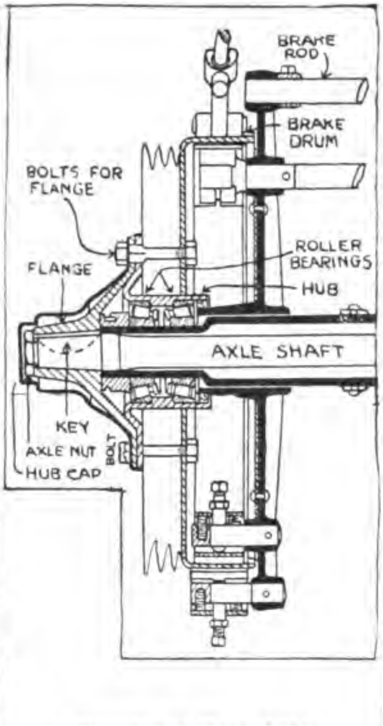


The Russell Type P—1 ton truck internal gear drive axle.

CHART NO. 275—Chalmers and Saxon (Timken Axle) Adjustments. Preventing Oil Leakage from Rear Axle. Internal Gear Drive Axle.

Oil or grease working out through brake drums cause the brakes to slip. This can usually be overcome by placing a felt or leather washer at position shown in fig. 2.





Studebaker Rear Axle.

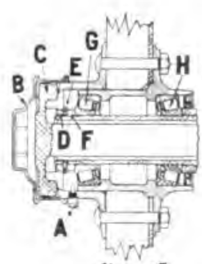


Fig. 47.

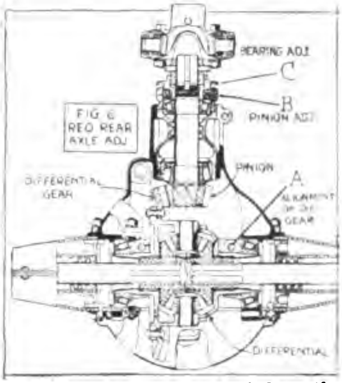


The rear axle is of the full-floating type. In this type the weight of the car is not carried on the axle shafts, but the axle housing extends into the hubs of the rear wheels, and the rear wheels turn on bearings set on this housing, thus relieving the axle shafts absolutely of all weight of the car. Each axle shaft is keyed at its outer end to a driving flange. This flange is bolted to the rear wheel.

By removing the bolts (fig. 6) the flange and the entire axle shaft can be withdrawn, leaving the rear wheel in place and still carrying the load of the car.

Rear wheel bearing adjustment: Jack the wheel clear of the ground. If it indicates play freely when you try to wobble it, the bearing should be adjusted. This can be done as follows:

Take out the axle shaft by removing the bolts at the hub of the rear wheel from the flange. When nuts from the bolts are turned off, the flange and the axle shaft which is attached to it can be withdrawn, exposing bearing adjustment, nut washer, and adjusting lock nut. One of the lugs on the lock-washer will be found bent over, holding the lock nut from turning. Straighten out this lug, and take off adjusting lock nut, also adjusting washer; then turn adjusting nut into the hub until the play between the rear wheel and its bearings disappears. Be careful not to make adjustment so tight as to bind the wheel. When the adjustment is correctly made the wheel should turn freely without wobble. When you have reached this point in the adjustment, replace the adjusting washer, turn on lock nut, and bend one of the lugs on lock-washer over lock nut. Replace the axle shaft and bolt on flange firmly.

Differential: It is advisable at least once a season to clean the differential thoroughly. This can best be done by removing the cover at the rear of the housing and washing out with gasoline. Repack with fresh grease, being careful to replace cover with gasket in perfect condition. The differential can be removed by taking off plate at rear of axle and pulling shafts out far enough to clear it.

Studebaker pinion adjustment on rear axle is made through the nut (B. fig. 7) which adjusts the Timken pinion bearing. To do this, the handhole cover must be removed from the gearcase and the setscrew which holds this nut must be loosened. Great care must be exercised not to adjust this pinion too tight. The rear wheels should be jacked up, the gear lever placed in neutral and the rear cover plate removed.

In aligning the ring or differential, the gear is shifted from one side or the other by turning the adjusting collar (J).

Reo Rear Axle.

Fig. 6—The pinion on the rear axle is adjusted by screwing in the member B; bearing adjustment is accomplished through C and the alignment of the ring gear is shifted from one side to the other by turning the adjusting collars at A. See page 546 for type of axle on the Reo. Note—center illustration shows method of mounting wheel on axle-shaft of Reo.

Removing Cadillac Rear Wheels.

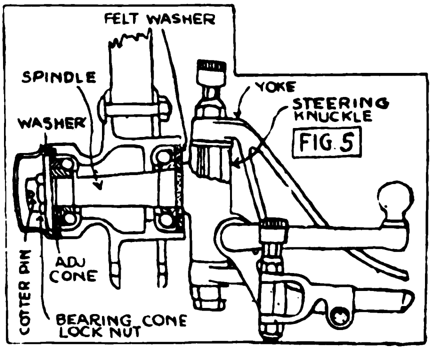
Remove lubricator "A" (fig. 47); remove hub cap "B" by unscrewing it; withdraw axle shaft "C"; jack up the axle so that the wheel will clear the floor; remove the lock nut "D," the washer "E" and the adjusting nut "F"; the wheel can then be taken off.

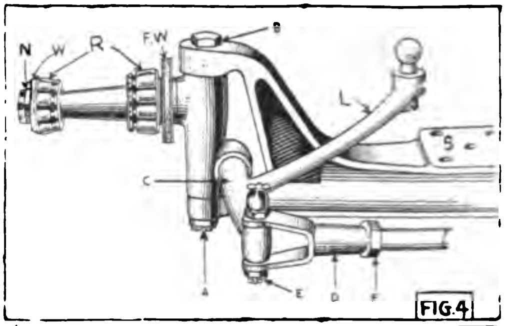
Re-assembling: Before putting the wheel on again see that the bearings "G" and "H" are clean and filled with light grease which is free from dirt and grit. In putting the wheel on again set the adjusting nut "F" very carefully. Place the washer "E" in position, and tighten the lock nut "D."

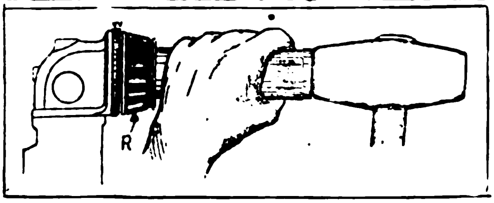
CHART NO. 276—Removing Rear Wheels and Axle Shafts; Studebaker, Cadillac and Reo.

All full-floating axles. Therefore the axle shafts can be removed without removing the wheels or axle housing. Note the two bearings in the wheel hubs and splined inner end of axle shafts. (see page 669 and 83.)

Also note that on the Studebaker (and Overland, chart 268) the transmission is next to the axle housing. On the 1918 Studebaker, it is forward, next to clutch.







Removing and Adjusting Front Wheel.

Jack up the wheel and take off the hub cap. Then draw cotter pin (fig. 5) and unscrew bearing cone lock nut. Note: The lock nut on the right-hand wheel (seated in car) has right-hand threads and to unscrew, turn to the left. The lock nut on the left-hand wheel has left hand threads and to remove, turn to the right. When the lock nuts are removed, the wheel can be pulled off very easily as the cone merely slides on the spindle.

Before replacing the wheel, examine the felt washer. If damaged, replace after prying out retaining washer.

A good method to get the bearing into position, is to slip a short length of pipe over the spindle, against the inner shell of the bearing, and to drive the bearing to its proper place by hammering on the pipe.

Adjusting the ball bearings: In replacing the wheel, press the cone in as far as possible and slide on the retaining washer, then turn the cone until the lug on the washer fits into the recess on the back of the cone to prevent its turning. Tighten up the lock nut until the wheel has no perceptible side play on the spindle, but still revolves very freely; then replace cotter pin and hub cap.

If grease runs out, between hub of front wheel and steering knuckle the cause is due to either too much grease or a defective felt washer.

To see if the front wheel bearings need adjustment, jack up the wheels. Any looseness will show on rocking the wheels sideways.

The best method for adjusting roller bearings (fig. 4), is to turn the bearings up tight, then revolve the wheel a few times by hand; now slack off the nut a little so that by grasping a spoke above the hub and one below, a very slight shake in the wheel is felt, then turn the nut up again slowly until the shake disappears and the wheel revolves freely.

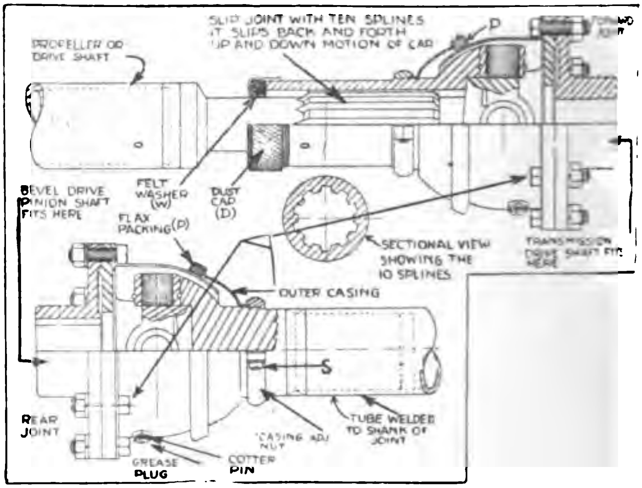


Fig. 7—Spicer Universal Joint.

The Spicer Universal Joint.

The Spicer universal joint is used here for the purpose of an explanation of adjustments and lubrication.

Every 1000 miles remove the grease hole plugs and fill with heavy gear oil or light cup grease. Too much grease will work out; about ⅔ full is correct.

The forward universal joint is provided with a dust cap (D) and felt washer (W) on the rear end of the sleeve into which the end of the propeller shaft slides. This cap should be turned to the right occasionally in order to keep the felt washer tight and prevent the leakage of grease. Both joints have flax packing (P) between the two parts of the pressed steel casings. This packing can be tightened by loosening the bind screw (S) and turning the casing adjusting nut or ring in a right-handed direction.

If the packing in the front universal joint is allowed to leak grease, the joint will not only suffer from lack of lubrication, but the grease will be thrown up onto the emergency brake, rendering the brake inoperative.

Note—Upon examination an "O" will be found on propeller shaft tube upper end; a corresponding "O" will be found on the shank or rear end of the forward universal joint. When propeller shaft and universal joint are assembled these two "O's" must be in line; (as shown in upper drawing fig. 7) otherwise the rear transmission bearing will be subjected to undue strain and excessive wear.

Assembling—When the universal joints have been disassembled again, care should be taken to see that the holes in the flange and the inside casings are matched up in such a way as to bring the oil hole (which is closed by a threaded plug) opposite an open space in the joint, and not opposite one of the lugs, which would prevent the introduction of grease through the hole, the intention being that by removing this plug the user of the car can at any time inject additional oil or grease by the use of an ordinary grease gun.

CHART NO. 277—Front Axles. Universal Joints.—see also text, pages 681 and 43.

Note—In fig. 5, part designated steering knuckle, is also known as the spindle body (see chart 321.)

INSTRUCTION No. 46-B.

ADJUSTING WHEELS, BRAKES AND STEERING: Testing Alignment and Care of Wheels. Camber and "Toe-in" of Front Wheels. Universal Joints. Brake Adjustments and Repairs. Steering Gear Adjustments and Types in General Use.

†Front Wheels.

This subject is covered in chart 277, but additional information will be given below.

Testing Play in Wheels.

Play in the rear or front wheels can be detected by jacking up the car, grasping the rim and working the wheel laterally. (figs. 1 and 4, chart 278.) If the wheel shows the looseness the adjustment nut should be tightened. This nut is located within the hub cap and whatever its shape may be, it is made so that a slight turn makes a considerable change in adjustment. Do not have the wheels too tight but turn the nut until the wobble disappears. In case of ball bearing wheels, it would be well to take out all the balls and examine them for wear. If any signs of wear are found, replace the worn balls at once. The ball races should be carefully cleaned with gasoline and freed from the slightest suspicion of grit. The same attention as regards cleaning should be given bearings.

Taking up play in a front wheel having roller bearings.

If a "click" is heard when turning front wheels with ball bearings—look for a broken or cracked ball—remove it at once, else it will ruin entire bearing.

Adjustment and care of front wheel bearings: Every time a front wheel is removed the bearing cups are removed with it and consequently the bearing must be properly adjusted when the wheel is replaced, if it is to give uninterrupted service.

The best method is to turn the bearing up tight and then revolve the wheel a few times by hand, which overcomes any tendency for back lash.

Then back off the adjusting nut very slightly, so that by grasping two spokes in a perpendicular line, one above and one below the hub you begin to feel a very slight shake in the wheel. If this is more than barely perceptible, it is too much and the adjusting nut should be a little tighter, but not enough to cause any binding of the wheel when rotated. When you have it just right, lock it, and the bearings will give the best of service. (see also chart 277.)

Wheel Lubrication.

Once in every 1,000 miles of running the front and rear wheel bearings should be examined. If one of the rollers should have become damaged it is better to replace all the rollers, to insure that the whole set is of the same dimensions—in which case it is best to order from the factory.

For lubricating wheel bearings use a good, light graphite grease; spread it over and into the bearings and fill the entire hub with it. The bearings should at all times be free from grit, and it is a good precaution to flush them with gasoline whenever you supply fresh lubricant.

Don't fail to see that the felt washer is in place so that grease will not work out between inner part of hub and bearing.

Truing up Wheels.

The wheels may be tested next. This may be done by taking a measurement at a height of about 8 inches from the floor (fig. 2 chart 278). The wheels should next be lined up as shown in chart 279.

**Tightening Hub Caps.

Occasionally hub caps are lost through carelessness in replacing them after lubricant has been applied. While they should be set up snugly, undue force should not be used as the threads of the brass member may become stripped. An excellent plan is to screw the caps up tightly then tap the wrench a light blow with the hammer. Sometimes too much lubricant is used and when tightening the cap, the grease gives one the impression that the cap is snug.

*Universal Joints.

To clean and grease the universal joints in the driving mechanism; first, remove leather boots, if any are provided and clean them with gasoline. In some cars the housing inclosed by the leather boot is a small, cylindrical sleeve held by four set-screws. When these are removed the sleeve may be slipped off the universal joint, leaving this free to be cleaned. All signs of the old oil should be removed and new grease put in. See page 685 for kind of grease to use.

The kind of grease recommended by different car manf'gs. varies, but the oil known as "timing-gear" oil, having a consistency between heavy cylinder oil and vaseline, may be used. Graphite grease is also very good. In some of the more —continued on page 685.

*For a mechanical description see pages 680 and 43. †See also, page 762 "wheels". Note on page 679 and 931 how a rear wheel is fastened to a full floating axle shaft by a flange. Note how a rear wheel on a semi-floating axle is fastened, page 781.

****On wire wheels** it is very necessary that hub cap be drawn very tight else a noise and probable damage will result. See also, page 762.

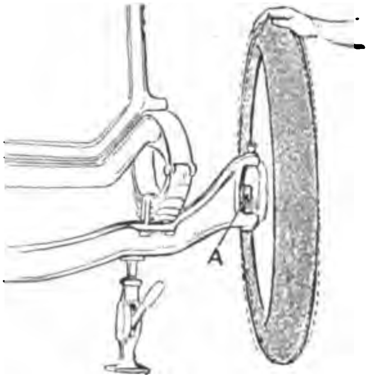

Fig. 1—Testing front wheel bearings: In testing for lost motion in front wheel bearings, a wedge-shaped block or the like should be jammed between the spindle and axle end as shown at A, otherwise lost motion in the spindle or knuckle might be taken for looseness in the wheel bearing. After taking this precaution try to move the wheel as indicated by the dotted lines, and any lost motion in the bearings can be readily felt.

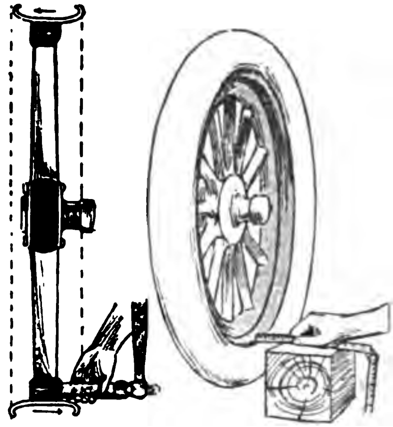

Fig. 2—Truing up a wheel: If a wheel is suspected of being out of true, it may be tested as shown above. With one hand resting on a block to steady it and holding a rule, or the like, close to the wheel rim, the wheel is revolved very slowly; if it is untrue the space between the end of the rule and the wheel rim will vary. If the trouble is simply due to the rim having shifted on the felloe, it may be rectified as indicated at the left in the illustration.

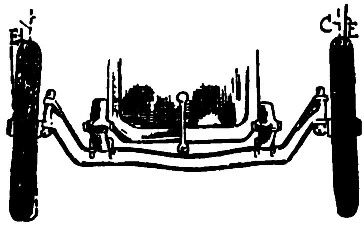

Fig. 3—Sprung axle or spindles: A condition often present in a motor car after a hard summer's use. The wheels should line up as indicated by the lines E rather than as indicated by the dotted lines C. If the wheel wobbles while in operation as indicated by the dotted outline of the right wheel, then the wheel itself is out of true.

Fig. 4—Testing rear wheel bearings: Lost motion in a rear wheel bearing is best tested for by taking hold of the tire with one hand to steady the body, then working the wheel up and down with the other hand, assisted by the knee and lower portion of one leg. When the right hand is placed on the hub, the right leg is often more conveniently used than the left, as shown in the illustration.

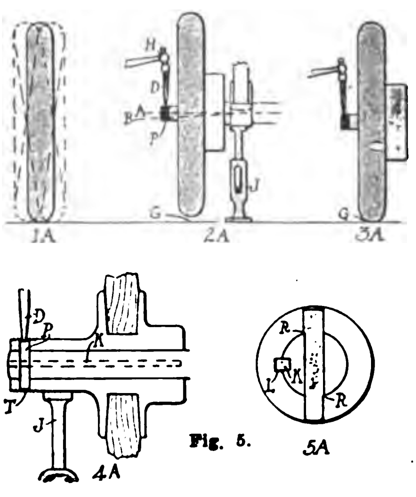

Fig. 5—Rear axle precautions: In removing a rear wheel, an unskilled workman can spring the shaft so that the wheel will afterward wobble as indicated at 1A. This may be done as shown in sketch 2A; with the jack J in the position indicated and the wheel raised from the ground as at G, by using the drift D and hammer H to remove the pin P, a few sharp blows are sufficient to bend the axle as indicated by the dotted lines A and B. This can be avoided if the wheel were allowed to rest on the ground G as in sketch 3A; or by placing the jack J under the hub as shown in sketch 4A. When the key K is loose, as indicated by the dotted lines L in sketch 5A, grooves R may have been worn into the pin which prevent it from being easily removed.

CHART NO. 278—Testing Wheel Bearings. Truing up Wheels.

Alignment of Wheels.

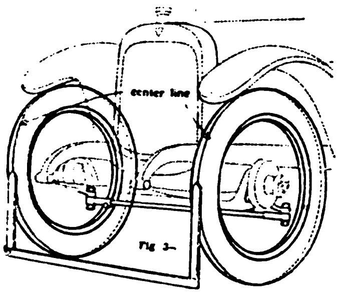
This subject is of more importance than one would imagine. For instance, if the wheels are not properly "lined up" there will be wear on the tire and steering will not be easy. If a car has been subjected to severe jolting or has struck a curb, the wheels may have been thrown out of alignment or the back or front axle moved sideways.

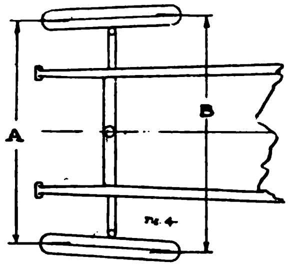
Lining up Springs with the Axle.

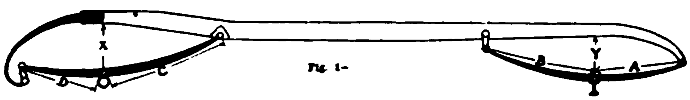
Measure distances (fig. 1) from horneye of spring to center of axle as shown at A, B, C and D also X and Y. The distances should be the same on each side of car. Measure with a stiff straight edge of some sort, not a tape line.

Lining up Front and Rear Wheels.

Measure the distance from center to center of hub as at E (fig. 2.) This should be the same on each side. If not, loosen spring clips and move front axle slightly. It will be possible to move either about ¼ inch on most cars.







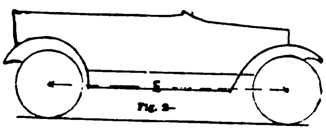
"Camber" of Front Wheels.

Is for the purpose of making steering easier; because wheels have a tendency to spread apart at bottom and come together at the top when speeding.

Camber means that the wheels are closer together at the bottom than at the top and the slant is usually, not more than 2 degrees or about 2⅝" for 34" wheels.

This is usually done at the factory by tilting the steering knuckle, if not, then it can be done by bending the front axle between the spring seat and the steering knuckle yoke. It is best to bend cold if possible, if heated, don't heat quite red.

The track should then be the same as the rear wheels.



The idea of cambering is to make the center line of spindle bolt coincide as near as it is practical, to center of contact of tire with the ground—see page 774.

True up Front Wheels.

Before proceeding further this is necessary. This can be done by following plan in fig. 2, chart 278. If wheels are wobbly it may be due to loose bearings or sprung rim.

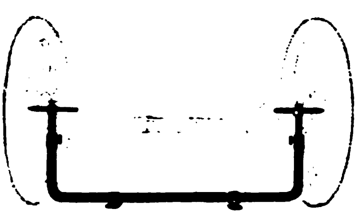
"Toe-in" of Front Wheels.

*This means that the distance from center to center of tire as at A (fig. 4) should be from ¼ to ⅜ inches less in front of wheel than at rear as at B—when measured in front of tires about half way up even with the hubs. Don't compare "toe-in" with "camber," as camber means wheels set in at the bottom.

The above measurements are correct for comparatively new cars and should be increased somewhat as the steering knuckles become loosened through wear.

The "toe-in" can be adjusted by adjusting the length of the steering knuckle tie rod, from one steering knuckle to the other. This adjustment should be made with wheels on the ground. The idea of "toe-in" is necessary because when running, the wheels have a tendency to "toe-out" when car is in motion. Unless properly toed-in, if too much or not enough, the treads of the tires will grind.

The front and rear wheels should track, if not, the fault can be detected by the front and rear wheels leaving two distinct tracks behind when running on a wet road.



The illustration shows an auto running gear aligner, which has a graduated scale and will make exact measurements on the felloe of wheel, front and rear (instead of center to center of tire) at the exact horizontal center of the wheel. Mfg'd by Mechanical Utilities Corpn., 5 North LaSalle St., Chicago.

To Check the "Toe-in."

One method is shown in fig. 3. Jack up front axle. Make a center line on each tire as wheels revolve. Then measure the distance from one line to the other. A straight stick with uprights can be used as shown in fig. 3. The measurement should be made at points about where the tops of the upright are shown in the illustration and this distance should be about ¼ to ⅜ inch less in front than rear, as at A, fig. 4. Another method (and one that is more accurate) is shown in the illustration to the left.

Keep Spring Clips Tight.

It is well to notice the spring clips occasionally, especially when car is new. In fact it is a good idea to tighten bolts holding spring clips about every 500 miles of running. A loose spring clip will often cause a mis-alignment.

Why Tires Wear Unevenly.

Quite often, when front tire has a worn place around tread, it is due to mis-alignment. Why a right rear tire wears faster than others is due to the crown of the road being oval, also because most of the driving is done on the right side, the weight is thrown more on that side.

Dodge front wheels should "toe-in" ⅜", measured on felloe of wheels level with hub.

CHART 279—Alignment of Wheels. Excessive tire wear is often caused by improper alignment.

*The height from ground where measurement is taken should be at the horizontal center of the wheel, or a height which would be the center of the hub.

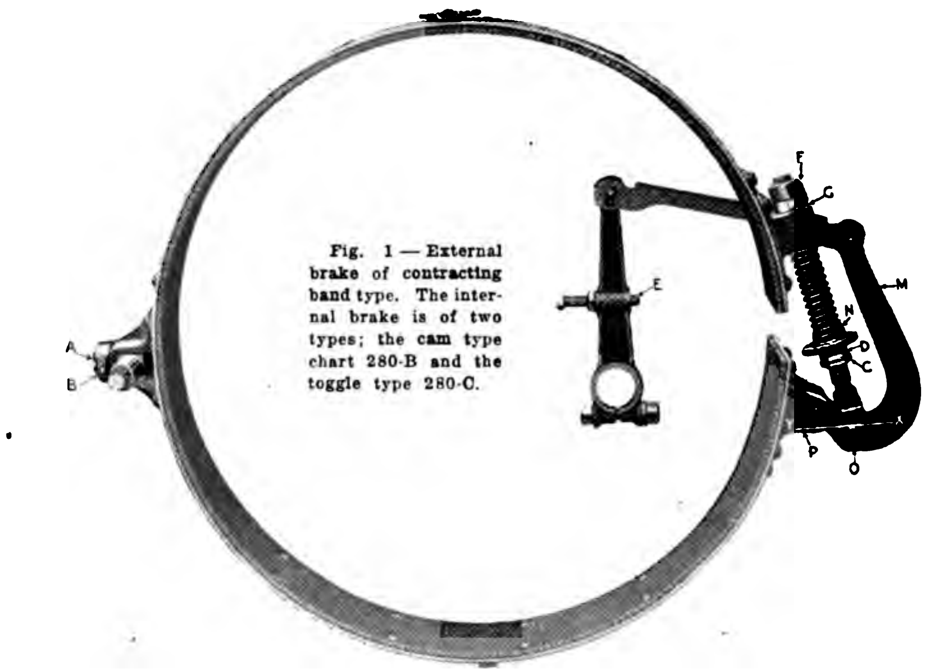


Fig. 1 — External brake of contracting band type. The internal brake is of two types; the cam type chart 280-B and the toggle type 280-C.

Brake Troubles—the Cause.

When brakes will not hold it doesn't necessarily mean that the bands need adjusting. Oil or grease may cover the friction surfaces. Before jumping at the conclusion that the bands need new linings take off the wheels and examine the asbestos. If lubricant has saturated the linings, wash off the grease with gasoline or kerosene.

As brake linings wear it becomes desirable to adjust the brakes in order to get that perfect action so necessary to safety and satisfactory service.

Adjusting brake rods: Failure of the brakes to hold as securely as is desirable—note this fact carefully—may be due to insufficient **forward** travel of the rods connecting the brakes with the foot pedal or hand lever.

Dragging may be due to insufficient backward travel. **The remedy** for either of these troubles should first be sought by lengthening or shortening the rods. Until after this is done no adjustments should be made in the brakes themselves.

External Brake Adjustments.

First of all put jacks under the rear axle, being careful to have them press up against **the housing proper (or on some Timken axles, against the pads made for this purpose), but never against the truss rods. Raise both rear wheels off the ground.**

Next, put all the brakes on both sides of **the car in a complete "off" position.**

Before making any adjustments of the brake make sure that stop-screw (E) is so adjusted against the housing that the clearance between lever (M) and the support indicated by circle (N) is about $\frac{1}{16}$th inch when the brake is in "off" position. If no stop-screw (E) is used, accomplish the same purpose by lengthening or shortening the brake rod.

It is very important to make the following adjustments in such manner and degree that when completed and the brake is applied full force, the imaginary line X—Y running over pin (O) and under pin (P) will stand about as shown in the illustration (figure 1). This is necessary to insure proper toggle action by lever (M).

Begin at the rear of the brake by removing cotter-pin (B—fig. 1) and turning the adjusting screw (A) until the clearance between the drum and the brake band lining at this point is the least possible without the drum touching when it revolves. Try $\frac{1}{64}$th inch clearance to start and increase it if necessary only enough to allow all parts of the drum to clear as it revolves. Then replace cotter-pin (B).

We are now ready to adjust the lower half of the brake band. Loosen jam-nut (C) and turn stop-nut (D) up or down on the stem until all parts of the drum just clear the brake band lining say about $\frac{1}{64}$th of an inch. When this proper clearance has been obtained turn jam-nut (C) tightly against stop-nut (D) to lock it.

Now for the upper half of the brake band. Get the same bare clearance all around the drum by turning nut (F) being sure that it is always turned to a place where the groove (G) (in its under surface) fully engages the rib on the top of the fitting, thus automatically locking the adjustment.

CHART NO. 280—Adjusting Brakes—Timken as an example. External contracting band type.

—continued from page 681.

inaccessible universal joints it will be safer for the amateur to merely renew the grease without attempting to disassemble the housing. (see page 580.)

Should a knock or rattle develop, it is a case of disassembling and rebushing the joint. Quite often it pays to order a new part rather than repair it.

*Brake Adjustment, Care and Repair.

The brake mechanism of a car is divided into three general classifications as follows: —(1) external contracting band; (2) internal expanding band; (3) internal expanding shoe.

The operation of the brake mechanism on or in the brake drums, is divided into 4 classifications; (1) external contracting band by a fulcrum arrangement to draw the band tight around the drum; (2) internal expanding band, expanded by a "cam" arrangement as per chart 280-A; (3) internal expanding band, expanded by a "toggle" joint arrangement as per chart 280-B; (4) internal expanding shoe, (usually of metal, similar to fig. 2, below) operated by a "cam" arrangement.

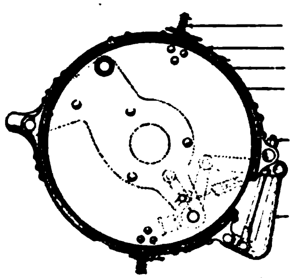

Fig. 1—Names of parts of the external contracting band brakes (Overland).

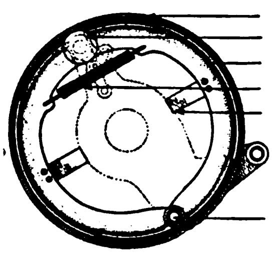

Fig. 2—Names of the parts of the internal expanding shoe (metal) brake, hinged type. The shoe on this brake is lined with fabric, but sometimes we find this shoe without lining and made of bronze.

The external brake is operated, usually by a foot pedal and is called the **foot brake.**

The internal brake is operated usually by a hand lever and is called the **hand brake**—formerly known as the emergency brake—see pages 28 to 30. Sometimes a brake pulley is mounted on the external part of the transmission shaft and connects with the hand lever, it is then called the **transmission brake**, but is usually operated by the hand lever, therefore it would also be termed the hand brake.

The band brake is the most popular—for both internal and external use.

Where metal to metal brakes are used a constant and extravagant supply of oil is required to prevent excessive wear. The inconvenience and uncertainly of lubrication together with the cost of renewing the expensive brake shoes, rendered this type of brake unsatisfactory.

The ideal brake lining then is one in which the co-efficient of friction is maximum and the deterioration due to heat is minimum. A special treated asbestos is the only material today of which such a brake lining can be made. Asbestos is a fibrous mineral; a natural rock, heatproof and will stand considerable usage without excessive wear.

Care of Brakes.

As the safety of a car depends on its brakes, they must be kept in the best possible condition. They should bind tightly when pressure is applied to them, and be free and clear when the pedal or lever is released. A brake band or shoe that binds when the pressure is released, produces friction and makes the car hard running.

Slipping of brakes is caused by either poor adjustment, *oil between the surface, or worn linings. The first may be cured by readjustment. In the second case, wash out the oil with a little gasoline and then stop the leakage of grease out the rear axle.

Slipping caused by worn linings may be remedied to some extent by taking up the adjustment, but if too much worn for this they must be replaced. Replacing the worn lining is not difficult, as the leather or fibre is held to the steel band by copper rivets. Replace with others to hold the new lining.

Because the application of the brake generates heat, leather linings will be burned if kept in contact too long. For this reason, the brakes are usually lined with fabric, called raybestos or multibestos.

If when applying the brakes, the car has a tendency to skid to one side, this indicates that one wheel is free and other dragging. Brakes are not equalized in adjustment. Therefore the brake resistance should be equalized.

The operator can save considerable on his brakes if applied gradually. For instance, if a stop is to be made, instead of dashing up to the stop and applying the brakes with full force suddenly, simply coast to the stop and gradually apply the brakes or not at all. This of course, requires practice.

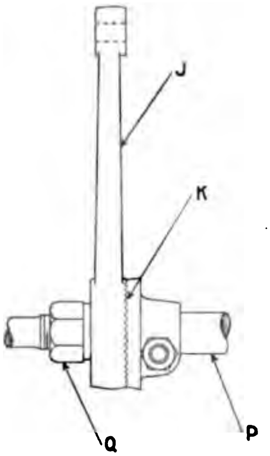
If a brake squeaks it is dirty and needs cleaning by removing and cleaning with a stiff brush and gasoline. The dirt clogs the pores in the surface of the lining and glazes it over, which causes the squeak.

Lubrication of brakes: While asbestos lining requires practically no lubrication on account of its high resistance to heat, it is advisable to apply a few drops of thin oil to the brake shoes or bands occasionally, or about every 2000 miles. This maintains a smooth surface on the brake drum.

See that hinges, cams, toggles and lever bearing are kept well supplied with oil. If an external contracting brake should chatter, apply three or four drops of oil to the friction surfaces. **Cleaning brakes**—see page 688.

—continued on page 691.

*A common brake trouble is slipping—due generally to oil or grease working out of the rear axle. Therefore the first and most important point is to stop this leak by putting in a washer—see page 678.



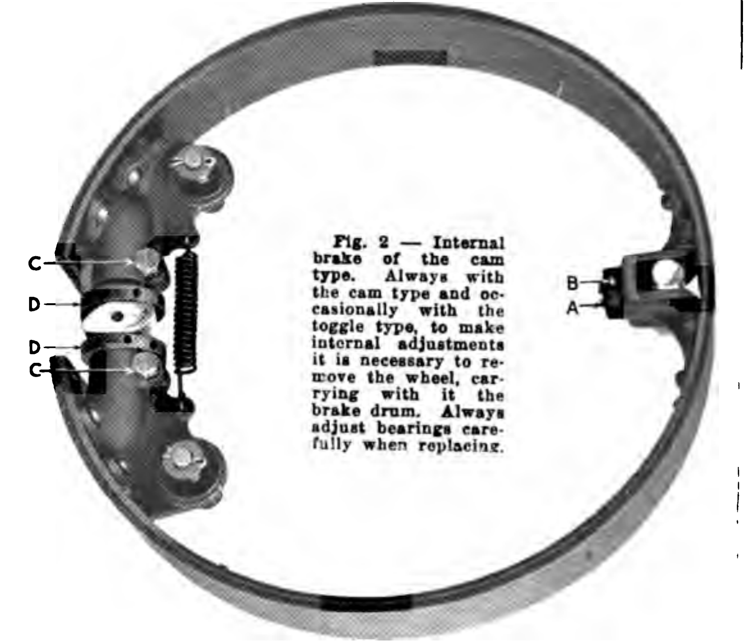


Fig. 2 — Internal brake of the cam type. Always with the cam type and occasionally with the toggle type, to make internal adjustments it is necessary to remove the wheel, carrying with it the brake drum. Always adjust bearings carefully when replacing.

Adjusting Timken Cam Type Brake—(internal).

Slight wear of the brake band lining ordinarily can be taken up without getting into the brake proper. This is done by loosening nut (Q) and moving lever (J) forward one notch in ratchet (K), then tighten nut (Q)—perhaps two notches forward may be required.

For more band lining wear—put jacks under rear axle, being careful to have them press up against the housing proper (or, on some Timken axles, against the pads made for the purpose,) but never against the truss rods. Raise both rear wheels off the ground.

Next; put all the brakes on both sides of the car in a complete "off" position.

If the adjustment is merely to take up for wear of the brake lining in service it is only necessary to (1) remove the wheel which also removes the brake drum; (2) remove cotter-pin (B), give adjusting screw (A) two turns to the right (i. e., in a clockwise direction) and replace pin (B); (3) loosen screws (CC), give cam plates (DD)) one-half turn outward (i. e., to the left or contra-clockwise) and tighten screws (CC). Put the wheel back on and try the brake in "off" position for a bare yet sure clearance so it will not drag. Try it in the "on" position for holding power.

If greater clearance is required—remove the wheel and partially reverse the adjustments detailed in the preceding paragraph.

If still more holding power is desired and there is some clearance yet to spare in the "off" position—remove the wheel and repeat the adjustments to a partial extent.

When more elaborate adjustments are required, than are required when merely compensating for wear of the lining—it is best to use a dummy or skeleton drum, that is, one with parts of its outer flat surface cut away to give ready access to the interior.

Garage men who have enough of such work to warrant it usually have, or can obtain from the Timken Co., Detroit, Michigan, a dummy drum. It is a great time saver. But by removing and replacing the wheel a few times the same result can be obtained by "cut and try" and the following directions based on the possession of such drum will be a true guide to that method as well:

Adjustment when using dummy drum: With both rear wheels off the ground and all the brakes on both sides of the car in a complete "off" position remove the wheel and insert the dummy drum in the place occupied by the drum on the wheel just removed.

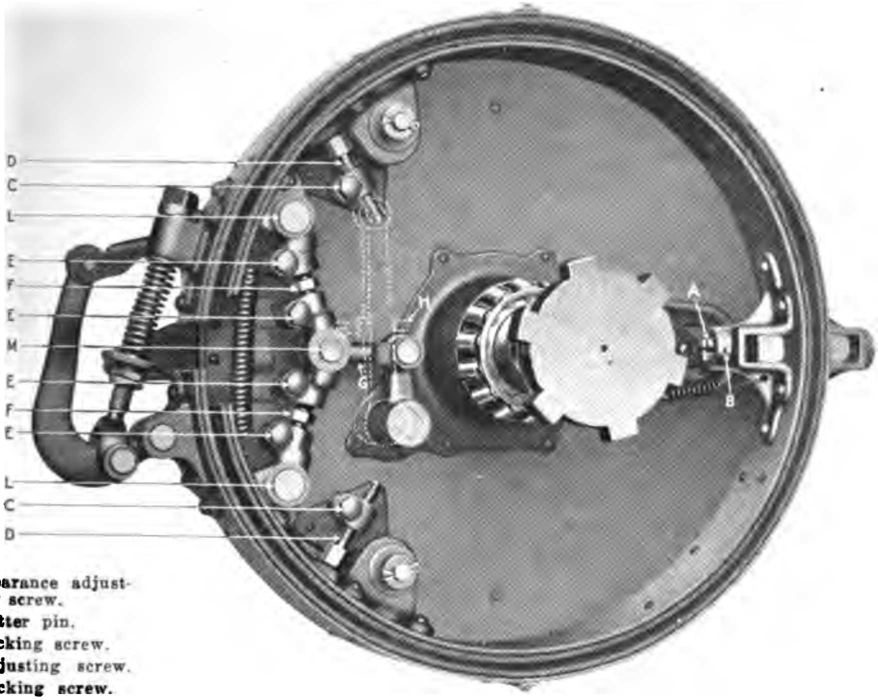
Begin at the rear of the brake by removing cotter-pin (B). Turn screw (A) in or out until the clearance between the drum and the brake band lining at this point is the least possible without the drum touching when it revolves. Try 1/64th inch clearance to start and increase it if necessary only enough to allow all parts of the drum to clear as it revolves. Then replace cotter-pin (B).

Next adjust both upper and lower halves of the brake band by loosening screws (C C) and turning plates (D D) in or out until all parts of the brake band lining just clear the drum by about 1/64th of an inch. Then tighten screws (C C).

To determine whether the brake band lining bears against the drum all around set the brakes, not too tight, and feel for any openings between the drum and the brake band lining with a thin piece of metal. Do this from the inner side of the drum. After completing these adjustments of the brake band turn cam-shaft (P) with your hands (top of shaft forward) until the brake band lining barely clears the drum, allowing the wheel to turn freely. With the driver's foot pedal or hand operating lever in "off" position adjust the length of the brake-rod so that lever (J) will stand in a nearly vertical position (leaning slightly backward).

Then tighten nut (Q). In replacing the wheel be sure to properly adjust the Timken bearings.

HART NO. 280-A—Adjusting Timken Brakes—Continued — Internal expanding band — "Cam" ype.



A—Clearance adjusting screw.
B—Cotter pin.
C—Locking screw.
D—Adjusting screw.
E—Locking screw.
F—Toggle adjusting screw.
G—Connecting link.
H—Stop screw.
L—Fulcrum pin.
M—Toggle pin.

Fig. 3—Timken internal expanding band operated by a "toggle" mechanism; this type is equipped with a triangular covered opening in the flat part outer surface of drum—through which adjustments can be made without removing wheel. In extreme cases—a dummy brake drum can be used, as explained in chart 280-A, which of course saves time. These directions explain the adjustments with or without the use of the dummy.

Adjusting the Timken "Toggle" Type Brake—(Internal).

First of all put jacks under the rear axle, being careful to have them press up against the housing proper (or, on some Timken axles, against the pads made for this purpose), but never against the truss rods. Raise both rear wheels off the ground.

Next, put all the brakes on both sides of the car in a complete "off" position.

Begin at the rear by removing cotter-pin "B," turn screw (A) in or out until the clearance between the drum and the brake band lining at this point is the least possible without the drum touching when it revolves. Try 1/64th inch and increase it if necessary only enough to allow all parts of the drum to clear as it revolves. Then replace cotter-pin (B).

Next adjust both upper and lower halves of the brake band by loosening (CC) and turning screws (DD) in or out until all parts of the brakeband lining just clear the drum by about 1/64th of an inch. Then tighten screws (CC) to lock the adjustment.

Next adjust the toggle so that a straight line touching the rear of the heads of pins (LL) will just touch the front of pin M. Loosen screws (EEEE) and turn screws (FF) until the forward edge of pin (M) is barely visible under any short, thin straight-edge laid against the rear of the head of pins (LL.) When this is true tighten screws (EEEE).

Timken tapered cone type roller bearing. Used for wheel bearings, axle bearings and different parts of the car, see pages 673 and 674 of Timken axles—showing use in connection with axle parts. The part to the left is a case hardened steel race in which the roller friction is applied. Note also the inner race. (see page 36 for other types.)

Adjusting a Timken Bearing.

To adjust Timken bearing—turn the bearing up tight, and revolve the wheel a few times by hand, which overcomes any tendency to back-lash. Then back off the adjusting nut very slightly, so that grasping the two spokes in a perpendicular line—one above and one below the hub—you begin to feel a very slight shake in the wheel. If this is more than barely perceptible, it is too much, and the adjusting-nut should be a little tighter. When you have it just right, lock it, and the bearings will give the best of service.

CHART NO. 280-B—Adjusting Timken Brakes—Continued—Internal expanding band—"**Toggle**" type. **Timken Roller Bearing Adjustment.**

Overhauling Brakes.

There are three things which must be particularly noticed in taking care of brakes and putting them in condition:

Fig. 1—Removing grease from under fabric.

(1) There must be no grease on the shoes; (2) The **fabric** must be in the best of condition; (3) The brake linkage **must** apply the brakes when pedal is depressed.

The grease: The grease which penterates to the brake lining usually works its way from the differential and can be stopped by renewing the washer in wheel hub.

To remove grease, first remove wheel, then inspect brake lining and see if it will come under head of No. 1 or No. 2 in the list above.

If a coating of grease is over the surface of the fabric there will be two methods of procedure. The first method for removing grease is by the application of gasoline. This removes the grease from the outer surface very well but not from below the surface of the fabric. A blow pipe torch can be used in this instance, which can be gently applied as shown in fig. 1, being careful to not char the fabric.

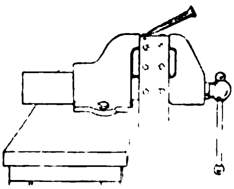


Fig. 2—Method of cutting rivets on worn band.

After the heat has been directed against the surface of the brake for a short length of time it will be noted that the grease will literally fry out of the fabric, leaving it upon the surface in the form of a black carbonaceous deposit. In this state it is readily removed by a cloth steeped in gasoline. The surface of the brake will now be in good condition if the lining has not been worn out.

If brake lining is badly worn down so far that fabric lining is too thin to be of service, then a new brake lining must be applied.

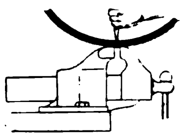

Fig. 3—Punch the cut rivets out.

Relining Band Brakes.

To reline the external brake: First, jack up rear wheels. Disconnect the levers, etc. from the brake bands and remove **wheels** and bands, being careful to keep all parts separate so they can be replaced with ease.

Second; wash all parts in gasoline, or kerosene to remove grease and dirt.

Third, remove old brake lining, by placing band in a vise and cut the rivets with a chisel, fig. 2, then open up the bench vise about ½ inch, setting the bands so that the old rivets come over the opening one at a time, drive them out with a nail set, fig. 3. As the heads will most likely be worn off, it is easier to drive them from the lining side through to the band side. The old lining can then be easily removed from band.

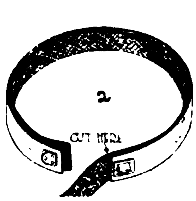

Fig. 4—Method of determining length.

Measuring: It is best to secure the lining from the automobile dealer or manufacturer ready to apply, but if this is not possible, then proceed as follows: Lay a tape measure around the outside of the external brake band allowing for an over-lapping of about ½ inch at the edges of the band opening. Or place the lining inside of the band per fig. 4, or measure the length from the old band.

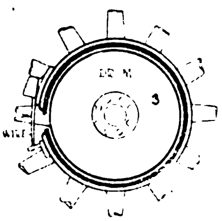

Fig. 5—Method for marking lining for hole.

In marking the lining for the holes, lay the wheel on a bench or the floor, hub side down, and putting the lining and band in place on the drum, as shown in fig. 5, wire the band so as to hold it in place correctly. With a pencil, using the holes in the band as a template, mark the lining. The holes can then be made by using a harness leather punch, or hand punch. **It is important that the holes be in the correct position** so that there is no slack in lining to form a hump. If too short it will lay uneven in the band.

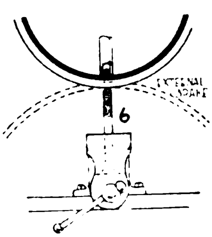

Fig. 6—Placing rivets.

Securing band to lining. With the aid of a few small bolts and nuts placed at intervals, secure the lining to the band in its proper position. **The next step is to countersink the holes so the rivet heads will be below the surface of the lining.** To do this properly one should use a countersinking tool made for such purpose, as shown in fig. 8, page 690, one can get good results however, with a wood screw countersink tool and a brace. If the latter is used it should be sharp or the lining will tear. Do not countersink too deep, just enough to permit rivet heads to be below lining surface.

—continued on page 689.

CHART NO. 280C—Overhauling Brakes. Relining Brakes. See page 615 for size of Brake Lining for 1919 Cars.

—continued from page 688.

To place rivets, see fig. 6, this shows a way of using a bolt held in a vise with the head of the bolt resting on the arm of the vise to give a solid foundation.

The illustration shows internal brake curved up and external brake curved down. The rivet head goes next to fabric and riveting always done on the band side.

Insert a rivet through the lining and band as in fig. 6, the head of the rivet resting on the bolt, draw the rivet snug with a rivet set, or short piece of small gas pipe. Two or three blows with a hammer will be enough to draw the rivet head and lining tight and in place, too much pounding is very bad as well as unnecessary as it will tend to draw the rivet deeper in the lining and perhaps weaken it to the point of breaking through. Not over 1/16 in. should protrude through band.

To rivet: Still holding the band in the same position, the projecting or the hollow end of the rivet is peined down with the ball pein of the hammer till a good head is formed and the rivet draws tight.

When riveting the external brake, start at one end and work to the other, being sure the lining fits tight, otherwise there will be humps. A method employed by many repairmen to get band tight is shown in fig. 7, page 690.

The riveting is started at the center on the internal brake, working out from the center on both sides and stretching as the work proceeds. Any surplus lining which extends beyong the bands after the riveting is completed is cut off flush.

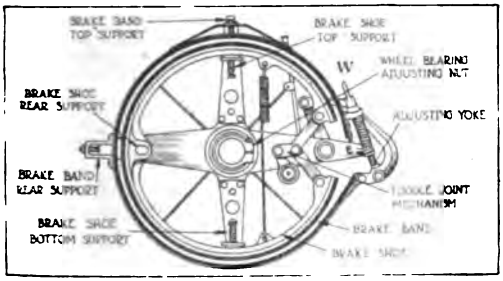
The rivets used are of soft brass with cupped head and hollow end and can be supplied by accessory houses.

Do not remove the bolts that were used as temporary holding until the holes not occupied by bolts have been filled with rivets. This will complete the foot brake and the same methods are used in relining the internal or hand brake.

If brake is of the metal to metal type then it is a matter of adjustment.

*Relining Brakes on Dodge.

Operation: (1) Jack up rear wheels; (2) remove wheel flanges; (3) remove wheel bearing adj. nut; (4) remove wheel and brake band; (5) wash brake bands; (6) remove old brake lining; (7) rivet new lining bands; (8) replace brake bands; (9) put wheel on; (10) replace and adjust wheel bearing adj. nut; (11) replace wheel flanges; (13) adjust brakes.



Adjusting Dodge Brakes.

External brake is connected with foot brake pedal: Adjust the hex check-nuts on the lower part of the adjusting yoke, as well as the wing nut (W) at the top, in order that the band may be taken up as much at the bottom as the top.

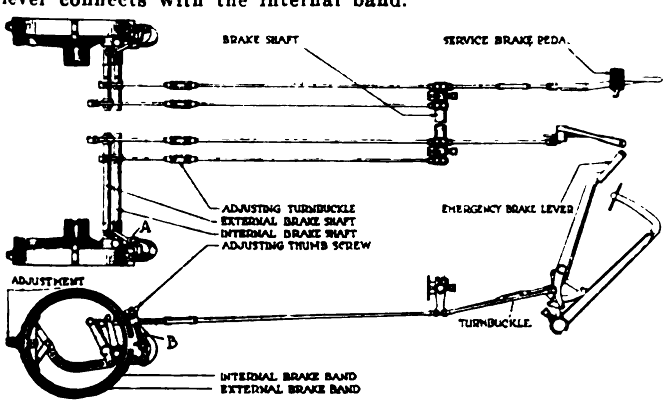
See that the "brake-supports" are adjusted so that the brake band takes hold evenly all the way around and does not drag when released.

To adjust the internal brakes, take up on front end of pull rod.

Material required for a Dodge brake relining job; 88 in. lining 2¼x3/16 inch for external brakes; 71 in. lining 2x3/16 inch for two internal brakes; 12 steel cotter pins 3/32x¾ inch; 80 brass rivets 5/8 in. long, ⅛ in. di., ¼ in. head.

Adjusting Brakes on Buick Light Six.

The internal and external brakes are steel bands lined with friction fabric. The foot brake pedal connects with the external contracting band and the hand, or emergency brake lever connects with the internal band.



Adjustment of the foot or service brake: (1), adjust rear support screw leaving 1/16 in. clearance; (2), adjust bottom of band to drum to 1/16 in. clearance; (3), adjust top clearance same. A "thumb-screw" takes up top half of band and a "hex-nut" on lower part of it, takes up the lower half of band.

Adjustment of the hand or emergency brake: The adjustment can be made by shortening the rods with the turnbuckles.

CHART NO. 280D—Relining Band Brakes. Dodge Brake. Buick Light Six Brake Adjustment.

*See page 932 for Dodge Rear Axle.

Fig. 21 — To force a one-piece clutch lining on a cone clutch, insert a rat-tail file in a bit brace. Force the lining on as far as it will go with the file, which should be a coarse one, and by turning the bit brace the file will roll the lining into place.

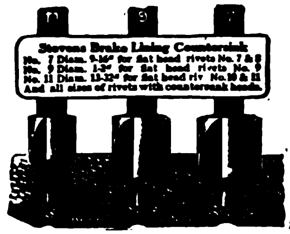


Fig. 8.

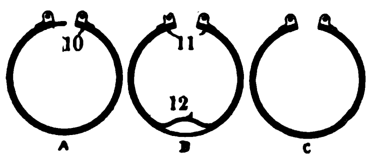
Fig. 8—A brake lining countersink for flat head rivets 9/16, 1/2, 13/32 inch. This device will countersink holes in any style of brake or clutch lining. Shank is 5/16 inch di. and works on a hand or power drill. (Stevens Co., 375 Brodaway. N. Y.)

Fig. 7—When relining brakes some repairmen use the following method to get band tight. Rivet first at 10, then at 11. This leaves a slack which is drawn up when riveted at 12. This forces lining tight against band all way 'round if proper length.



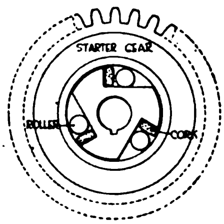


Fig. 9.

Fig. 9—Starting motor clutch on Hupmobile 32, if worn so that it slips can be remedied by inserting cork strips 1/8-in. in rear end of clutch cyl. recess.

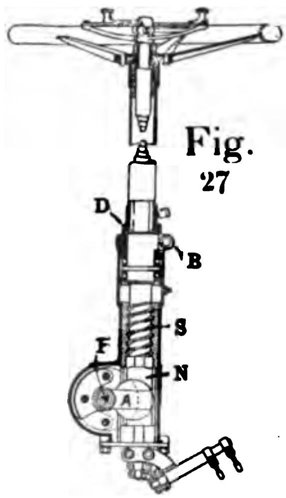

Fig. 27

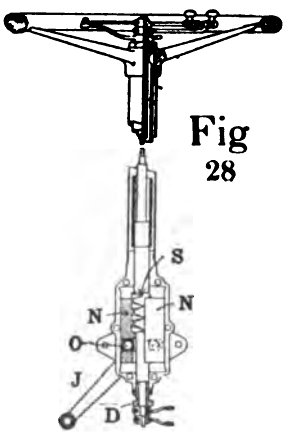

Fig 28

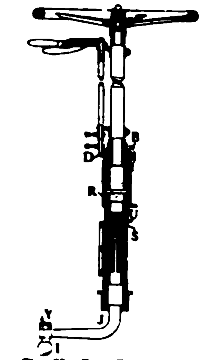

Fig. 60. Ross Cross Type Steering Device For Trucks.

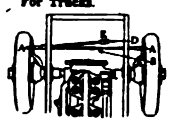

Fig. 61. Cross Steering With All Connections in Front of Axle.

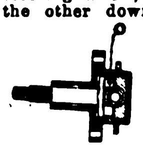
Fig. 28—Lavine steering device—Type; screw and half-nuts. Action; nuts (N) are divided and operate on right and left hand threads cut in a worm or double threaded screw S. When turning steering wheel, one nut moves up, the other down, causing (O) to operate arm J.



Adjustment is by nut (D) at bottom. Lubrication; grease.

Fig 27. Ross "fore and aft" steering device for trucks. Type; screw and nut. Action; movement of steering wheel turns screw (S). This causes nut (N) to travel up or down which moves A, F and J. Adjustment; loosen clamp bolt B and tighten down D.

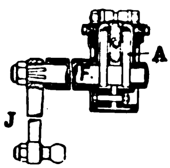


Fig. 60 — Ross "cross-type" steering device for trucks. Note ball I on arm J fits into end of drag link D at K (fig. 61). Type; differential screw. Action; arm J caused to turn by a differential action of one screw of fine pitch operating into another screw of coarse pitch. Adjustment; loosen B and tighten D. Lubrication; oil injected at top.

CHART NO. 280E—Miscellaneous Repairs. Steering Devices.

Adjusting Brakes.

There are two types of brakes in general use, the internal expanding brake and the external contracting brake—see page 685.

Most of the brakes now in use are lined with brake lining or a kind of asbestos fabric.

Before starting to adjust the brakes, jack up the wheels and see if the bearings are tight, if loose, brakes will be out of line and bearings should be taken up.

Test brakes to see if band is badly worn. If so, a new lining will be needed. Also see if the lining has worn down to such an extent that the rivets have cut the brake drum—if so, then the wheel must be removed and the brake drum smoothed down with emery cloth, or in bad cases turned true and even on a lathe. If band is not entirely worn down then the brake band can be adjusted for clearance.

Clearance adjustment of the external brakes is very important. If the band touches the brakes at different points of its circumference then the brake will drag at that point, which of course, consumes extra power and wear on the lining. The purpose of adjusting this clearance is to relieve the drag or to take up on an excess of clearance due to wear of lining.

The proper clearance on most brakes is about 1/64 to 1/16 inch all 'round. Usually this clearance can be taken up by loosening the lock nut O, page 684 and tightening up the nut (D). This ordinarily is sufficient. If however, the clearance can be more or less at the rear, then the clearance can be adjusted at A and B. The top half of brake can be adjusted by screw (F). However, the top half of brake is always given slightly more clearance than the bottom because the drum revolving in a right hand direction has a tendency to draw the top half of band to the drum.

If the brake drags at any other point in its circumference, then a large screw driver can be wedged between brake band and drum and by slightly hammering on each side of the band the clearance can be gained, together with adjustment of the adjustment screws and nuts.

Many repairmen adjust brakes with wheels on the ground and after making adjustment, car is moved backward and forward to see if band drags and be sure that both brakes are adjusted equally.

To adjust the internal brake, see pages 686 and 687. Ordinarily the adjustment is made by taking up on the pull rods.

Don't forget to oil all the levers and joints connected to the brake after making adjustment.

The foot brake requires more adjustment because it is used most. **The hand brake is mostly** used for locking the wheels when standing and at intervals in conjunction with foot brake on steep hills, therefore it requires less attention.

Brake Pedal Adjustment.

Sit in the driver's seat and test the pedal to determine if it is in the correct position for proper braking tension when brake pedal is applied. If not, it should be adjusted by movement of turnbuckle, per page 689. The lever (M), page 684 should be in toward the band in order to allow for full leverage.

**Brake Lining—Size and Price.

There are several good brands of brake lining on the market. For instance Multibestos, Raybestos, etc.

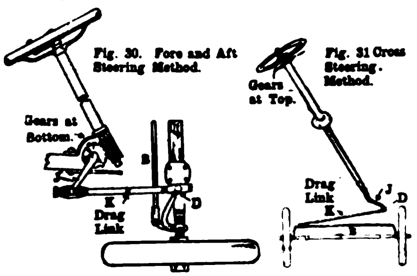
The sizes are usually measured in thickness and width and sold by the length, per foot.

The thicknesses run from 1/4, 5/32, 3/16, 1/4 and 5/16 inch. The **widths** run from 1, 1 1/4, 1 1/2, 1 3/4 on up to 6 inches wide. The **price** varies from 33c per foot to \$3.60 per foot. The Ford uses 1 1/2x5/16" and sells for 40c per foot.

**Steering Gears.

There are two methods in general use: (1) The "fore and aft" method. (2) The "cross method."

The "fore and aft" method is shown in fig. 30. With this method the reduction gearing is usually in the bottom of the steering device and the connecting rod (B) is usually behind front axle.



The "cross steering" method, is shown in fig. 31. With this method the reduction gearing can be either at the top or bottom and the connecting rod (B) can be either in front or behind the front axle.

The Ford and model "Four" Overland and Chevrolet "Four Ninety," employ planetary gears for reduction. The Ford gears are at the top of the steering column (fig. 31), and on the Overland model "Four" and Chevrolet, at the bottom (fig. 37, page 693).

Types of Steering Gears.

There are a number of methods for reducing the ratio of movement of the steering column shaft to that of the arm (J).

(1) **Pinion and sector type,** see fig. 20 (illustrations to the right), and fig. 6, page 693.

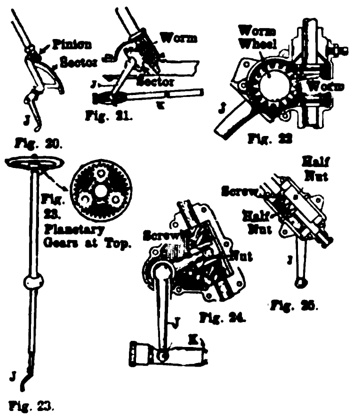
(2) **Worm and sector type,** fig. 21. Note teeth are only on a section of the sector.

(3) **Worm and worm wheel type,** fig. 22.

(4) **Planetary type.** Note the gears are at top of the device on the Ford, fig. 23, and at the bottom on the Overland model "Four" and Chevrolet, fig. 37, page 693.

(5) **Screw and nut type,** fig. 24. Movement of nut is up or down which moves arm J.

(6) **Screw and half-nut type,** fig. 25. This is the Lavine steering gear. Adjustment is at the bottom of this device. The Jacox, page 692 is also a screw and half-nut type. The screw on both, being double threaded.



Steering Gear Adjustments.

The usual adjustments are in taking up the wear of the "worm and sector" or the "worm and pinion" or the "screw and nut." This is accomplished by bringing the two in closer contact. On the worm and worm wheel type the side play can be taken up as explained on pages 692 and 693.

Often times if gears are worn, the steering device can be turned a quarter turn and arm J adjusted to this position and a new surface will be given to the gears.

Too tight an adjustment transmits road shocks to the hands and is dangerous—about 1 1/2" play in steering wheel is usually allowed.

**See page 615 for size of brake lining for 1919 cars.

Jacox Steering Gear.

Type: Screw and half-nut type (fig'. 22 and 23). Consists of a steering tube to the lower end of which is attached a double threaded screw (S). Turning the steering wheel moves the screw (S),

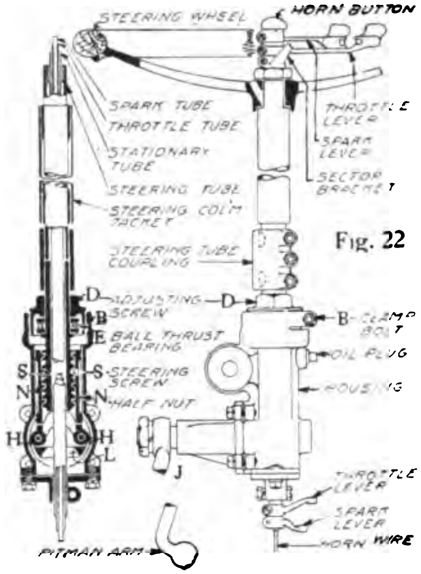


Fig. 22

which moves the two half-nuts (N). One of these nuts has a left hand thread and the other a right hand thread, therefore one half-nut (N) moves upward and the other down.

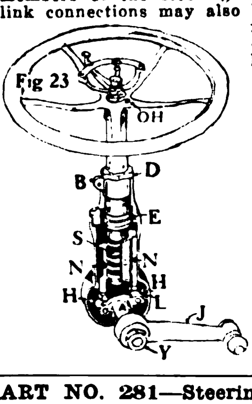
The two half-nuts (N) bear against two rollers (H) attached to a yoke (L) on a shaft (A) which projects outside of the housing and to which is attached a pitman arm (J) which is attached to the drag link, which in turn is connected to the steering knuckle arm on the front axle.

Adjustment: If excessive back lash or lost motion develops, it can be taken up by loosening the clamp screw (B) and screwing down on the adjusting screw (D) which is screwed down directly on the thrust bearing (E) which forces down the double threaded screw (S) and the sliding half-nuts (N) against the yoke rollers (H). After adjusting, lock the clamp bolt (B).

Lubrication: The gear is filled with heavy graphite grease when it leaves the factory, however, this should be thinned ocasionally by inserting a little engine oil through oil plug at top of the gear housing. The telescoping tubing can be oiled occasionally at oil holes OH, fig. 23.

Adjusting Kinks.

Hard steering is not always due to adjustment. It may be due to lack of lubrication. The other members of the steering device, such as the drag link connections may also be dry. Likewise looseness may be due to the connections. Always keep nut (Y) drawn tight.



To test for troubles; Jack up front wheels, disconnect drag link and try the gear thus disconnected. Examine drag link connections and wheel spindles. If this does not locate the trouble, loosen dash floor board bracket and see that the steering column is in perfect alignment. Take gear apart only as a last recourse.

Assembling.

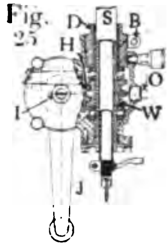
If taken apart, and the method of steering is "fore and aft," the left hand nut (N, fig. 23), should be on top for left-hand steering and the right nut on top for right-hand steering.

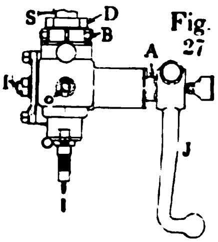
If "cross steering" method, the right-hand nut should be on left side for left-hand steering and left-hand nut on right side for right-hand steering.

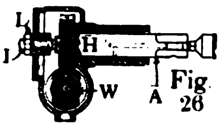
Gemmer Steering Gear.

Type: Worm (W) and worm wheel (H)—figs. 25, 26, 27.

Adjustment: End play in worm wheel shaft (A) is taken up by loosening lock nut L, (fig. 26) and taking up on adjusting nut (I).

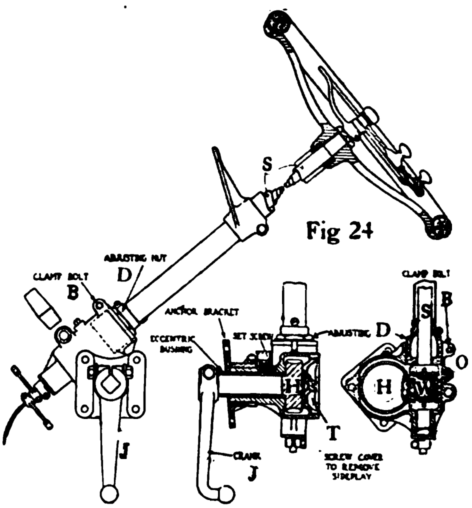






The second adjustment is made by loosening clamp bolt (B, figs. 25, 27) and tightening adjustment collar (D).

Ordinarily these two adjustments will remove any wear. However, if the wear is excessive and these adjustments will not remove the trouble, this arm (J) should be removed and steering wheel turned around so cross shaft (A) will have turned one-quarter turn. In this position place arm (J) back and it will be found that a new surface will be given to the gears. **Lubrication:** Pack with grease. Oil can be injected occasionally to keep grease from hardening.



Warner Steering Gear.

Type: Worm (W) and worm-wheel (H).

Adjustment: There are two adjustments. The adjusting nut (D) on top of steering device can be adjusted by loosening clamp bolt (B) to take up and down motion found in the wheel. The worm (W) and worm wheel (H) can be brought into closer contact by adjusting of the eccentric bushing (T).

Lubrication: Pack with grease through plug (O). Inject oil occasionally.

CHART NO. 281—Steering Devices—Types in General Use — see "Specifications of Leading Cars," pages 544 to 546, for types used on different cars.

Y.; **"Gemmer,"** Gemmer Mfg. Co., Detroit, Mich.

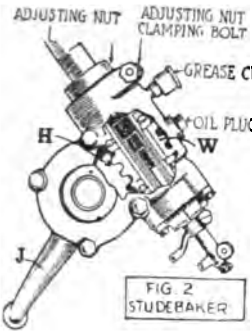


FIG. 2 STUDEBAKER

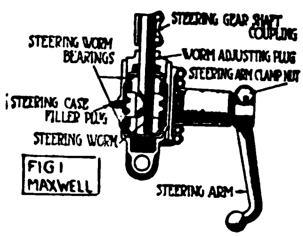

FIG I MAXWELL

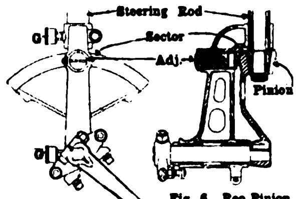

Fig. 6. Reo Pinion and Sector Type Steering Device

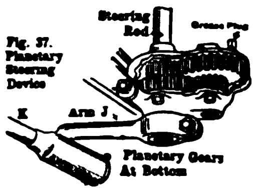

Fig. 37. Planetary Steering Device

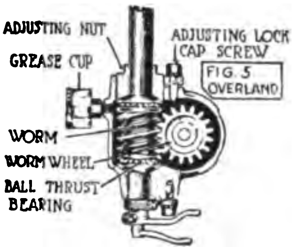

FIG. 5 OVERLAND

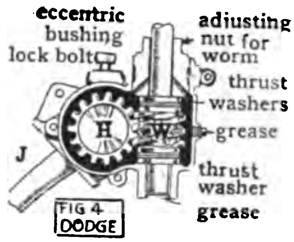

FIG 4 DODGE

Studebaker Steering Gear.

Type: "Worm and worm-wheel" (fig. 2.) **Adjustment:** Jack up the front axle so steering device will turn freely. Make adjustment with the steering wheel turned to the extreme right as though about to turn a sharp corner. There is less wear at this position than the straight ahead position, and a tight adjustment straight ahead would probably be a binding adjustment in the angle position.

In this position work steering wheel up and down. If steering column moves up or down, loosen adjusting nut clamping bolt and slowly turn down adjusting nut until all end play is eliminated then tighten clamp bolt.

If there is still back-lash it is an indication that the teeth on the worm and worm-wheel is worn. To adjust: Remove steering arm (J). Turn steering wheel one-quarter around and replace arm (J) and tighten it. This will permit the engaging of entirely new sets of teeth on worm wheel and worm gear.

Lubrication: Usually when a steering gear begins to steer hard it is due to lack of lubrication. The grease cup is used to lubricate the worm shaft bearing and heavy oil is injected at oil plug.

Chevrolet "Four Ninety."

Type: "Planetary" (fig. 37). The planetary reduction gears are at the bottom of the steering device. Cross type steering method. **Adjustment:** There is no adjustment except to see that all nuts are tight. **Lubrication:** Pack with grease.

Overland.

Type: "Worm and worm-wheel" (fig. 5). **Adjustment:** Loosen the two clamping bolts. Turn slotted adjusting to the right. Next, turn steering wheel hard around and adjust worm gear by turning the eccentric bushing. Reason for adjusting with wheel turned to right is explained under "Studebaker" above.

All Overland cars use above steering, except model "Four," which uses a "planetary" type similar to fig. 37.

Maxwell Steering Gear.

Type: "Worm and worm-wheel and has two adjustments.

If an excessive amount of end play or lost motion exists, remove the two upper bolts in the steering-gear shaft coupling and pull the steering wheel and shaft upwards. Then unscrew the steering arm clamp nut and remove the steering arm with the worm wheel shaft. The steering gear worm adjusting plug clamp screw should then be loosened and while turning the steering gear with a hand on the coupling about a quarter turn to the right and left, tighten the plug until the play is taken up.

If there is still lost motion in the steering wheel, remove the steering arm and turn the wheel until the steering arm clamp has rotated a quarter turn and replace the steering arm, thus giving the gear and worm a new bearing surface. **Lubrication:** Soft cup grease through filler plug.

Reo Steering Gear.

Type: "Pinion and sector." Illustration (fig. 6), is that of the steering device used on the Reo model "F" truck, but explains the principle as used on other Reo Cars. **Adjustment of** pinions and sector endwise may be controlled by the adj. screw. This pinion may be moved up or down by unclamping locking bolt (not shown) near bottom of steering device, allowing whole steering column to move up or down to give the right engagement. Do not disturg adj. screw when making this adjustment. **Lubrication:** Inject grease.

Dodge Steering Gear.

Type: "Worm and morm wheel," fig. 4. Both made of hardened steel. **Adjustment: To remove end play in worm shaft,** loosen coupling or shaft connection (not shown) on the steering column, also the clamping bolt at top of the steering case. Then screw down the adjusting-nut until play is removed but not too tight. Tighten the parts which were loosened.

To take up end play between worm (W) and worm wheel (H), remove eccentric bushing locking bolt. Then turn the octagonal end of the eccentric bushing, which projects through the frame, until (H) is brought in close contact with (W). Be sure to replace the eccentric bushing locking bolt, so that it sets between the teeth on the inner end of the eccentric bushing. After long usage the steering lever arm (J) can be disconnected and (H) and (W) can be rotated 90° or one-quarter turn and new teeth brought into play. Any end play found in the worm wheel shaft can be taken up by an adjustment on the side of the steering device (not shown).

Lubrication: Pack cup grease in steering gear case at grease plug, with grease gun. Turn a grease cup above H (not shown) every 100 miles.

CHART NO. 282—Steering Gear Adjustment and Lubrication. See pages 543 to 546 for make of Steering Device used on different cars.

Hudson Oiling Adjustments.

This subject is treated on pages 198 and 200. Additional matter is given below.

Evidence of Poor Adjustment.

1–Excessive and continued smoking at slow speeds. Sooty plugs.
This indicates that the central eccentric does not shorten the stroke of the pump sufficiently. Adjustment of control eccentric necessitated.

2–Oil pressure gage readings other than from ¾ to 1 lb. when idling or 2 to 2½ lbs. at high speed. Eccentric adjustment necessary, or a leak in the oil pipe lines.

3–Engine hot.
Dirty oiling system, necessitating cleaning and change of oil, with possible readjustment.

4–A pressure reading at slow speeds—none at high speeds.
Caused by the control cam permitting the plunger to work at slow speeds but stopping it at

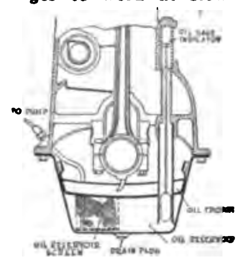

Fig 1—The oil reservoir should be drained and cleaned about every 1000 miles. If the base be removed, always clean the screen. When replacing base, have the oil trough full of oil, that the cranks may get oil from the start.

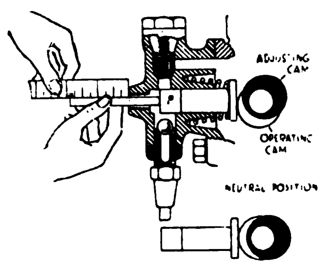

Fig 3—Left—Sectional view of the oil pump, showing method of measuring the stroke. With the engine idling, the stroke should be about 1/32 in.; when speeding, about 1/8 in. The small vertical spring at the top should be stretched or shortened until the oil pressure gage reads 2½ lbs., with the engine speeding, and the cam in the neutral position.

Fig. 4—Right—The letter C of the eccentric cross shaft should be just forward of the vertical, when the engine is speeding, in most cases of proper adjustment.

high speeds. Adjustment of cam necessary.
It is usually advisable to remove the oil pan, clean and refill with new oil in case of any oiling troubles before making any adjustments. A draining and replenishing of the oil supply is advisable every 1000 miles; or after the first 500 miles with a new car.

To Clean the System.

1–Remove oil reservoir, drain plug and drain system.

2–Remove base.

3–Remove two bolts holding oil reservoir, screen in place, and wash with gasoline or kerosene.

4–Wash oil troughs and reservoir with gasoline or kerosene.

5–Remove oil suction tube and see that it is open and clean. Blow out, if necessary.

6–Replace oil suction tubes and make all joints tight, otherwise the oil pump will draw air, preventing oil circulation and destroying the action of the pump.

7–Fill oil troughs with oil. Replace base.
If the oil troughs are not filled, the bearings etc., may not receive oil enough to prevent damage when starting the engine.

8–Refill the reservoir with new oil. This takes somewhat over 3 gals. and the indicator gage at the right of the engine should be about halfway up the column.

To Adjust Oil Pump.

1–Loosen throttle arm on pump-control eccentric at the right side of engine.

2–Turn control eccentric arm with a screwdriver until it is entirely free from plunger.
(This point can be determined when engine is idling by turning the screw (fig. 2) until a point is reached where the screw turns freely.)

3–It is then in the position shown in fig. 3, permitting the plunger to take full stroke under all conditions.

4–Speed engine up.

5–Note oil pressure. It should be about 2½ lbs.

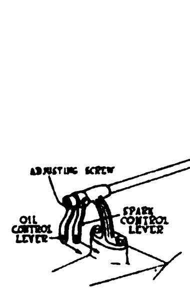

Fig 2—Control mechanism of the oil supply. Note the position of the adjusting screw at the left end of the cross-rod. The stroke of the oil pump is decreased by turning this screw in an anti-clockwise direction.

6–If it is more than 2½ lbs. stop engine, remove oil valve spring, as shown in fig. 3, and stretch it slightly.

7–Replace spring and again test.

8–Should the gage read less than 2½ lbs., squeeze the spring shorter and test.

9–Couple up throttle lever as shown in fig. 2.

10–Start engine. Let it run with closed throttle.

11–Turn adjusting screw (fig. 2) in an anti-clockwise direction until the oil gage registers ¾ to 1 pound.

12–Lock throttle lever in place.

To Check Up Adjustment.

1–Remove plug, shown in fig. 3, and insert a match or nail in the hole, bringing it into contact with the plunger head. The pump can be felt going through its stroke. (Care must be taken in doing this, as the fan runs very close to the plug and offers opportunity for injury.)

2–When the engine is idling, with the throttle closed, the stroke of the plunger should be about 1/32 inch.

3–When racing, the plunger should have a stroke of about ⅛ inch.

4–With the throttle open the mark (O) on the control eccentric arm at the coupling should be just forward of the vertical (see fig. 4).
(In making any adjustment on the oil pump, always start with the control eccentric in the inoperative position and follow the steps through as outlined, otherwise the cam may be set in the wrong position.)

Principle of Operation of The "Ball and Spring" Oil Pressure Regulation.

The method of regulation of the pressure, where a ball check and spring is used is shown on pages 198, 200, 741. The ball and spring performs the same function as a safety valve on a steam boiler. It can be placed any where on the system (preferably farthest point away from oil pump). There are certain positions of crank shaft when no oil channels register and pressure would build up excessively high were it not provided with some means of release. When pressure exceeds that at which the regulating screw is set, it forces the ball off its seat and the oil passes through channel to lubricate the chains. If this regulating screw were set at too low a pressure, then all the oil would pass out under the ball and your crank pins would go dry. If set too high the oil feed would be too great and smoke, carbon and fouled plugs would be the result.

CHART NO. 282-A—Adjusting Hudson Super-Six Oiling System—also see chart 99-A and page 200.
See page 198, 200 and 741. (Motor World.)

INSTRUCTION No. 46-C.

HOW TO USE TOOLS AND MAKE REPAIRS.

*How to Solder Aluminum.

There are various compounds on the market for soldering alrminum, but this operation depends more on the workman than on the solder, and unless considerable experience has been had it is probably better to purchase solder than to attempt making it.†

The chief difficulty in soldering aluminum is that the heat is dissipated so rapidly that it cools the soldering iron, and furthermore, aluminum oxidizes instantly upon exposure to the air. This extremely thin film effectually prevents a perfect union being made. If the parts are well heated and melted solder kept melted by allowing the iron to stand on it, the surface can be scraped beneath the melted solder by the point of the soldering iron, thus preventing to a certain extent the oxidation. In this way the metal can be tinned. When both parts to be brought together are well tinned, the parts can be united with some chance of success, nitrate of silver, resin, or zinc chloride being used as a flux.

A nickel soldering tool gives more satisfactory results than a copper one, as the latter alloys with the tin and soon becomes rough.

Parts to be united must be thoroughly cleaned: If the surface is of such a shape that it cannot be readily cleaned by scraping, it can be cleaned by dipping it into a solution of nitric acid in three times its bulk of hot water containing about 5 per cent of commercial hydro-fluoric acid. This causes a slight action on the surface of the metal as shown by bubbles. Rinse the metal after removing from the acid bath and dry in hot sawdust, or thoroughly clean and allow to stand two or three hours in a strong solution of hypo-sulphate of soda before being operated upon or cleaned in the acid bath described above.

Aluminum solder: The following formula, in the hands of a competent man, can be used to unite aluminum or aluminoid parts: tin, 10 parts; cadmium, 10 parts; zinc, 10 parts; lead, 1 part. It is best however, to purchase the solder ready made.

**Heat Treatment of Steel.

In ordinary shop practice this consists of the following: The process of **annealing**, the process of **hardening** and the process of **tempering**.

Annealing.

Annealing or softening renders metal in such condition that it can be easily cut, machined or bent. See page 713, fig. 4, showing how tubing is annealed.

To anneal steel; heat to a dull red heat and then remove from the heat and permit to cool in in the air.

Where the work is of great importance, an oven or crucible is used. A simple oven is shown in fig. 1, and fig. 1, page 696. A piece of gas pipe is used, large enough to admit the tool or metal to be heated. One end is closed and placed in coals until inside of pipe has been heated to a bright red. Then the part to be heated is placed in the pipe and brought to the desired heat. Then instead of cooling in the open air, the work is placed in a bed of non-heat-conducting material such as charred bone, asbestos fibre, ashes, lime, fire clay or sand. The metal should be left for a long period of time, well covered, until cool.

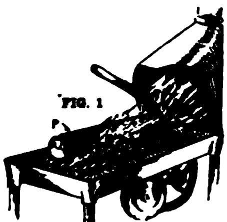

FIG. 1

Brass or copper, is heated to a low red heat and quickly dropped into cold water.

Hardening.

The process of hardening is accomplished by bringing the metal to the proper temperature, slowly and evenly, the same as for annealing, and then cooling more or less rapidly, depending on the grade of the steel being worked upon.

The degree of hardening is determined by the grade of steel, the temperature from which it is cooled and the temprature and kind of cooling bath into which it is plunged for cooling.

Steel to be hardened, is placed in the oven and permitted to come to a heat of about 650 or 700 degrees. It then is placed into a heating bath of molten lead, fused cyanide of potassium, heated mercury or some other preparation designed for the purpose. The degree of heat to which a piece of steel must be brought depends on the percentage of carbon contained within the steel. The more carbon, the lower the heat required to harden it

It is essential that the cooling bath be of the same temperature during each process of cooling.

Ordinarily, steel is cooled in water, but many other liquids are used. If cooled in strong brine, the heat will be extracted very rapidly and the degree of hardness will be much greater. If cooled in mercury, a still greater degree of hardness is obtained.

If toughness is wanted without extreme hardness, the metal may be cooled in lard oil, fish oil or neatsfoot oil.

In hardening carbon steel, bring to a cherry red heat, plunge into cold water (brine is best) and hold until hissing ceases, then remove and place in oil for complete cooling.

In hardening high-speed tool steel—see page 711.

When hardening brass, bronze, or copper, the work is accomplished by hammering or working while cold.

Tempering.

Tempering differs from hardening, in that tempering is the process of making steel tough so it will hold a cutting edge and not crack or check. Tempering makes the metal stronger and the grain finer. Tempering may be considered as a continuation of hardening operation.

To temper, the metal or tool is heated slowly, to a cherry red heat then dipped into water (fig. 3), to a depth of about ⅛ or ¼" above the point. When the piece has cooled to the point where the portion above the water has not lost its redness, remove it from the water and quickly rub the end with fine emery cloth.

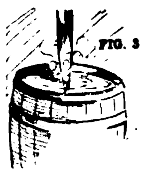

FIG. 3

While the heat from the uncooled portion of the metal gradually heats the point again a change of color occurs at the polished point. **When a certain color has been reached** the entire tool should be completely immersed in water and permitted to remain there until cold.

Colors for different work is as follows: Wood saws and springs—**dark blue, 600°**; cold chisels and screw drivers—**dark blue** or **light purple**, 600° or 520°; punches, drills and wood-working tools—**brown 510°**; taps and reamers—ordinary **straw color 450°**; lathe tools, planer, shaper and slotter tools—**light straw color**, 430°. Colors darker than the dark blue, ranging through green and gray, signify that the piece has reached its ordinary temper, which means it is partially annealed.

—continued on page 697.

*See pages 711, 712, 735 for Soldering. **A book dealing with the subject of annealing, hardening, tempering, brazing, etc., can be secured of A. L. Dyke, Pub., Granite Bldg., St. Louis, Mo. for $3.50.
†One manufacturer is Victory Aluminum Solder Co., 3384 Kedize Ave., Chicago.
*To solder cast iron, see foot note, page 712. See also, foot note, page 713.

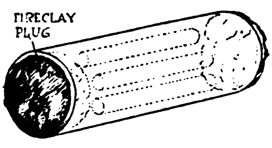

Fig. 1. Case hardening steel. The pieces are packed in a pipe with the hardening compound—but they must not touch.

***How to Case Harden Steel.**

The outer surface of any piece of soft steel may be made hard by case hardening. Its purpose is to increase the strength and wearing qualities of the steel. All machine work to be done on the steel should be done before the case hardening, as grinding alone can be done afterward. (If any part of the piece must be left soft, this may be done by covering that part with asbestos paste or paper.)

The hardening compound: Mix 9½ parts of fine charcoal with 2½ parts of table salt. Place 2½ parts of kerosene oil in a dish, and put with it as much sawdust as is required to soak the kerosene up. Now mix the sawdust and oil with the charcoal and salt. This compound may be used many times.

The crucible: Get a piece of iron pipe long and large enough to hold the pieces to be hardened (fig. 1.) Pack the pieces in this pipe with the hardening compound. Do not let one piece touch another, or touch the pipe side, but keep them well apart with the compound. Now close both ends of the tube with fire clay.

A large forge fire is necessary for heating the pipe and the pipe should be heated to a bright red heat. The length of time varies depending on the size of the pieces, and the depth of case desired.

Ordinarily two hours at bright red heat will give 1/16 inch case. This heat should be held as evenly as possible to give an even case and reduce warping effects.

To produce the maximum strength, two heat treatments are necessary after hardening. First heat each piece to a bright red and plunge in oil. Then again heat it to a dull red, and plunge. This will give a fine grain both in the core and in the case.

Quick Case hardening: If a thin case is desired, this may be applied quickly by heating the piece to redness and sprinkling the part to be hardened with potassium cyanide. Keep the temperature constant for 4 or 5 minutes, then plunge the piece in water or oil. An exceedingly thin case will result that will increase the wearing qualities of the steel, better its appearance and prevent rust.

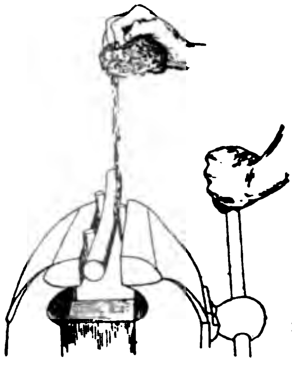
Another Method of Case Hardening.

It is possible to case-harden small pinions quite well by bringing them to a uniform bright-red heat and plunging them into finely-powdered yellow prussiate of potash, repeating the operation three or four times, and finally plunging into clean cold water whilst still at a red heat. The mild steel absorbs carbon from the potash to a depth of about 1/50th of an inch, and this surface hardens perfectly on the final cooling. Nuts so treated resist rough usage with the spanner much better than an ordinary soft-surface nut.

In treating parts of this class it is, however, important to remember that the threaded part should be filled up with clay so that it does not come in contact with the carbonizing material; otherwise it will be certain to be spoiled. Any roughness of the surface, such as on the teeth of pinions, can be smoothed off with emery cloth wrapped over a thin flat file. Parts made from tool or high carbon steel, are readily hardened by making them red-hot and plunging them into cold water. The correct heat is important, because if the parts be heated to a very bright red, they may be spoiled or decarbonized, and if to a white heat, certainly so. On the other hand, if made barely red, the parts will not harden.

Straightening Warped Pieces.

Uneven heat and uneven cooling warps the steel. Case hardened pieces can not be straightened by pressure or by pounding as this cracks the case. To straighten a warped piece of case hardened steel:



1—Find the high or "bowed" part. Mark this with a chalk line.

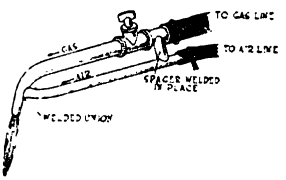
2—Heat the piece slightly—never near a red heat. (The amount of heat depends on the warp, and can only be determined by trial.)

3—Clamp the piece in a vise between the blocks as shown in fig. 2.

4—Direct stream of water at chalk line. This will contract the long side and make piece straight.

****A Home Made Gas Blow Torch.**

Small soldering jobs, especially in cramped quarters, may be most readily done by means of a blow-torch. Such a torch may be made from pipe fittings in the manner illustrated.

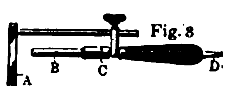


In brief, it comprises a piece of pipe, attached to the gas main by a length of rubber hose, with another piece of pipe, attached to the air line, and welded to the gas nozzle as shown. A spacer cross-brace is welded between the two pipes, at the rear, making the torch a unit. A valve on the gas pipe renders regulation of the flame easy. Though this torch is somewhat small for brazing jobs, a heavier torch could readily be made for that purpose—see also fig. 17, page 720, and 472.

†Gas Torch and Soldering Iron.

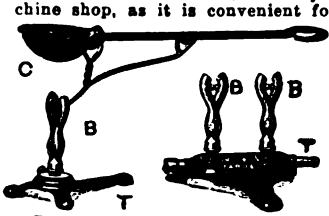
A—copper soldering iron. B—gas burner tube. C—gas burner. D—gas tube to connect hose.

This is a well-made tool. Can be used with illuminating or acetylene gas by attaching to gas burner or Prest-O-Lite tank with rubber tube. By removing the soldering iron the burner can be used as a blow pipe for brazing, also soldering aluminum — for sale by Auto Supply houses.



Starretts Gas Heater.

The heater will be found very useful in the machine shop, as it is convenient for tempering small tools, heating soldering irons, melting lead, babbitt, etc., and as a forge for light work it will be found very valuable.



Double Tube Gas Heaters

It consists of 1, 2, or 3 burners, with or without tool holder and is connected to the ordinary gas jet. A ladle 14 inches long, holding 12 ounces, can be had of the same Company. L. E. Starrett, Athol Mass.

CHART NO. 282-B—How to Case Harden Steel. A Home Made Blow Torch. A Gas Heater. Straightening Warped Pieces. (Motor World.)

*See also pages 695-697. **See also page 472. †See page 735, 711 and 712 for gasoline blow pipe torches.

—continued from page 695.

After a spring has been properly hardened by dipping in fish-oil or lard it may be held over the fire while still wet with the oil and permitted to catch fire. After the oil burns off the spring it has been properly tempered. Self-hardening steel should never be placed in water.

Drills and small tools can be tempered quite well in a flame. Larger parts are better tempered on an iron plate on which has been placed a thick layer of fine sand and the flame allowed to play underneath. This ensures the part being uniformly tempered.

Difficulty is often experienced in lathe work on nickel steel stock through the failure of the tool to retain its cutting edge. To overcome this, heat the tool nearly to white heat and plunge it into kerosene oil. See also, page 711.

Case Hardening

Is the process of hardening the surface of the steel, leaving the inside strong and tough. More carbon is added to the surface of the steel, which offers good wear—resisting qualities and has the effect of forming a very hard coat on the **outside** while leaving the inside practically unaffected. In other words the outer surface only is hardened, as for instance, gear teeth or nuts which are hardened to only about 1/50" deep—see page 696. (Motor Age.)

**Brazing.

Brazing is infinitely stronger than soldering. It is by brazing that bicycle frames are built up. Cycle makers use a gas blow flame. This consists of two parallel pipes—one for gas and one for air. The air, which issues under pressure, causes a strong and very hot flame. The air pressure is produced by a small bellows worked by the foot.

The hard solder, as it is sometimes called, is a brass that melts at a low, red heat. It is generally bought in packets, and is in grains about the size of a pin's head. Brass wire is also used. Being wound around the part to be brazed, it melts and runs into the joint. The flux used for brazing is powdered borax.

Instruments For The Automobile Mechanic.

There is one feature of automobile repairing which has been sadly neglected by the average repairman and that is, the use of electrical testing instruments for testing generators, starting motors, wiring system, ignition system and storage batteries. **Also the use of the micrometer caliper** for measuring and testing piston clearances; to see if the cylinders are out of round, etc.

The reason why neglected, is possibly due to the fact that the repairman has not realized the importance of making adjustments to a thousandth part of an inch, or else he thinks the subjects are too complicated for him to understand.

The writer would, however, advise every repairman who wishes to be "au fait" with small measurments and accurate work, to not only study the use of the instruments which will be mentioned but become the proud possessor of the instruments. You will not only place yourself in a position where you can diagnose and remedy troubles, test cylinders, pistons, valve clearances, etc., with a degree of accuracy you have not been accustomed to, but you will be in a postion to do work "over the head" of your competitor and your work will be accurate, which of course will build a profitable business for you.

*List of Instruments.

1-**Model 280 Weston Volt-ammeter,** as per page 864H. For making tests as shown on pages 402, 406, 410, 414, 416, 429, 737. Price....$	37.50
1-**Cadmium Voltmeter** with cadmium stick, as per page 864I. For testing storage battery plates as per pages 864D and E. Price......$	28.25
1-**Hydrometer,** for testing electrolyte of storage batteries, per page 450. Price..............$	1.50
1-**Wiring Manual** to aid one in tracing electrical wiring circuits, per page 864F. Price.......$	15.00
1-**No. 203 Micrometer Caliper,** for measuring spaces from .001" to 1 inch. This instrument can be used for measuring ball bearings, drills, screws, rods, sheet metal, etc., and is explained on page 698. Price................$	8.50
1-**No. 226, 3 inch Micrometer Caliper,** for measuring the diameter of pistons, etc. Will measure from 2 to 3 inches in thousandths part of an inch. **See pages** 698, 699 and page 649. Price ....$	10.00
1-**No. 226, 4 inch Micrometer Caliper,** for measuring the diameter of pistons, crankshafts, etc. Will measure from 3 to 4 inches in thousandths part of an inch. See pages 649, 609, 698, 699. Price ....$	10.75
1-**No. 226, 5 inch Micrometer Caliper,** for measuring the diameter of pistons, etc. Will measure from 4 to 5 inches in thousandths part of an inch. See pages 649, 609, 698, 699. Price ....$	12.00
1-**No. 124A Inside Micrometer Caliper,** for measuring the inside diameter of cylinders per pages 649, 609, 654, 653, 698, 699. Will measure spaces from 2 to 8 inches. Price... $	7.25
1-**No. 72 Thickness Gage,** for measuring spark plug gap clearance, (pages 235, 543); interrupter gap clearance (pages 251, 378, 543); piston ring gap clearance (pages 649, 655), etc. Has 22 leaves varying in thickness, from .004" to .025". See page 699. Price........$	2.50
1-**No. 172A Thickness Gage,** has 9 leaves and measurers smaller clearance than No. 72, as follows: .001½ or .0015"; .002"; .003" also .004"; .006"; .008"; .010"; .012"; .015". These smaller measurements are necessary for measuring ring groove clearance (page 649); valve clearances where under .004", (pages 542 and 94). Price.....................$	1.50
1-**Machinists Steel Rule or Scale,** 6 inch, per fig. 18, page 700. Price ....$	1.00
1-**Inside Caliper,** 5 inch, per fig. 6, page 700. Price ....$	1.00
1-**Outside Caliper,** 5 inch, per fig. 7, page 700. Price ....$	1.00
1-**Compression Tester,** for testing the comparative pressure of cylinders. See fig. 4, page 629. Price ....$	6.50
Total ....$	144.25

You will note that all of the above list is required, in order that one can make **all** tests. One micrometer caliper cannot be obtained that will measure all sizes of pistons, for instance, from 2 to 5 inches in diameter, instead, a **set** is required as listed above.

†Thousandth Part of an Inch.

A thousandth part of an inch is infinitesimally small but must be used to correctly measure the clearance of a spark plug gap, interrupter point gap in ignition systems and also for valve clearances as per pages 94, 542, and for many other purposes. By referring to page 698, full explanation of a thousandth part of an inch is given. See also, page 541.

See pages 712, 713. †See also, pages 698 and 541. Thousandths part of an inch and hundreths part of an inch converted into fractions of an inch, are given on pages, 541 and 115. ***Other suggested tools are: 4" machinists vice, $12.75; Blow pipe torch for soldering, $8.50; Set of drills $\frac{1}{16}$" to ½" in thirty-seconds, $7.00; Townsend grease gun, $5.50. All material listed on this page can be secured of A. L. Dyke, Elect. Dpt., St. Louis, Mo.

What is a Thousandth Part of an Inch.

If 1" is divided in 2 parts, each part is 1/2"
If 1" is divided in 32 parts, each part is 1/32"
If 1" is divided in 64 parts, each part is 1/64"
If 1" is divided in 100 parts, each part is 1/100"
If 1" is divided in 1000 parts, each part is 1/1000"

A hundredth part of on inch could be expressed in fractions, as 1/100th part of an inch, but is usually expressed in decimals as .01".

A thousandth part of an inch could be expressed in fractions, as 1/1000th part of an inch, but is usually expressed in decimals, as .001".

To read decimals, start with the decimal point (the period); call it decimal or point; next figure to right of it, call tenths; next figure, hundreths; next figure thousandths, next figure ten-thousandths, next hundred-thousandths and so on.

Thus, the figure 3 standing alone would represent three-units, but if it had a decimal point in front of it, as .3, this would represent three-tenths; if expressed thus, .03, it would represent three-hundreths; if expressed thus, .003, it would represent three-thousandths; if expressed thus, .0003, it would represent three-ten-thousandths and so on.

See page 541 for conversion of thousandths of an inch in decimals, into fractions of an inch and also page 115, for conversions of hundreths of an inch in decimals, into fractions of an inch.

If an inch space was measured off into one-thousand equal parts, each part would represent one-thousandth part of an inch or .001".

Twenty-five of these parts would represent twenty-five-thousandths of an inch (.025"), which is equal to 1/40th of an inch.

One hundred of these parts would represent one-hundred-thousandths of an inch (.100"), which is exactly equal to 1/10th of an inch.

Five hundred of these parts would represent five-hundred-thousandths of an inch (.500"), which is exactly equal to 1/2 an inch.

One thousand, or all of these parts would represent one-thousand-thousandths of an inch (1.000"), which is exactly 1 inch.

Micrometer Calipers.

It would be a difficult matter to divide an inch into one thousand divisions or graduations on a rule or scale, therefore an instrument known as a micrometer caliper with a double scale is employed for measuring spaces as small as .001". In fact, by adding a **third** scale (called a Vernier fig. 7, page 699) and computing the ratio of one figure to another, a space as small as ten-thousandths (.0010") of an inch can be measured.

The automobile repairman seldom finds it necessary to measure spaces less than .001", therefore this subject will be devoted to micrometer calipers reading .001" and more.

The three kinds of micrometer calipers the automobile repairman will need most, are shown in figures 6, 25 and 26.

By referring to page 649, note how the "outside micrometer caliper" (fig. 25, page 699) is used for measuring the outside of pistons, also, on page 649, note how the "inside micrometer caliper" fig. 26 page 699), is used for measuring the **inside** of cylinders.

The outside micrometer caliper shown in fig. 6, this page, is a smaller one, it measures spaces only from .001" to 1". The ones shown in figs. 25 and 26 (page 699) will take larger measurements, but also reads .001" to 1".

One Thousandths Micrometer Caliper.

How to read: Frame A (fig. 6) and sleeve D are stationary. The thimble E and spindle C are connected together. On the inside of A and D there are threads, (40 to the inch).

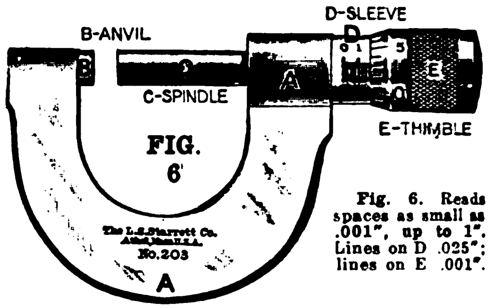


Fig. 6. Reads spaces as small as .001", up to 1". Lines on D .025"; lines on E .001".

When the micrometer caliper is closed, the end of C is against B and the bevel edge of thimble E is on the vertical line O on D, and the O line on bevel edge of E, is in line with the horizontal line on D.

When the caliper is opened, (we will assume it is closed), turn thimble E to the left. If it is turned one complete revolution, then the O line on E would have revolved from horizontal line on D, back again, and one vertical line will then be visible on D, which represents a space of twenty-five-thousandths (.025") of an inch from B to end of C (where all measurements are made).

The reason for this is due to the fact that the spindle C and thimble E are revolved on threads which are cut 40 to the inch, and a complete turn represent a movement of C, of 1/40th of an inch, expressed in decimals, equals .025" (twenty-five-thousandths) 25/1000=1/40th.

Each line, therefore, on D which is exposed, by the bevel edge of thimble E as caliper is opened, represents .025" or 1/40th of an inch. Every fourth line is longer and is numbered, 1, 2, 3, 4, etc. Therefore, if the fourth line with the number 1, (on D), is visible at the edge of E, then we would have an opening at B to C, of 4x.025" or .100", or 4/40ths, or 1/10th inch. If eight lines on D were visible, **the eighth line would be numbered 2,** and we would have an opening of 8x.025" or .200", or 8/40ths of an inch, which is also equal to 1/5".

Any fractional part of a complete revolution of E, will be read on the edge of thimble E. For instance, suppose thimble E is not revolved a complete revolution, but only a portion of a revolution. We know that a complete revolution of E represents .025", therefore there are 25 divisions or lines on bevel edge of E, equal distance apart, and every fifth line is numbered, from 0 to 25. Rotating the thimble E from one of these marks **to the next, moves spindle C longitudinally** 1/25th of twenty-five-thousandths, or one thousandths (.001) of an inch, and this is where we get the reading in one thousandths (.001)

For example, see fig. 6: There are seven vertical lines (do not count the O line), visible on D. **Multiply** this by .025 (7x.025=.175), then **add** the number of divisions or lines from O (do not count O line), on thimble E, to horizontal line on D, and we have 3 divisions or lines, (each line represents .001), therefore, we have a space from B to end of C, of (.178") one-hundred and seventy-eight-thousandths of an inch, (7x.025=.175+.003=.178).

CHART NO. 283—A Thousandth Part of an Inch (see also, page 541). **Micrometer Calipers.**

*When the symbol " is placed after a figure, as 1", it means 1 inch—see page 541. **Thickness of this paper** is .003½ (three and one-half-thousandths of an inch, or expressed as .0035" (thirty-five ten-thousandths).

—continued from page 698.

The outside micrometer caliper fig. 25, is used for measuring the outside diameter of pistons, etc. Note the frame is much deeper, which is necessary, as shown in fig. 3, page 649, so that there is room to place caliper over the piston.

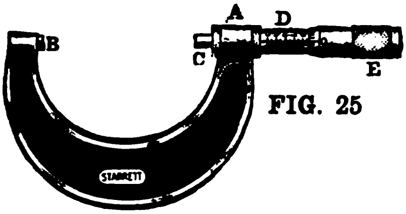

FIG. 25

The usual diameter of pistons for automobile engines, vary from 2" to 5" diameter. In order to measure pistons from 2 to 5 inch diameter, it is necessary to have three micrometer calipers, (see list, No. 226, page 697), as each caliper only reads for 1 inch measurement. In other words, the movement of O, fig. 25, is only 1 inch. This 1 inch movement can be read in thousandths of an inch as explained in connection with fig. 6.

For instance, on a caliper designed for 2 to 3", the permanent open space between end of O and B would be 2" when caliper was closed, thus micrometer reading in thousandths part of an inch would be between 2 to 3 inch. This also applies to the 3" to 4" and 4" to 5" micrometer caliper. See reference to No. 226, 3, 4 and 5 inch calipers, page 697.

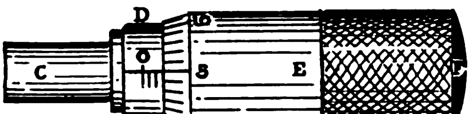

FIG. 26

To read the inside micrometer caliper, fig. 26, the same method is used, however bear in mind **that in order to read the measurement of a cylinder,** which say, is 4.080" (four and eighty-thousandths) of an inch in diameter, we would place an extension bar in the end of O (bars of different lengths are supplied with inside micrometer calipers), then open the caliper slightly more than the required amount. Then close the caliper gradually until it will go into the cylinder freely, then gradually open it until the edge of F touches cylinder wall on one side and end of bar on other side, remove and note reading, (note F is pointed, as is also, end of extension rod which fits into O, in order that they conform with curvature of cylinder).

Reading on fig. 26 shows 3 lines exposed on D, (the third line is hardly visible, but bevel edge of E is just exposing the third line on D. In fact, the spaces between lines is more often counted than the lines. Do not count line O), therefore as each line on D represents .025", we have 3x.025=.075 on D. Then count the number of lines from O line on E, (at bottom), to horizontal line on D, counting each line as .001", and we have 5 lines, or .005, therefore we have a reading of .080" (3x .025=.075+.005=.080).

Ten-Thousandths Micrometer Caliper.

The Vernier micrometer caliper (fig. 7) has a third scale and reads ten-thousandths. To read, note thousandths as in the ordinary caliper (fig. 6), then **observe numbered line on (D) which coincides with line on E. If it is line marked 1, add one ten-thousandth; if marked 2 add two ten-thousandths, etc.**

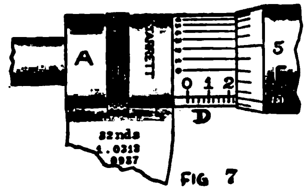

FIG 7

Thickness Gage.

This tool is used for measuring the clearance of valve stems, spark plug and interrupter points, etc. as mentioned on page 697 (No. 72 and 172A thickness gage). This is the No. 72 and has 22 leaves which vary in thickness from .004 (four thousandths) to .025 twenty-five thousandths) of an inch. See page 697 for description of the No. 172A gage.

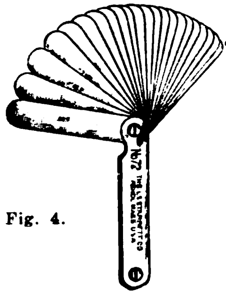

Fig. 4.

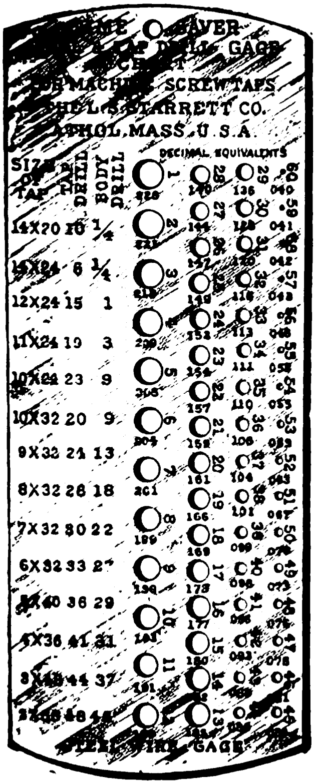
Tap and Drill Gage.



By the use of this gage one is enabled to select at once the right sized drill, to suit machine screw taps most commonly used, leaving just stock enough for tap to cut as near a full thread as is practical for one to tap without breaking it, **thus saving much time and uncertainty** of result attending the former crude ways of selection.

Explanation of illustration, the first row of figures, for an example, read thus, 14x20 10¼. The number 14 (in the first row of figures) means the number or size of tap; 20 the pitch or number of threads per inch; 10 the size of drill to use which will leave the right stock for proper thread; and ¼, size of drill to use to let this tap or screw through outside of the thread.

The figures—1, etc., up to 60—designate the number of drill (size agreeing with the holes). Other figures, 228, 221, etc., designate the size of hole in thousandths of an inch. See table No. 100, page 703, and table No. 106, page 706.

Example—Suppose you had a cap screw of a certain size and you found by referring to table No. 100, page 703, that it required a 10x32 tap. First find tap size 10x32 in column No. 1 (on the drill gage.) Referring to column No. 2 (tap drill size), you will find that a drill is required of such size as will be a snug fit in the No. 20 hole. Referring to the No. 20 hole you will note that it has the decimal .161 under it. This is the dia. of drill to use, in thousandths of an inch, and is proper size for tapping, to insure a full thread.

Suppose, however, that in this particular job you were fastening a bracket or brace to the frame of chassis, then it would be necessary to drill a large enough hole through the bracket so that the screw would pass through it (as there would be no threads required in this piece.) Referring to column No. 3 (body size of cap screw) you will find the proper size drill is the one that is a snug fit in the No. 9 hole and that the decimal size is .196 (196 thousandths.) By referring to table on page 541 of Decimal Equivalents the nearest size of these drills in 64ths can be found.

Note—In selecting a drill to drill a hole (whose dia. is expressed in thousandths) always select the nearest size to it, preferably a size or two larger. As an example take the decimals above—the first one was **161 thousandths, referring to the table on page 541, you will find that the nearest decimal to this is 171 thousandths this is equivalent to a 11/64ths drill.** The second decimal was 196 thousandths and we find that the nearest size to this is 203 thousandths, equivalent to a 13/64ths drill. **If you select a size smaller instead of larger, you run chances of breaking the tap when trying to cut the threads, especially in hard** or very thick metals.

CHART NO. 283-A—Micrometer Calipers—continued. **Thickness Gage. Tap and Drill Gage.**

*See also, pages 541, 698 for Thousandths Part of an Inch and pages 703 and 706, for Tap and Drill sizes.

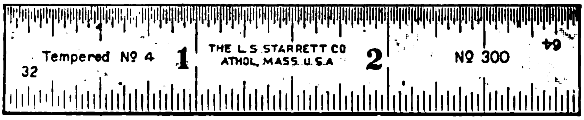


Fig. 18—A machinists steel rule or scale—These rules are of thin tempered steel and come in lengths from 2 to 24 inches long. The popular size is 6 inch, with graduations reading 64ths and 32nds of an inch on one side and 16ths and 8ths of an inch on the other side. They can also be obtained graduated in 10ths of an inch, also in millimeters as shown on page 540 and 541.

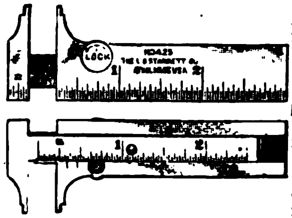

Fig. 19. A pocket slide rule, also called a caliper rule—usually made in 3 in. lengths. Graduated in 32nds on one side, and in 64ths on the other. Handy for measuring sheet or bar stock, wire, tubing etc.

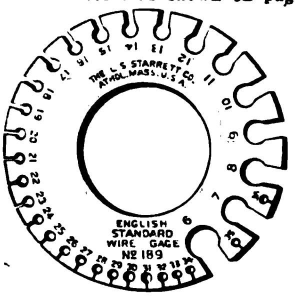

Fig. 20.

Fig. 20 — American standard wire gauge adopted by the brass manufacturers Jan. 1858. There are various gauges on the market, (some 7 or 8) and a gauge that meets the universal needs, is the kind to buy. This gauge will answer for all ordinary measurements. Decimal equivalents stamped on the reverse side.

Note— Measurements. are taken in the slots near the outer edges and not in the holes (as would appear.)

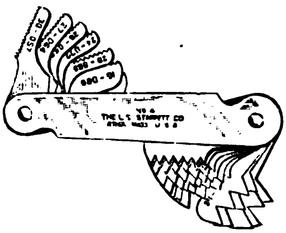

Fig. 23.

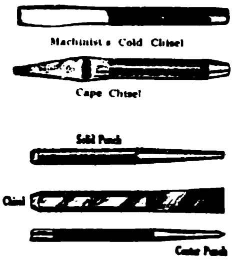
Fig. 23—Screw pitch gauge for determining the number of threads to the inch on bolts, taps, etc. The shape of the blades make it applicable also for inserting in nuts and bolt holes. Sizes and decimal equivalents stamped on each blade. This particular tool is made in pocket knife form. (see fig. 2, chart 286), showing how used.



Chisels and Punches.

A center punch is used to punch center marks in metal parts to be drilled, giving the drill a center to start in and for reference marking, etc., see lower illustrations, page 707.

Chisels are made in many forms. The most popular is the **cold chisel** which is used for cutting metals. A **cape chisel** is next most popular and is used for cutting key ways and working in narrow grooves, channels, etc.

The diamond point chisel is shown in chart 286-B. It is used mostly for grooving in close places where a cape chisel could not be used.

Other popular chisels are round nose or gouge, used for cutting oil grooves in bearings and chipping out broken bolts or pipe threads from fittings. An assortment of small chisels and punches shown in fig. 24.

Fig. 24—The best way to buy chisels is in sets.

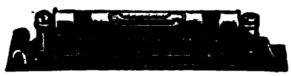


Fig. 21. Spirit level used for lining up pistons, connecting rods, etc., when used in conjunction with a steel square. (see chart 261) also used for finding grades as shown on page 539.

†Fig. 22. Speed indicator, or revolution counter as it is sometimes called, is a necessity in high speed work. The dial can be set at the 0 mark and when timed with a watch for a minute or fraction thereof, will give the total revolution made by the crank shaft, line shaft, motor or generator.

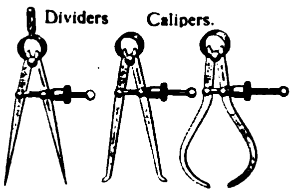

Fig. 5. Fig. 6. Fig. 7.

Fig. 5—Dividers are used to lay off circles and distances on metal. (see chart 286-B.)

***Fig. 6—Inside calipers** are used for measuring inside diameters, such as cylinders, bearings, etc.

Fig. 7—Outside calipers are used for measuring exterior diameters such as drill taps, etc. The caliper is adjustable and after measurement is taken the points of caliper are placed on a rule or scale to find the measurement in inches or fraction thereof.

Caliper dividers are made with and without springs—the spring is an advantage inasmuch as when once set they retain their setting. The non-spring type is shown on page 614.

Fig. 29—A hook rule for measuring diameter of flanges or circular pieces, through the hubs of pulleys, setting calipers or dividers etc.

Fig. 25—A scriber—used for scribing fine lines on planed surfaces of iron or steel, such as timing marks on fly wheels, etc. Points are of tempered tool steel.

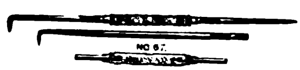

Fig. 26—Double point scribers threaded to screw into the holders and knurled for finger grip.

CHART NO. 284—Measuring Instruments, Chisels and Punches.

***See page 649 for micrometer calipers** for measuring **outside** of pistons and **inside** of cylinders. **†Method of using this indicator** is to place end into a recess, which is usually at end of all shafts. A watch is held in one hand and number of revolutions per minute is shown on indicator.

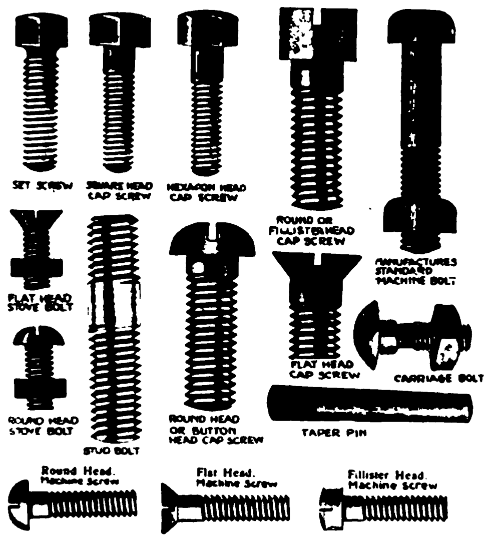

Fig. 1—Illustrations showing the different kinds of bolts and screws. The square head cap screw is seldom used. (see chart 247-DD.)

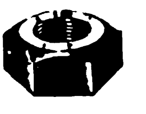

Fig. 2.

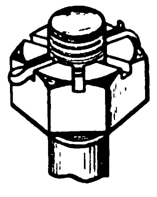

Fig. 3.

Fig. 2—A hexagon nut.

Fig. 3 — A "castellated" nut. The castellated nut is also hexagon but nut is slotted to take a cotter pin to prevent it coming loose.

Fig. 4.

Fig. 5.

Fig. 5—S. A. E. Standard cap screw and bolt thread. These exaggerated illustrations are intended to show the only difference between a U. S. S. cap screw and an S. A. E. cap screw—which is in the thread. Note fig. 5—(S. A. E.) the thread is much finer, therefore more threads per inch.

By referring to table 101, chart 285-B, note a ¼ inch U. S. S. cap screw has 20 threads per inch. Whereas a S. A. E. cap screw (table 102, chart 285-B) has 28 threads per inch.

Bolts, Screws and Nuts.

Nuts are not usually used on capscrews as the cap screw is generally screwed right into the metal part. However, nuts can be put on to them and they be used in place of bolts.

Bolts always have nuts on them either square or hexagon and in most cases the nuts are larger than the head and consequently take a different size wrench—for instance a ⅝ machine bolt has a 1$\frac{1}{16}$ inch head and a ⅝ nut. Whereas an S. A. E. ⅝ cap screw has a $\frac{15}{16}$ inch head. (see chart 247-DD.)

The measurement for the diameter of a bolt or screw, is taken just below the head, where the metal is full diameter. If measured across the threaded part, they will be found to be of slightly less diameter due to the "flat." (see fig. 3, chart 285-A.)

U. S. S. & S. A. E. Bolt and Cap Screws.

The U. S. S. and S. A. E. cap screws are alike in all respects, with the exception of the pitch diameter and number of threads per inch. By referring to table No. 102, chart 285-B, you will notice the number of threads to the inch on the S. A. E. is more than on the U. S. S. (table 101).

On the auto we find bolts are used on the springs and various parts. In fact there is hardly a part of the entire mechanism that does not have its quota of bolts, capscrews, machine screws or carriage bolts (latter used for holding body to frame.) Stove bolts are used frequently for fender and drip pans.

Difference Between Bolts and Cap Screws.

The difference between a capscrew and a machine bolt, is mostly in the method of manufacture. In making a capscrew the usual method is to cut off a piece of the required length, from a piece of steel of hexagon shape and of the size required for the head, the piece is then turned down to the size required for the body and a thread cut on it (or it is milled.) In making a machine bolt, the stock is cut from a bar of round steel of the required diameter of the body and the head is then formed by a process called "upsetting." The machine bolt has a slightly larger diameter head than the cap screw but the threads are indentical in both.

The only difference between an S. A. E. bolt and an S. A. E. cap screw is in the amount of thread cut on it. The size and shape of head is the same and threads per inch is the same.

The difference between a U. S. S. bolt and a U. S. S. cap screw is also in the length of thread and the size of head. The thread on a cap screw is run down nearly to the head while on a bolt it is run down only about ⅓ of its length. The heads differ in that the bolt head is larger than the cap screw head and in the former is usually square instead of hexagon.

The difference between a machine screw and a machine bolt is mostly in the shape of the head. The screw has either a round or a flat head, but never a hexagon head and differs in the further respect in that the head is slotted for the reception of a screw driver.

A wrench that fits a U. S. S. cap screw **will fit** an S. A. E cap screw, because the heads are of the same size.

A wrench that fits a U. S. S. machine bolt **will not** fit an S. A. E. cap screw, because the U. S. S. bolt head is larger.

A wrench that fits a U. S. S. cap screw **will fit** an S. A. E. machine bolt, because the S. A. E. bolts have the same heads as cap screws.

A wrench suitable to fit any and all of the above is the adjustable S wrench, and open wrenches in sets. (see page 611.)

Studs, Taper Pins and Set Screws.

Studs are usually placed in the top of cylinders with detachable heads. The cylinder head is slipped over the studs and fastened down with hexagon nuts.

They are also used on top of crank case—see page 64 (E-117).

Taper pins require taper pin reamers—a reamer must always match the pin. (see page 706, for a taper pin reamer). Taper pins are used for—locking collars to shafts (where keys cannot be conveniently used), and various other purposes.

Set screws are usually cut full, so as to fit tight in the part to be held. They are either pointed or cupped at their lower ends and are either square headed or slotted. In using, set up tight and tap them directly on top with a light hammer, then tighten again. This will set the point or cup in the shaft. The threads are always U. S Standard.

When driving out bolts that are to be used again strike the hardest blow you can and use a heavy hammer. Light blows and the use of a small hammer will upset or rivet the bolt.

CHART NO. 285—Different Kinds of Bolts and Screws—also see pages 611 and 612 for wrenches 238 for spark plug sizes and wrench sizes, 239 for spark plug gaskets. Page 611, gives the sizes of S. A. E. screws and bolts.

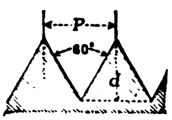

Fig. 1.

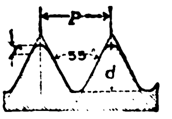

Fig. 2.

Fig. 1.—The sharp V thread (U. S. S.)

Fig. 2.—Whitworth's standard (oval). Note thread does not come to a point either top or bottom.

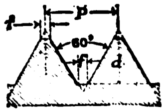

Fig. 3.

Fig. 3.—The U. S. S. (United States Standard) and S. A. E. thread. Note the **flat at top of thread.** This is also called the A. S. M. E. thread.

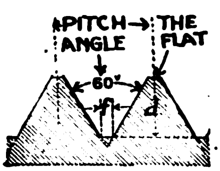

Fig. 5.

Fig. 5. — Explains the meaning of "pitch," "angle" and "flat." The pitch is the distance from one thread to another. The "angle" is the degree of slope and is usually 60° except Whitworth which is 55°. The "flat" is the top of thread coming to a flat instead of to a point.

Brigg's standard thread which is only for pipe, is oval like the Whitworth.

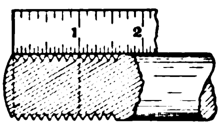

Fig. 6.

Fig 6. — The number of threads to an inch can be measured as here shown, or with a screw pitch gauge as per fig. 6, page 705.

The pitch is the number of threads per inch.

A screw pitch gauge (fig. 23, chart 284) is a quicker and more accurate method for finding the number of threads per inch.

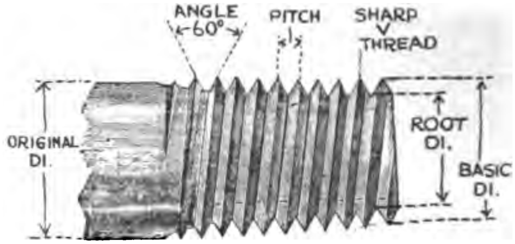

Fig. 8.—Explanation of the thread: Note the **original size** of stock on which thread was cut. Then note **meaning** of "angle," "pitch," and "V-thread." The "root **diameter**" is measured from base of threads and the "basic **diameter**" is measured from top of flats. (Used in this illustration, merely to explain its meaning.)

Threads.

The two principal threads the repairman or mechanic should familiarize himself with, are the **bolt thread** and the **pipe thread.** A little study and use of the various sizes will enable him to know the particular kind and size by merely looking at it. A comparative difference in size between a bolt tap and a pipe tap is shown in figs. 14 and 15, page 704.

Note how much larger a ⅜ pipe tap is than a ⅜ bolt tap. This is due to the fact that a ⅜ pipe is measured on the inside and twice the thickness of the metal (of which the pipe is made) must be added to the ⅜" to get the diameter required. In the bolt tap the measurement is taken on the outside, consequently the tap is of practically the same diameter as the bolt.

U. S. S. and S. A. E. Used Most.

***The threads most commonly used in this country are the United States Standard and the S. A. E. formerly A. L. A. M.** This latter is the standard adopted by the (Society of Automobile Engineers) for automobile work.

The diameter and angle of the S. A. E. thread is the same as the U. S. Standard, the only difference being in that the S. A. E. thread is of finer pitch (see fig. 5, chart 285), or more threads to the inch. Take for instance a U. S. standard ¼" screw, it has 20 threads per inch, while a ¼" S. A. E. screw has 28 threads per inch (see tables 101 and 102, chart 285B). This finer thread has been found by experience and tests to have several advantages over the coarse U. S. S. thread in auto construction, one of which is the incessant vibration to which a fast moving automobile is subjected to. A nut with fine threads takes more revolutions or turns to remove it than one with coarse threads and the chances are that were the threads coarse the nut would be far more apt to be lost, whereas the fine thread nut with the same number of turns would be only loose. There are various other reasons, of as much or more importance which led the manufacturers to adopt this finer thread.

The fine thread is nearly always used where hardened material is employed (as case hardened) and the coarser thread where soft material—as aluminum, brass, bronze, etc.

Other thread standards used somewhat in this country (although they are made principally for foreign business) are the Whitworth Standard (fig. 2) and the Metric or French Standard (not illustrated).

***Pipe Threads.**

The Briggs Standard (table 103) is for pipe work only and has no connection with screw work.

Pitch of thread; by this is meant the number of threads per inch, or the distance from the top of one thread to the top of the next. This pitch is always the same for the same size bolt, nut, tap or die of the same standard.

To Find the Pitch or Threads Per Inch.

To find the pitch of a screw when a thread gauge is not convenient, place a scale on the screw (fig. 6) so that the end of the scale is opposite the top point of any thread; count the number of spaces under the scale between the threads, for a distance of one inch, viz.: There are eight spaces underneath the scale in one inch, therefore, the screw is ⅛" pitch or eight threads per inch. **Another method** is to place the scale as shown in fig. 6, and count the top of the threads for a distance of one inch, omitting one thread. The reason for omitting one thread may be seen by following the two dotted lines drawn from the top point of the first and 9th threads; count the number of complete threads between the dotted lines at the bottom of the screw, and you will find it to be eight.

Pitch angle; by this is meant the angle or degree of slope that the sides of the individual threads have and is always 60° in the various standards with the exception of the Whitworth which has 55°. This angle clearly shown in fig. 2. **Flats:** see fig. 3—note U. S. S. and S. A. E. use this thread—but while the angle and flat are the same, the S. A. E. is of finer pitch or more threads per inch.

In tables 101 and 102, chart 285-B, a tabulation of sizes and threads per inch, from ¼" to 1" for U. S. and the S. A. E. standards, **also the drill size to use for drilling a hole preparatory to tapping** or cutting the threads is given.

Root Diameter Determines Drill Size.

Root diameter; means the diameter of the bolt measured from the bottom of one thread to the bottom of the thread diametrically across from it and is the measurement that must be taken into account when figuring the working strength of the bolt and **is the diameter that gives you the drill size.**

In practice the drill size is a little larger, so that after a thread is cut it will be found that it is not really a full thread, but is full enough for all practical purposes if drill is not unnecessarily large.

*The sharp V-thread, fig. 1, with its razor like edge, is a thread the manufacturers do not favor. The flat thread, fig. 3, is the one favored.

†The length of a thread on a cap screw is more than on a bolt.

CHART NO. 285-A—Threads; Different Kinds. How to Find the Number of Threads per Inch, etc.

*See page 608 for outside and inside dimensions of pipes.

TABLE NO. 100.

Size of tap and drill to use for U. S. S. (United States Standard) or A. S. M. E. (American Society of Mechanical Engineers) —screw thread.

First and sixth column gives the size tap designated in numbers; **Second and seventh column**, the outside diameter of tap; **Third and eighth column** the number of threads per inch; **Fourth and ninth column** the size drill expressed in decimal parts of an inch; **Fifth and tenth column** the number, or size of drill which is necessary to drill the hole for the tap.

Example: suppose, on the tap the numbers 14-20 appeared. This would mean that the tap number was 14 and 20 is the number of threads per inch. Therefore by referring to the sixth and tenth column, the size tap to use would be No. 14 and the size drill to use for this tap would be No. 10 drill which is .1932 inch diameter. see page 706 explaining drill numbers and page 705 explaining tap numbers.

Size of Tap	Outside Diam	Threads per Inch	Nearest Commercial Size Drill producing 75% depth of thread: Inch Decimals	Commercial Designation	Size of Tap	Outside Diam	Threads per Inch	Nearest Commercial Size Drill producing 75% depth of thread: Inch Decimals	Commercial Designation

9	.177	30	.1445	27	30	.450	14	.3804	V

NOTE: A common nut, drilled out so that it only contains 50% of a full depth thread will break the bolt before it will strip.

A 75% depth of thread yields an ample margin of safety (2 to 1) and is economical in tapping.

A full depth of thread in a common nut is only about 5% stronger than a 75% depth of thread: yet it requires three times the power to tap.

Note—A ¼ inch S. A. E. tap is larger in dia. than a U. S. S. ¼ inch tap, due to the difference in the root diameter of the bolt or screw. see page 702 explaining root and basic pitch.

How drills are designated; refer to table No. 106, page 706 which explains how certain sizes of drills are lettered instead of numbered etc.

TABLE NO. 103.

Tap and drill size for pipe threads. This table gives the size drill to use for a certain size pipe tap. The Briggs standard is the one used in this country. Note the threads on a ¼ inch pipe tap are 18 to the inch, whereas on the S. A. E. (table 1 0 2) there are 28 and on the U. S. S. (table 101) there are 20 threads per inch.

Size Tap Inches	BRIGGS STANDARD: Thread	BRIGGS STANDARD: Drill
1/8	27	21/64
1/4	18	27/64
3/8	18	9/16
1/2	14	11/16
5/8		
3/4	14	29/32
7/8		
1	11½	1 1/8

Table No. 103.

The diameter of a pipe tap is larger than a stated size of any other tap—see page 704 explaining why.

TABLE NO. 101.

Tap and drill sizes for U. S. S. threads—This tables gives the diameter of tap and threads per inch and size drill to use (expressed in common fractions) for the tap. The diameter of the tap expresses the screw size. For instance a ¼ inch tap is for a ¼ inch screw with 20 threads—therefore the size drill to use would be 5/16 inch, etc.

Example: To find what size and number tap to use for a ¼ inch U. S. S. bolt with 20 threads to the inch. First find the decimal equivalent of ¼ inch (page 541.) ¼ inch is equal to 2/8 inch, so by looking in column under heading of 8ths, you will find that ¼ or 2/8 is equal to 250 thousandths or point 250. Referring back to (table 100) find the nearest decimal, this will be found in column No. 7 and can be either .242 or .268 so you could use either a No. 14 or a No. 16 tap .

To find what would be the number of the drill for a ¼ inch U. S. S. tap, 20 threads to the inch. Proceed as in the previous instance, first find the decimal equivalent of ¼ inch. This you have found to be 250 thousandths. The nearest decimal to this is in column No. 7 and can be as before, either .242 or .268 and the proper drill corresponding thereto is found in column No. 10 and can be either a No. 10 drill or a 7/32 inch drill. You will notice by referring to (table 101)—that a 3/16 inch drill will also answer.†

Diam. Tap in Ins.	Thds. per inch	Size of Drill Ins.	Diam. Tap in Ins.	Thds. per inch	Size of Drill Ins.	Diam. Tap in Ins.	Thds. per Inch	Size of Drill Ins.
1/4	20	3/16 in.	9/16	12	29/64	1 1/4	7	1 5/64
5/16	18	1/4 in.	5/8	11	33/64	1 3/8	6	1 11/64
3/8	16	5/16 in.	13/16	11	37/64	1 1/2	6	1 19/64
7/16	14	3/8 in.	3/4	10	5/8			
1/2	13	11/32 in.	11/16	10	11/16			
1/2	12	13/32 in.	7/8	9	47/64			
			15/16	9	51/64			
			1	8	27/32			
			1 1/8	7	61/64			

Table No. 101.

Note — The only difference it would make in using one or the other of the various drills, would be in the fullness of the thread. The larger the drill the less depth of thread. You can readily see that by using a drill too large you would cut away the metal that should go to make the thread and on the other hand, if you use a drill too small, you would not be able to enter the tap. (See foot note bottom of table 100).

TABLE NO. 102.

Tap and drill size for S. A. E. This table gives practically the same information as table No. 101—but for S. A. E. cap screws. The first column gives the size tap to use, second column, the number of threads to the inch (pitch); the third column, size drill to use.

To find what number of tap would be required or the number of drill, would be the same procedure as in table 101. The diameter of drill and tap would be the same as for the U. S. S. but the number of threads per inch would be greater, as would also be the root diameter. A comparison of the two drills for the 5/16 taps for instance will make this clear.

Diam. in.	Pitch	Tap Drill
1/4	28	No. 4
5/16	24	17/64 in.
3/8	24	21/64
7/16	20	3/8
1/2	20	7/16 in.
9/16	18	1/2
5/8	18	9/16
11/16	16	39/64
3/4	16	43/64
7/8	14,18	51/64, 13/16
1	14	59/64

Table No. 102.

*No. 4 drill is 7/32 inch. *The 7/8—18 threads is for S. A. E. spark plug.

†In practice it is best to use a larger size drill, if the exact size cannot be had.

CHART NO. 285-B—Tables Giving the Tap and Drill Size to Use for U. S. S., S. A. E. and Pipe Threads. See page 612 for S. A. E. and U. S. Standard screw and bolt tables and S. A. E. spark plug sizes.

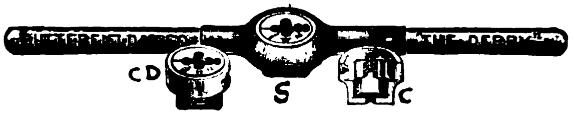

Fig. 8—Methods of cutting male threads are with a die and stock, or on a lathe. When a die and stock is used, it is placed in a collet (C) and the collet and die (CD) are then placed in a stock (S). This is worked over the part to be threaded. The illustration shows a die and stock for cutting threads on machine screws.

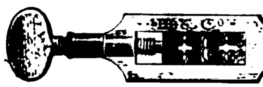

Fig. 8-A—A screw plate or gunsmith's die. It cuts threads in the same manner as the one shown in fig. 8, but there is no collet. Bicycle dies are often made in this form.

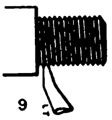
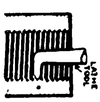
Fig. 8-B—A stock and die for cutting threads on pipe. The pipe is held stationary and tool revolved. Note projection at bottom to hold die to pipe.



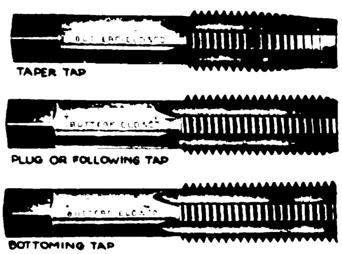
9

Fig. 9—Threads may also be cut on a lathe, note the lathe tool cutting an outside or male thread.



12

Fig. 12—Note lathe tool cutting an inside or female thread. The tool is held stationary. Just the reverse of hand cutting.



TAPER TAP

PLUG OR FOLLOWING TAP

BOTTOMING TAP

Fig. 13—The machinists hand taps are explained in the text.

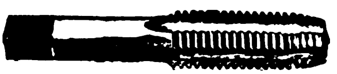


Fig. 14. A ⅜" machinist's tap.

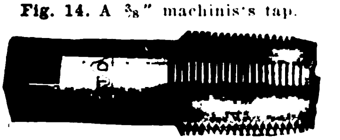

Fig. 15. A ⅜" pipe tap.

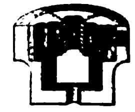
Fig. 14 and 15 are illustrations intended to show the comparative difference in size between a ⅜ machinists hand tap and a ⅜ pipe tap, as explained in text.

Die without Collet



SECTIONAL VIEW COLLET AND DIE

Dies.

The subject of dies is really a part of the tap subject inasmuch as where the one is used, the other must be used also. The tap cuts a thread on the **inside** and the die cuts the companion thread on the **outside**. Thus you would **"tap a hole"** or nut and **"run a die over"** a bolt or pipe.

With dies as with taps, they are divided into two classes, **pipe dies and bolt dies.**

The better grade of dies are adjustable as to size, that is, you can make them cut a little larger or a little smaller than "standard." This will be found to be of special value in repair work.

The solid die is non-adjustable and when worn will not cut deep enough, as a consequence the nut or fitting is nearly ruined by forcing it on. It sometimes happens that a cutting lip is broken off; this necessitates the purchase of an entire new die, whereas in the adjustable die one can renew—just the broken lip—at slight expense.

How marked: Dies are marked as to size, **threads per inch** and whether **right or left hand thread,** designated by the letter R or L. In a great many instances it is both necessary and convenient to cut a left hand thread and it is advisable to have a few of the most used sizes on hand. (A brake rod for instance, where it screws into the turnbuckle has a left hand thread).

Dies and their corresponding taps are so made relative to the diameters at the top and bottom of thread, that when the nut is screwed onto the bolt, the extreme tops do not touch one another, in other words there is a small space allowed, called the **clearance** (about .002 inch.) The real bearing surfaces are the angular sides of the thread. This clearance space is accountable for the rust that is found in the threads of old bolts and nuts and it is in this space that the kerosene soaks in, when applied to loosen up a rusty nut.

See page 612 for illustration of a set of dies of various sizes and also the stocks in which they are used—also tap wrenches.

The stock—is the holder for the die while cutting and usually has removable handles.

Screw plate set is a term used to express the entire outfit, as shown on page 612. Although we have shown fig. 8 as a die and fig. 8-A as a screw plate—the term is used as above stated.

Screw Taps.

Taps may be divided into two distinct groups; bolt and pipe taps.

Machinists hand taps are used for cutting internal threads in metal and are usually bought in sets of 3, viz: taper, following, and bottoming.

Pipe taps are used for cutting threads in pipe fittings and cutting threads for the insertion of pipes, pet cocks, drain plugs, etc. (see fig. 15, also table 103, page 703. See also, page 608.

The taper tap: (fig. 13, also No. 1, chart 286) so called owing to its sides being tapered is the one first used after hole is drilled. This is in reality a roughing tool and does not give a full thread unless run all the way through. It is used for open work such as the truing up of the threads in a nut and also for tapping various parts of the chassis.

The following tap: (fig. 13, also No. 2, chart 286) is next used and in the majority of cases is all that will be required to finish the tapping process. Where tapping is done in solid metal, this is the one generally used. If threads are desired, clear to the bottom of solid work, then the bottoming tap is used.

The bottoming tap: (fig. 13, also No. 3, chart 286.) In many instances, the thickness of the metal is such that a tap cannot be run in far enough to cut a complete thread all the way to the bottom of the hole, it is therefore necessary to use the bottoming tap. There is no taper to this tool, consequently it cuts full size from start to finish and thread must be started with one of the other taps first.

Flutes: This term applies to the grooves cut in the sides of taps for the reception of iron cuttings or chips and any foreign matter that might be present whilst cutting. It is the almost universal practice to make taps with 4 flutes, as shown in end view, fig. 2, chart 286, this makes it convenient to caliper the diameter—which otherwise could not be so easily done if there were 5 or any other odd number of flutes.

CHART NO. 285-C—Cutting Threads. Stocks and Dies. Taps. Comparison of Bolt and Pipe Taps.

—continued from page 704.

U. S. S. & S. A. E. Taps.

Sizes of tap: After proper size hole is drilled, it will be then in order to get the proper size and standard of tap necessary to cut the thread. Suppose you wished to tap a hole to fit a 3/8" S. A. E. screw. If you drilled the hole of such size as called for in table 102, page 703, you would have used a 11/32 inch drill, therefore you would call for a 3/8 inch S. A. E. tap. If the bolt or stud was the U. S. Standard 3/8 inch size, use a 5/16 inch drill as per table 101. (Note that the S. A. E. tap is 1/32 inch larger than the U. S. S.) page 703 and use a 3/8 inch Standard tap. If, on the other hand you are working on a 3/8 inch pipe job instead of a bolt job, you would have used a 19/32 inch drill (see table 103, page 703) therefore use a 3/8 inch pipe tap. Notice that the drill used for a 3/8 inch pipe tap is nearly twice as large as that used for a Standard bolt of the same size, see figs. 14 and 15, page 704, for relative size.

Taps How Marked.

You will find on all taps, at least 2 marks; they refer to the diameter and the threads per inch. Thus, a tap marked (1/4-20 or 1/4-28) will denote that the tap is for 1/4 inch size nut or hole and has 20 or 28 threads per inch. The (1/4-20) is a U. S. S. tap and the (1/4-28) is an S. A. E. tap.

A great many taps are marked with a number instead of a fraction thus, (14-20) this means that the number of the tap is 14 and the threads are 20 to the inch. In (table 100, page 703) is shown a complete list of tap numbers from 0 to 30. Those marked with a + mark are the sizes most used for ordinary work. The table also gives the proper size of drill to use with the various taps. The dimensions are given in thousandths of an inch. By referring to table on page 541 of "Decimal Equivalents" you can get the proper size in fractions of an inch.

Tap Sizes.

Sizes of numbered taps: Taps from No. 1 to 30 run from 1/16 to 7/16 in. outside diameter, varying approximately by 32nds.

Numbers above 30—are marked according to the size and thread; for instance a 1/2 inch tap (U. S. S.) would be marked (1/2-13), meaning 1/2 inch size and 13 threads to the inch. When taps are marked in this manner they run from 1/4 inch to 1 inch, varying in 1/16 of an inch sizes or fractional part of an inch.

Size taps most used—a set for small work; would be from No. 1 to 14 (page 703, table 100), which runs from 1/16 to 1/4 inch with variations by sixteenths, then from 5/8 to 1 inch, varying in eighths of an inch. Taps are seldom used over 1 inch for general auto work.

*Special Taps for Spark Plugs.

For regular 1/2 inch size (fig. 4, page 288), with 14 threads per inch, use the regular standard 1/2 pipe tap and a drill 23/32 inch (see table 103, page 703.)

For S. A. E. 7/8 inch size with 18 threads per inch, use the S. A. E. 7/8 inch "special spark plug tap." Note by referring to table 102, page 703, that the standard 7/8 S. A. E. screw tap has 14 threads—and the S. A. E. spark plug has 18 threads. It is for this reason that a special tap is required. A 13/16 inch drill is the proper size to use.

The metric 18 m. m. size uses the metric 18 m. m. spark plug tap. (French Standard).

See page 612 for S. A. E. spark plug dimensions, and 239, 607 and 717 for spark plug gaskets.

How To Use Taps.

Before using a tap, the hole must be drilled to the proper size, as given on page 703. Never use a monkey wrench or an S wrench unless in a tight corner—as there is a liability of breaking the tap.

Get the work perfectly level and rigid before starting the tapping—and start tap true.

When tap is caught, sight or use a square (fig. 3) to see if it is true; and if not, turn the tap backward, and then forward pressing in the direction required to straighten on the forward stroke only.

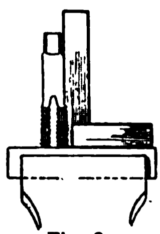


Fig. 3.

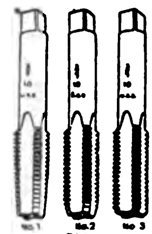

FIG. 1

Start the taping with a No. 1 tap, or "taper tap" followed by the No. 2 or "following" tap, and if threads are desired a little large, or particularly clean, and to the bottom of a hole, then use the "bottoming," or No. 3 tap. (See page 704 for meaning of "taper", "following" and "bottoming" taps.) **Fig. 1,** above shows the three taps.

Lard oil should always be used on taps, or dies, never a mineral oil.

Brass or cast iron requires little oil; steel, a continued application, and the tap should not be forced during the cutting. If the tap sticks, backing off, and starting over will usually permit the tapping to be done with little exertion.

Several methods are commonly employed to make a tap cut oversize. One is to pack the groove with cotton waste; another to place a thin strip of copper or brass over one cutting lip, and another to place the tap in boiling water, and cut the thread while the tap is still hot. Of the three, the first is perhaps the best method.

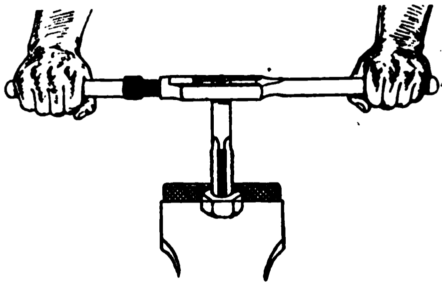

FIG. 4

Fig. 4—The tap should be started square, and with even pressure on each arm of the "tap wrench".

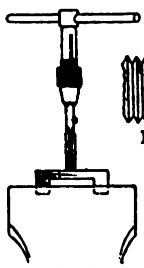

FIG. 5

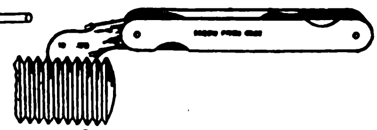

Fig. 6.

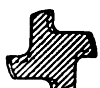

FIG. 2

Fig. 5— A large tap and reamer wrench (fig. 4) should never be used for small taps. Use the small "hand-tap-wrench" illustrated in fig. 5.

Fig. 2—End view of a regular type (4 flute) tap. See last paragraph, bottom of page 704 for meaning of "flute".

Fig. 6—Illustrates a screw pitch gauge, similar to fig. 23, page 700.

CHART NO. 286—How to use Taps for Tapping Threads. Screw Pitch Gauge.
(Motor World.) *See also, page 612.

Drills.

Twist drills are the kind always used for boring in metals. They are generally made with two flutes or spiral grooves, for the reception of the cuttings or chips of the metal being drilled.

Flute drills are those having flutes or grooves arranged longitudinally along their length. They are mostly used for soft metal and are the kind which usually come with hand drills in small sizes.

Shanks—the part that goes into the chuck is called the shank. The shanks most generally used for a power drill press are either straight or taper.

Straight shank drills are used in lathes or in drill chucks. For instance, where a straight shank drill is desired to be used in a power drill press which takes a taper shank only—then a taper arbor (B) can be fitted in end of **drill chuck (C) and the tapered end of taper arbor (A) can be inserted in the drill press. This method is usually employed where the drills are ½ inch or less.

Taper shank drills fit into the drill press without the use of drill chucks.

Taper Shanks.

Taper shanks on drills vary—therefore, drill presses are usually fitted with four sizes of taper shanks as follows:

For drills 1/16 to 9/16" with No. 1 taper shank.
For drills 37/64 to 29/32" with No. 2 taper shank.
For drills 59/64 to 1¼" with No. 3 taper shank.
For drills 1 17/64 to 2" with No. 4 taper shank.

*How Drills are Designated in Sizes.

Note table 106. You will observe that in the sizes from 1½" to No. 80—(0.013 or 13/1000ths of an inch) the drills are numbered and lettered. The No. 80 is the smallest size. In other words, the larger the number, the smaller the drill. (see also Drill Gauge, on page 699.)

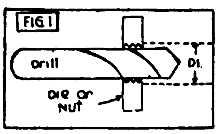
Drills from No. 80 to No. 1 (1/64th to 7/32nds) do not bear size numbers or letters marked on them, but are measured on drill gauges per chart 283-A.

Drills from No. A to Z (¼ to 13/32nds) have their size designated by letters stamped on their shank.

Drills from Z to 1½ inch, the actual size is stamped on them, as 27/64 to 1½.

Comparison of table 106 and table 100. The exact size of a No. 30 drill, for instance as given in table 106, is 127 thousandths of an inch and in table 100, 4th column it is given as 131 thousandths. This difference is only slight and does not affect the strength of thread. This difference is due to using tables of actual drill size (table 100), and table of drill rods (table 106).

Fig. 1—One method for finding the size drill to use for tapping, is to select one that will be a sliding fit in the die which goes with the tap. If the drill is too large to



go into the die (a nut will do just as well) the threads will not be full and if it is smaller than the die or nut, the tap will turn so hard it will probably break.

Reamers.

Fig. 9: Are used a great deal in auto work as they enable one to enlarge a hole to any desired size (in thin material) without having to resort to any particular size drill. Simply drill a small hole and ream it out to size. Tapered reamers can be had, that come to a sharp point. The one shown in fig. 9 is the blunt type. Note—don't confuse a taper reamer with a taper shank reamer. See chart 287, "Reaming a Hole."

Fig. 9.—A taper reamer.

†TABLE NO. 106.

Drills from No. 80 to 1½ inch size. D. E.—means decimal equivalent. For instance, a number 1 drill is .227 (two hundred and twenty-seven thousandths of an inch diameter).

Size drill	D. E.	Size drill	D. E.	Size drill	D. E.	Size drill	D. E.	Size drill	D. E.

Shields Mechanics Guide Hand Book.

CHART NO. 286-A—Drills. Straight and Taper Shanks. How Marked for Sizes. Reamers.

*See chart 285-B for size drills to use for U. S. and S. A. E. taps.

*See page 616 for a drill and lathe chuck. †This table is size of drill rods, see above, "comparison of table 106 and table 100," page 703.

Results of improperly ground drills: Fig. 5, unequal lip angle; fig. 6, unequal lip length; fig. 7, both lip angle and length unequal.

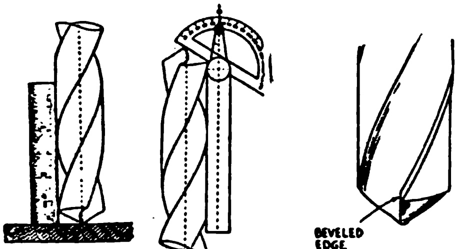

Fig. 9—Method of measuring cutting lip length

Fig. 10—Measuring lip angles

Fig. 11—Method of beveling cutting lip to cut thin or hard material

See page 541, how to read angles in degrees.

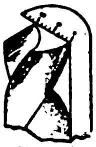

FIG. 10 A

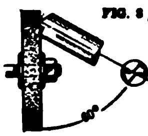

FIG. 8 A

How to Sharpen Drills.

Few mechanics know how to sharpen a drill or how to tell when it is properly sharpened. Four factors are essential. They are:

1–Both cutting lips should have the same angle to the axis; otherwise the cutting will all be done by one lip and the drill will drill oversize. (see fig. 5.)

2–Both cutting lips should be exactly the same length. Otherwise it will throw the point of the drill off-center, causing the drill to cut oversize. (see fig. 6.)

3–Proper clearance back of the cutting edge. Insufficient clearance causes the drill to drag, cut hard and get dull quickly.

4–The angle of the lips should be about 60° each, per fig. 10.

*To Sharpen.

5–Hold the drill lightly against the wheel, as shown in fig. 8A, with the cutting lip on the wheel. Wheels for drill grinding should be fairly soft and open so they will not clog or burn. The drill should be pressed lightly against the wheel and carefully watched to see that it is not burned and the temper drawn. Watch the surface from which the grinding wheel leaves, as the heat is concentrated there. (see pages 696 and 711 for tempering drills and small tools.)

6–Twist the drill and at the same time throw the right hand down in order to grind the proper clearance.

7–Check the length of the cutting lip, as shown in fig. 9.

8–Check the angles of the cutting lips, as shown in fig. 10 and 10A when sharpening it. The best cutting angle is 60 degrees.

Drilling.

9–Brass or thin sheet metal may be more readily drilled if the cutting lips are beveled, as shown in fig. 11. This prevents the drill from digging in and catching.

10–Always clamp or hold the work being drilled to prevent drill catching and breaking, and place a block of wood under the work.

11–In starting to drill use moderate speed, gradually increasing until the best cutting speed is obtained.

12–When drilling small holes, speed the drill up and go carefully when the drill is breaking through the work. This is the point where the drill usually catches and breaks.

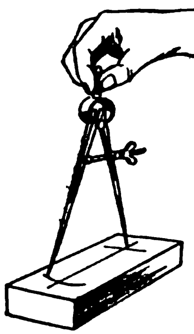
13–When drilling large holes, say ⅝ in. to ¾ in. dia., it is better to drill a small hole first.

14–It is advisable to always make a center punch mark in metal to be drilled.

15–Case hardened steel must first be softened until an even red heat is reached, and re-hardened again.

16–The following are the cutting compounds for the various metals: Hard steel—turpentine, kerosene; soft steel—lard oil, machine oil; brass—soda water, if anything; aluminum—kerosene; cast iron—none. An air blast is a very good cooling medium for cast-iron drilling.

17–If the drill chips out at the cutting edge there is too much feed, or the drill has been ground with too much clearance. A split up the web is caused by the same improper grinding.

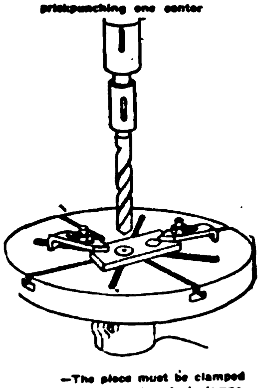


Accurately mark off the center distances with a pair of steel dividers, after first lightly prickpunching one center

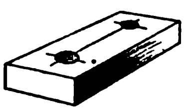
Laying Out Work For Drilling.

The easiest way to lay off work for drilling, etc., on iron or steel is to cover it with a coating of chalk, which permits the lines scribed on the surface with a steel pointed instrument so as to be readily seen.

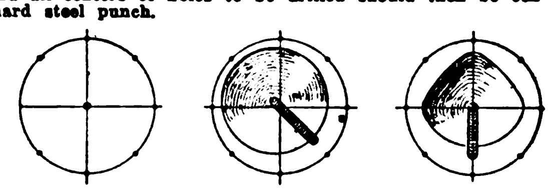
All lines showing the size, location of holes, etc., are scribed out on the metal, previously chalked over, as aforementioned, or if on wood, simply by a hard pencil, and all centers of holes to be drilled should then be center punched by a hard steel punch.



—The piece must be clamped to the drill table by steel clamps. Otherwise the drill will wander, destroying the accuracy of the hole



The finished piece, with the center lines scribed



Left—The piece prepared and ready for drilling. The prick punch marks should be made carefully and lightly. —Middle—The groove should be made the depth that it is desired to draw the drill, and on the side that the drill is to be drawn. —Right—A triangular hole may be corrected in the manner illustrated

A diamond point should be used in "drawing" the drill.

Fig. 8. When drilling a piece of thick metal and drill has a tendency to bore crooked or off the center, it can be re-centered again by cutting a groove with a diamond point chisel on the side towards which you wish to draw the drill, as here shown.

CHART NO. 286-B—Drills and Drilling. Correct and Incorrect Cutting Lip for Drilling. Us[e] of Spring Dividers for Laying Out Work. Re-Centering a Drill. (Motor World and Electrical E[x]perimenter.) See page 708 for drill sizes for U. S. & S. A. E. Standard thread. *See page 615, drill grinde[r]

How To File.

First, select the file suited for the work—see page 613.

Second, the vise jaws should be about 42 in. from the floor.

There are three general methods of using a file; "cross filing," "draw filing" and "revolving filing."

Cross filing: Fig. 1 represents the position of the file when used for filing flat surfaces. The file is grasped firmly but not tightly. Far end of the file may be grasped with the left hand, but not in such a way as to assist the left hand in drawing the file forward. The right hand will push it forward, and the left hand will regulate the pressure desired.

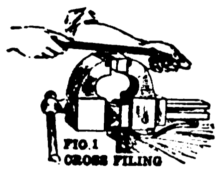


FIG. 1 CROSS FILING

If the pressure of the hand be equal through the stroke, it will be greatest on the corner nearest the workman at the commencement, and on the other corner at the end of the stroke—due to the leverage—and will tend to form a curved surface by imparting a slight rocking action to the file.

Therefore the pressure must be greatest on the left hand at the beginning of the stroke, and as the file crosses the work, must be gradually diminished on the left hand and at the same time increased on the right hand.

Notwithstanding this, it is impossible to file truly flat. If the work be examined with a straight edge (see fig. 5, page 643), it will be found higher in the middle.

Draw filing: To reduce this high part, recourse must be had to draw filing, fig. 2, which is the method used for filing bearing caps, which must be filed even or they will not fit up snug against the opposite member. The file is held at both ends and is operated over the work at right angles to the length of the file. In this position the cutting stroke can occur on the forward or the return stroke or both. An even pressure on each end of the file is necessary, and if this is done, there will be little danger of filing one side more than the other and the oscillation which is certain in cross filing is done away with mostly in this method.

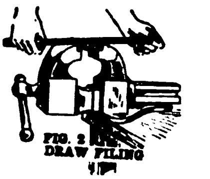

FIG. 2 DRAW FILING

Revolving filing: Is filing done on work in a lathe, chuck or in some cases while in a drill press. Because of the work revolving at a greater rate of speed than the file moves in bench filing, the strokes are less frequent, but should continue through the length of the file, thereby bringing all the cutting edges into service. Hold file in same manner as cross filing in the vise. Do not exert a great pressure as in cross filing or draw filing. Special "machine files" should be used where considerable of this work is done.

**Reaming.

See fig. 9, page 706 and fig. 67, page 792 for illustration and explanation of a reamer and some of the purposes for which it is used.

For instance, if a steering pin hole is worn out of round, per fig. 22, if new parts are not at hand, use a reamer to enlarge the hole to $\frac{1}{32}$ or $\frac{1}{16}$" oversize, then turn a new pin to fit this size, or fit a bronze bushing in the oversize hole with a hole in it to fit the pin (see also, page 792).

Fig. 22—Worn steering pin and rod.

*Cutting a Key-Way.

Key-way cutting with a chisel is an art that requires skill. There are many men who can cut a key-way nearly as well as can be done by a machine, not so the amateur. The first thing to do is to mark out on the shaft the key-way required, with a line to show the center. It is best to drill a series of holes in the shaft to the depth of the bottom of the proposed key-way with a flat bottom drill. The holes should not be in actual contact, if they were so the drill would not bore straight. Then with a narrow cape chisel, chip away the intervening spaces and file with a small blunt square file. Allow the file to work up to the ends of the key-way. The key must be of steel, fitted to bed on the bottom of the key-way and tight at the sides. Keys of different sizes (in the rough) can be bought at tool shops. The key and key-way must be slightly tapered. The key-way will be found shallowest in the middle; this must be worked down, using the edge of a flat file.

Keys.

Woodruff-Keys.

There are three kinds of keys used on shafts; the square key, round and the half disk type, called the Woodruff.

The Woodruff key is used more on automobile work. They are the easiest to remove and apply, but when fitted, the shaft must be milled on a milling machine to take this key. (see fig. 26, page 709).

The round key is seldom used because it is difficult to remove. If, however, a quick job is desired it is the quickest, as a hole can be drilled and the round key hammered in (not advised except on temporary work.)

The square key if applied properly can easily be removed.

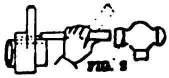
CHART NO. 287—How To File. Reaming a Hole. Keys.

*Keyways on automobile work are seldom cut by hand but are milled on a milling machine, or by a special key-way cutting machine. This explanation is given as a matter of information. **See pages 654, 609, explaining how a cylinder is reamed.

A Drift.

Is used for many purposes. In this instance it is used with square keys.

If the shaft projects from the boss, a drift should be used to prevent damaging the key-way by the blows of the hammer. The drift (fig. 2) is a steel tool with a hardened nose. They are sometimes curved (note the dotted lines), as in many cases it is impossible to get a straight blow at a key. Care should be taken not to burr up the end of the key. A piece of heavy copper held over the end of the key by an assistant will prevent this.



Woodruff Key-Ways.

As stated on page 708, the key-way for a Woodruff key must be milled.

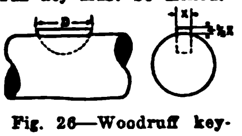


Fig. 26—Woodruff key-way

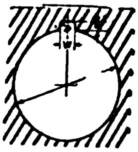
Fig. 26 shows a shaft that has been milled for a Woodruff key, with key inserted. "X" equals the thickness of key. The key should project above the shaft one-half its thickness.



Standard key-ways for pulleys and shafts; table 107 shows the recognized standard for the depth and width of key-way in pulleys. The same formula of course may be used for the depth and width of key-way in shaft.

Table 107.

Diameter (D) of Hole	Width (W) of Keyway	Depth (H) of Keyway	Radius (R)
3-8" to 9-16"	3-32"	3-64"	
5-8 to 7-8	1-8	1-16	.030
15-16 to 1 1-8	5-32	5-64	.035
1 3-16 to 1 3-8	3-16	3-32	.040
1 7-16 to 1 3-4"	1-4	1-8	.050
1 13-16 to 2"	5-16	5-32	.060
2 1-16 to 2 1-2	3-8	3-16	.060
2 9-16 to 3	7-16	3-16	.060

A list of the standard sizes of key-ways both for pulleys and shaft are given.

The radius (R) referred to, refers to the round corners on key.

To Remove Tight Stud.

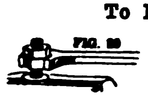


Fig. 20: A method of removing a tight stud is to use two nuts and lock them, keeping wrench on lower nut.

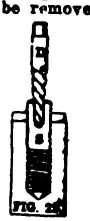
Removing a Broken Stud.

Fig. 22: A broken stud or screw (S) can best be removed by a special left hand drill (D) called the "Ezy-out," mfgd. by Cleveland Twist Drill Co., Cleveland, O.



Other methods are — pour kerosene around the stud to soak into the threads. If a piece of the broken stud stands above—the broken part may be removed with a chisel and hammer—not a sharp chisel, however. A diamond point chisel is best. If it will not move, then drill it out, using a drill well under size of thread. The hole should then be cleaned out with a tap, same size as thread. If in case of a hardened set screw which is broken, then use a blow torch and heat. Another method—if broken part projects; saw a slot and use screw driver.

Over-Size Stud In Worn Bolt Hole.

Use an over-size stud which will make a tight fit in top of cylinder stud bolt holes, then, either file, bore or ream hole out in cylinder head so it will take the over-size stud you are to use. For instance, if a 5/16 inch use a 3/8 inch tap and stud bolt. If a 3/8 inch use a 7/16 inch tap and stud bolt. If a 1/2 inch use a 3/4 inch tap and stud bolt. The holes could be drilled out if you have no reamer. Straight reamer would be best. (See Ford Supl.)

To Remove a Tight Nut.

Try heating it if it cannot be budged with a wrench. Try pouring kerosene on the nut and bolt and leave stand for an hour or so. Drill holes in nut and split it with a chisel if it will not come otherwise. This will save the threads of bolt.

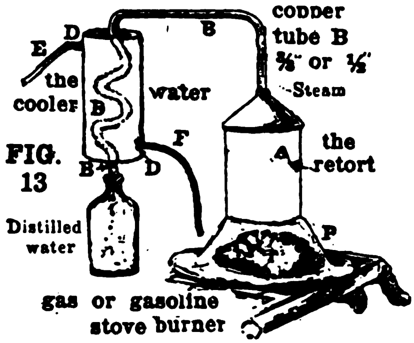
A Stripped Nut—Will Not Grip.

Usually the fine thread nut is the one which causes this trouble. A method that may be adopted is to reline the nut uniformly with soft solder and then give it a start on the bolt, and by working it down the thread a little at a time, cut a new thread inside the nut.

The soldering part of the operation is simple enough, the nut being fastened to a piece of iron wire, dipped in the killed spirits, and then held in the blow-lamp till hot enough to melt the solder. The same process reversed would apply equally well to a stripped bolt and nut used to cut a new thread on it.

Home Made Still For Battery Use.

Fig. 13–A pan (P) with bottom cut out is turned up side down and placed over a gas burner. The retort, A, which can be an aluminum pail, is mounted on the opening in pan. An annealed copper tube (B) is soldered into a cover over the pail. Leave small opening for steam to escape as it is not necessary to boil the water in the pail.



Another receptacle, the cooler, should be suspended at any convenient place or attached to the wall. The copper tube (B), bent as shown, or coiled, which is better, is run through the cooler with projection, to permit a bottle to catch the drippings or the distilled water.

A plug (D) is soldered at bottom and another at top, to which is attached a 3/8" hose (E), which is connected to a water faucet. Hose (F) leads to sink or drain. No pressure is necessary, just sufficient water is required to flow from E through cooler, around tube B, and out F, to cool the tube B.

Regular hydrant water is heated in retort (A) which passes in light steam through tube (B) and is cooled as it passes through (B) in the cooler, thus condensing into distilled water which is caught in bottle. (Motor Age.)

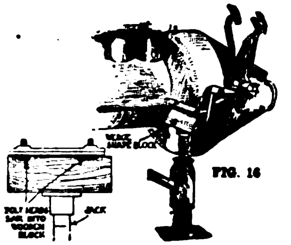


Fig. 16. The four bolts on the front of the Ford transmission can be replaced by one man working alone, by inserting the bolts from under the car, laying a block of wood on top of a jack and lifting the jack till the heads of the bolts are pressed into the wood. This keeps the bolts in place and prevents them from turning while the nuts are put on.

Fig. 17. When the oil pipe T, page 197, of a Ford engine is clogged, remove the radiator and take off the front gear plate. The cam gear is then removed with a puller. This will expose the end of pipe and an air hose is connected to it and air turned on, blowing the clog out. This saves tearing the engine down. If pipe is clogged, gears will be noisy.

CHART NO. 287-A—A Drift. Woodruff Keys and Keyways. Removing Broken Studs and Tight Nuts. Miscellaneous.

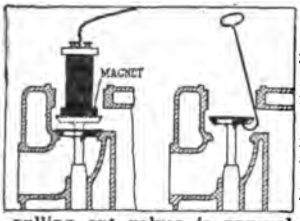

Fig. 1.—A magnetic valve lifter: Magnets have been used many times for picking up all sorts of iron and steel parts, but their use for pulling out valves is unusual. The magnet shown is approximately ¾x3 in. and is capable of exerting a pull of about 7 lbs., and will pull a valve out after springs have been removed.

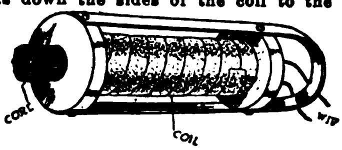
A simple tool which will be found of assistance for removing valves that stick badly but may be raised a slight amount consists of a hook of Bessemer steel wire ⅛ in. in diameter.

Construction of the magnetic valve lifter: An old make and break spark coil forms the basis of the device. The core is made of a bundle of coarse iron wires. The outside of the coil is covered with tape and has a handle consisting of a strip of brass which extends down the sides of the coil to the end.



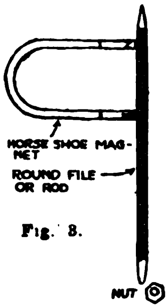


Fig. 3.

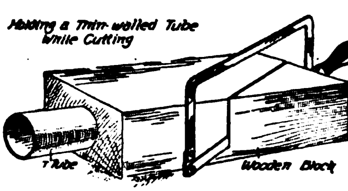
Fig. 3.—Another magnetic lifter — which is useful for removing a nut which may have fallen into cylinder or other inaccessible place is shown in illustration. Simply touching the file with the magnet makes a magnet out of the file (a long rod may also be used instead.)

Fig. 4—Method for sawing through tubing. Consists of a wooden block with a drilled hole to receive the tube. (from Newsabout Fords.)



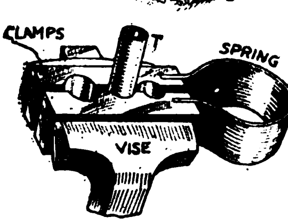


Fig. 5.

Fig. 5—Vise clamps for working with tubing. Note spring tension which keeps clamps in vise when jaws are opened.

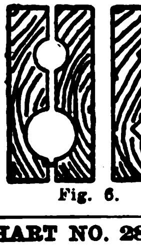

Fig. 6.

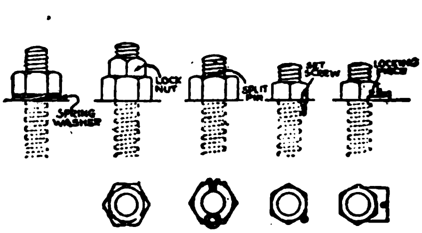
Fig. 6.—Vise clamps made of wood, ½ inch sheet copper and sometimes sheet lead. Are useful and necessary where material is to be clamped in vise, which would mar its surface otherwise.

When vise clamps are made of sheet copper or lead—use ⅛ inch thick—cut to size of vise jaws and bend over top of jaws to support them in place.

Wooden clamps made of hard wood with holes bored through and then sawn across, about ¼-inch or more being cut away; or they can be cut to a V. These latter will take bars or pipes of various sizes without injury.



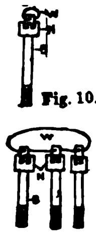


Fig. 10.

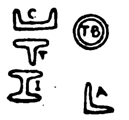
Fig. 9—To prevent nuts from coming off, various locking devices are employed. First one to the left is the well known and most used lock washer. The next one is used a great deal also, that of using 2 nuts. By holding the top one and backing off the lower one slightly, the nuts are securely locked. The next one is also used a great deal in connection with castellated nuts. The other two methods are used extensively by the Navy department (absolutely sure, but expensive.) The lower cuts show a plan view of the various locking devices directly above.

Fig. 10—A stud locking method: It sometimes happens that after securely locking the nut on a stud, the stud unscrews itself at the other end and is lost. When wired as shown in lower cut, this is prevented.

Fig. 11—You have often heard of I-beam front axles and pressed channel steel frames, channel iron, T-head, etc.



C—End view of a channel section.
T—End view of a T section.
I—End view of an I-beam.
A—End view of an angle iron.
TB—End view of a tubular section.

Note—Mostly spoken of as "section"; meaning cross-section or view from end after being cut in two.

***Fig. 17—A spark plug and lamp testing outfit** illustrated below is handy for carrying from one part of the shop to another, for testing on different cars. Several dry cells are placed in a long, narrow box, and connected through a double-throw switch to the testing terminals. One side of the switch throws the two types of lamp sockets (single and double contact, see page 433) into the circuit, and the other side connects the batteries through the spark coil to the plug testing rests. This unit is compact enough to be taken directly to the job.—(Motor World).

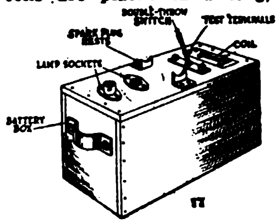


Fig. 64—A foreman's desk: System is essential in the repair-shop, but because it is system does not necessarily require an elaborate equipment. An old packing box may be made into a foreman's desk, and a few strips of wood and tin may be used to construct a workmen's time and work card filing rack. The blank cards are always available, and clean. Any of the workmen's cards may be seen at a glance, and are in order. A clock should be hung near at hand, so that the men will not have to guess at the time—(Motor World).

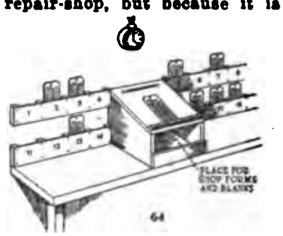

CHART NO. 288—Miscellaneous Shop Hints.

*See pages 418 and 424, for other Electrical Testing Outfits, also 864-H, I, J and K.

High speed steel, usually, should be heated until the tip of the tool starts to melt, and then plunged in oil, or buried in common salt until thoroughly cool. **High carbon steel** gives the best results when heated to dull red and plunged in oil. (See page 695.)

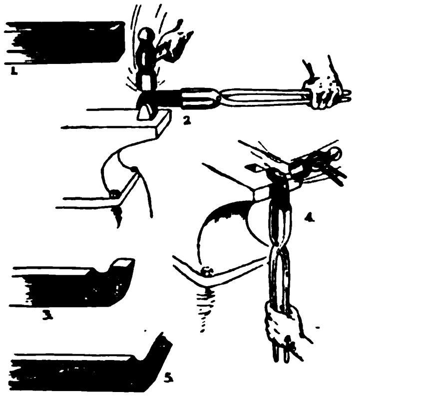

Fig. 2. Steps in making a lathe tool. The work should be done during one heat.

Only the tool point proper should be heated to the plunging temperature, the heat applied slowly at first and then the blast turned on and the point heated to the required plunging temperature.

The tool should be plunged into the oil when the heat is increasing, and at the instant the point reaches the plunging temperature—dull red—in the case of carbon steel; fusing in the case of high speed steel. This is particularly necessary with high carbon steels, as heating the steel white hot, allowing it to cool to dull red and then plunging it in oil will make a poor tool.

High speed steels, after hardening and grinding, are ready for use. Carbon steel tools, however, **must be tempered.** This may be done in two ways, the best being to plunge only the point of tool in oil after heating to dull red, thus leaving some heat in the heel of the tool.

When the point is black, remove the tool and rub the cutting edge with emery paper mounted on a stick. Watch the point closely and as the heat is driven from the heel to the point, the color of the surface being polished will turn light straw, dark straw and blue.

When the point of the tool is straw color, plunge the whole tool in oil and cool it entirely. The other method of tempering is to cool the tool after the first heating, polish the point, slowly heat it again until straw color, and then plunge it.

Almost any grinding wheel may be used for grinding the tool, but care must be taken not to draw the temper, or burn the tool. The tool should be held lightly against the wheel and frequently cooled in water. Grind the tools to the shape desired, following closely as possible those illustrated. Finish the cutting edges with an oil stone.

Fig. 3 shows a tool bit holder and standard set of **high-speed tools.** These are excellent for repair-shop purposes, though expensive. The shapes illustrated will cover a great variety of work, and the tool should be changed to suit the work, rather than regrinding the tool each time. (Motor World.)

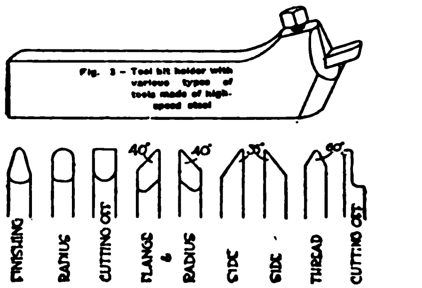

Fig. 3 – Tool bit holder with various types of tools made of high-speed steel

How to Solder.

A soldering copper (fig. 2) is a wedge-shaped block of copper, fitted in an iron fork with a wooden handle. To use, it is placed in a clear fire, or gas or blow pipe torch (fig. 1) burner till it is hot enough to use.

Fig. 2—A soldering iron also called soldering copper.

If the copper is a new one, it must be tinned. When hot, file off the scale on both sides and ends for a quarter of an inch from the tip, so that the metal be clean and bright, dip the nose in the soldering fluid for a second, and then apply it to the stick of solder. A globule will melt off on to a piece of dry brick or tinplate which must be ready to receive it. Rub the nose of the copper in this solder, which will adhere to it as quicksilver does to zinc. The copper can then be used. Copper is used because copper readily absorbs heat and will retain it longer and give it off again rapidly.

The soldering copper must not be allowed to get red hot, as the tin will be burnt off and the tinning process must be repeated. The reader should practice soldering at leisure.

In soldering two parts together, it is necessary that the contact surfaces be perfectly clean. A clean file, scraper, emery cloth or a little acid is generally used in cleaning the surfaces. Sometimes, especially in old work, the emery cloth will not get a clean surface. A dark spot may be a depression; the file must then be used.

If work to be cleaned is greasy, then clean it with hot water and soda.

After cleaning, the surface to be soldered should be warmed, and swabbed with prepared acid; that is, muriatic acid which has been prepared by dissolving in it as much zinc as it will hold.

The flux or acid, generally used may be prepared in the following manner: To ¼ pint of muriatic acid, add scraps of zinc, until the acid ceases to bubble and a few small pieces of the metal remain. Let this stand for a day, then carefully pour off the clear liquid, or filter it through a piece of blotting paper. Add to this a teaspoonful of salammoniac, and when dissolved the solution is ready for use.

A solution of salammoniac and borax also makes a good flux for soldering copper and brass.

Aluminum and cast iron can also be soldered, with a special flux. See page 695 and foot note page 712, 713, also write L. B. Allen Co., Chicago.

Soldering Pointers.

The melting point of soldering material must be lower than article being soldered (see page 539, for melting points of different metals).

Hard soldering or brazing is a term used when the soldering mixture is composed largely of copper, brass, or silver. Use borax for flux. Hard soldering is best, where material will stand intense heat.

Soft soldering is the ordinary half and half (½ lead and ½ tin.) . Plumbers solder has 2 parts lead to 1 of tin, and is therefore still softer than half and half, due to working on lead pipe. **See pages 715, 789 for solder for radiator repairing, known as "50-50" solder.**

Sweating is a term used where the solder is applied to a surface to be soldered and then the hot iron held on it until it "sweats" or runs in.

For electrical work use resin or a soldering paste, as acid sets up resistance in joint.

After an iron has been cleaned and heated and then rubbed on a piece of "fluorite" the tin or solder will spread readily thereon.

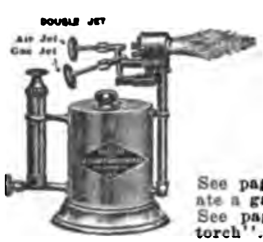

Fig. 1—A Blow Torch. Very useful around any shop

Fig. 3-The "Baby" Torch for light work. Can be carried in the tool box. No air needed.

See page 635; "How to operate a gasoline blow pipe torch." See page 712 for a "brazing torch".

A blow pipe torch, fig. 1 is used most, to heat the soldering iron and the operation of same is explained on page 735. **See page 696, for a gas heater,** which is also suitable. Above torch is a "double-jet" type. **See page 735 for "single jet".**

CHART NO. 289—Lathe Tools (see also, page 616). **How to Solder.** (See also, page 695, 714, 715.)
For radiator work use wire solder with an acid flux core—see page 715.

Fig. 1—Preparing to join two pieces of pipe and method of wiping a joint.

Wiping a Joint.

Joining two pieces of lead pipe—called "wiping a joint." The pipe is first cleaned and prepared, by spreading one pipe as at (A) and pointing the other and ends slipped together, · shown. The solder is melted in a ladle and poured around the joint. A pad of canvas or elvet is held in the hand under the pipe, as shown, the surface of this being well greased with tallow. It need not be more than three or four inches square and about one-quarter inch thick, and the bottom layer may be of asbestos sheet so that there will be no possibility of the molten metal burning through and injuring the hand of the operator.

As the molten solder is poured on the pad, it is wiped around the joint until it is heaped up all around the point of junction, the amount of metal used depending upon the size of the pipe or tubing joined. As the metal is applied and wiped smooth with the pad before it has a chance to harden, the finished joint has a neat appearance. Note—Rub the pipe on each side of the joint with a tallow candle and the metal will not adhere where it is not wanted.

While copper or brass pipe may be joined without difficulty by ordinary methods of soldering or brasing, the wipe method is about the only practical way to couple lead tubing.

Gasoline Feed Line Repair.

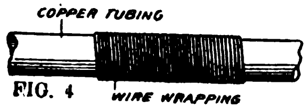

FIG. 4

A broken gasoline feed line may be quickly repaired by scraping the tube near the break, and winding it for 1 in. each side with clean copper wire. The wire should then be heated, covered with soldering flux, and sweated together with solder. A solid sleeve is thus formed that makes the pipe stronger than originally.

Gasoline pipes sometimes get loose in the sockets of the unions. This is due to bad fitting, and shows there is not sufficient elasticity in the pipe; it is too rigidly held. The screwing up of the union strains the pipe and the vibration on the road causes the pipe to give way at its weakest point, namely, the soldered joint. If the pipe gets loose more than once, it shows there is something wrong. A longer pipe should be put in, having a U bend in it or a complete circle to give elasticity. The U bend or circle should lie horizontally, with a drop towards the carburetor; otherwise there may be what is called an air-lock, in the pipe, and the gasoline will not pass through. (see page 192, for principle.)

If the carburetor float leaks, (if of metal) it can be repaired with solder. Sometimes it is difficult to find the leak, for one method of locating it see page 167.

Brazing a Flange.

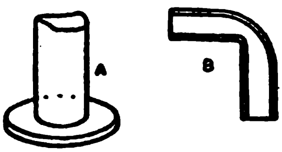

Fig. 2.

If it is desired to braze a flange on to a pipe, the flange is placed on the pipe and the pipe expanded by hammering till it is a tight fit. This is necessary, as it may shift its position in the act of brazing. The flange and pipe (A fig. 2) are put in a clear fire in the forge. Then as it gets hot the spelter, with borax, is sprinkled round the joint, which melts and finds its way into the space between the pipe and the flange. If the reader has a gas or gasoline blow pipe it will make the work easier, as the heat can be directed where required from above. When cool the superfluous brass is filed off. In many cases it is impossible to keep the two pieces of metal in the correct places in the forge, therefore a pin or rivet must be put in, so that they cannot shift, see page 697.

For tube bending see next page.

Brazing Torch.

***A gasoline brazing torch,** for brazing, pre-heating and general work. Principle of operation is similar to that explained on page 785 of a blow pipe torch, except tank and burner (M) are larger. 75 lbs. of air is put into tank by hand pump (P). The tank is a 10 gallon capacity.

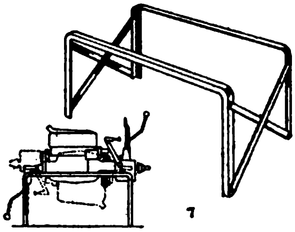

Fig. 7 — Another engine stand: This is a simple engine stand that will take almost any engine. It is 2 inch angle iron, bent into a U-form and fastened together by cross braces. The engine side arms rest directly on the stand, but a cross bar must usually be fitted under the front of the engine to hold it in place. This stand may also be used for rear axle and gearbox work—also see pages 605 and 648.

A Pocketed Valve.

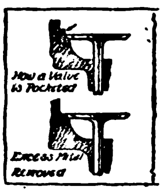

Fig. 8—Remedying a pocketed valve: When the engine begins to lose compression, one of the first things to be looked at are the valves. If the exhaust valves have become pitted, they must be ground in with emery and oil. This process, while it furnishes a ready remedy, when often repeated, will take away a portion of the valve seat. Thus the valve will be lowered and lowered, until finally it is "pôcketed," and much power is lost because the valve does not open soon enough, although the timing might be correct. This difficulty may be overcome by cutting away the excess metal, as shown in illustration, thus restoring the valve to normal conditions. (Newsabout Fords.)

CHART NO. 290—Wiping a Joint. Brazing a Flange. A Home Made Crane. Miscellaneous.

*Clayton and Lambert, Detroit, Mich., manufacture brazing outfits. Also Imperial Brass Co., Chicago. Ill.

See page 696 for gas heater. See also, page 735 for the method of operating a gasoline torch.

To solder cast iron: Clean parts with file until bright, also use muriatic acid. Wash the acid off with water. Then use a hot soldering iron and soldering acid (muriatic acid cut with zinc, page 711) so as to clean pores of iron where to be soldered. Work must be brought up to the heating point required to melt solder. When work is thoroughly cleaned and heated in this manner, cool it with a solution of copper sulphate (copper sulphate dissolved in water). This will give a coppered surface. After coating, wash surplus off, then use soldering acid, the solder and a hot soldering iron and sweat or run the solder in. (Sheet Metal.)

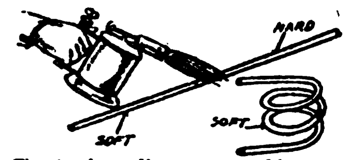

Fig. 4—Annealing copper tubing.

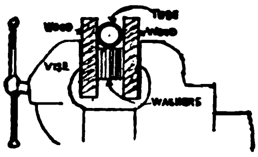

Fig. 5—Form for bending tubing.

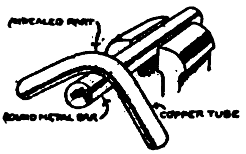

Fig. 6. Fig. 7

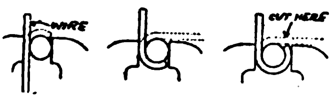

Fig. 11—To bend wire or rods.

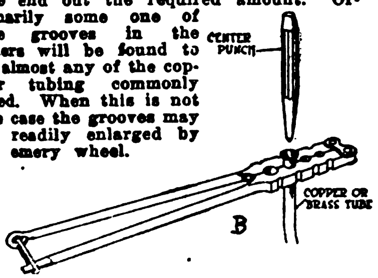
Fig. 12—Flanging copper tubing; Copper tubing may be readily flared for the attachment of unions by the use of a pair of lineman's splicing pliers. The end of the tube to be flanged is caught in the jaw of the pliers and a punch used to press the end out the required amount. Ordinarily some one of the grooves in the pliers will be found to fit almost any of the copper tubing commonly used. When this is not the case the grooves may be readily enlarged by an emery wheel.



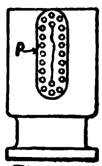


Fig. 16.

Annealing.

Fig. 4—Annealing: The tubing used for gasoline, gas lighting etc., is usually of copper and is usually hard. It is difficult to bend it when hard. The tubing can be softened by heating as shown in fig. 4 (called annealing.) Iron rods and other metals of like nature can also be softened by annealing, see also, page 695.

Bending Metal Tubing.

The problem of bending metal tubing is one that come up quite often in the motor vehicle repair and construction shop. Often when you undertake to bend some of the new kinds of metal tubing you are surprised to have it break, even though the usual precautions may have been taken to prevent a fracture of this nature. Fill the tube with fine sand packed tight, otherwise the walls are very liable to break or they are liable to collapse.

First of all, it is best to determine the character of the composition of the tubes. Many tubes of different manufacturers are made and finished nearly alike and you cannot very well determine what procedure to follow when desiring bends or scrolls in the same. But the file test will quickly remedy this. Or even the point of a cold chisel will do to determine the nature of the metal, then you can work accordingly.

Fig. 5—Bending small tubing: It is well to anneal the tubing first. Then procure several washers, and place side by side until thickness of tubing is obtained. Two wood blocks are placed one on each side and clamped in the vise. The blocks serve as guides. The tubing is then bent by hand over this form.

Fig. 6—Another plan to secure a uniform bend is to employ an outside mandril on the tube. This consists of a closely and tightly-wound spiral of iron wire of about 14 gauge over the tube. This distributes the stresses in the operation of bending, and afterwards it can be unwound. Small bore tubing can be bent by placing a piece of copper wire (a fairly good fit) inside and withdrawing it afterwards. **A piece of string solder well greased can be used and then melted out.**

Fig. 7—To bend small rods and yet leave it circular in form: Drill a hole in a flat piece of iron, fix this in a vise, heat the end of the rod—having previously marked the place where the bend is to be—insert the hot rod in the hole and bend down, using the hammer to ensure a right angle turn, not a curve. The hole must be larger than the rod or the hot end will not enter.

*Repairing a Cracked Cylinder.

Repairing a cracked cylinder: Welding is best, but if this isn't convenient repair with copper as follows:

Fig. 16—A small hole should be drilled at each end of the crack or a little beyond it, for the crack may go further than is visible to the eye. A ¼ inch hole should be drilled and tapped, and a screw inserted and screwed home, and the end filed off flush with the metal. Then a piece of stout sheet copper (P) (not less than 1/12 inch thick) should be cut out, covering the crack extending about ¾ inch all around. This must be bent to fit the cylinder and fixed down with a number of 3/16 inch or ¼ inch screws. Put a piece of canvas smeared with red lead, putty, or thick oil paint under the copper. The patch may leak a little at first, but will probably "take up" in a few days.

Plugging is another plan: A very small crack in a cylinder, probably caused by freezing of contained water, may be mended as follows. Drill a small hole in each end of the crack, and tap it for a small copper plug (fig. 8.) Scrape the surfaces near the crack until the metal is bright. Cover the crack with soft copper filings and melt them in with the blow torch. Use a flux of rosin dissolved in alcohol, or simply drill and thread the hole, if not too large, and screw in a pipe plug tap and saw it off.

Rusting up a small leak in a cylinder; ¼ pound of sal ammoniac to 1 quart of water poured into cylinder and left stand for 48 hours has caused rust enough to form to entirely close a small hole. Be sure and wash out thoroughly. Another remedy is an "iron cement" secured at supply houses. Cider or vinegar will cut rust out of cast iron cylinder water jackets, if left standing for two or three days.

How to Use the Metal Saw.

The fine-toothed blades should be used for iron and steel and the coarser ones for brass and soft metals. For cutting through a brass or steel tube use a fine-toothed blade, as the teeth rip off the coarse ones. Before sawing make a true circumferential line round the tube where the cut is desired; then, by turning the tube round a little between each cut, the latter will be true and square. The broken blades are useful at times for small repairs, as they are readily softened.

Spiral springs; are so readily obtained in a large variety now that it is not often one is at a loss for a particular size of spring. The occasion may arise, (and it is worth keeping in mind) that the hand drill fixed in the vise makes a first-rate winder for small springs, using a piece of round steel rod as a mandril.

CHART NO. 290-A—Annealing. Tube Bending. Repairing a Cracked Cylinder. Flanging Tubing

*There is a spelter called Peters Metalic Filler which can be used in connection with an ordinary gasoline blow pipe torch (or any heat 300° F) for filling up cracked water jackets, cracked cast iron, steel, brass or bronze. This can be used instead of brazing and welding on cracks. Write Aluminum Solder Co., Widener Bldg., Philadelphia, Pa.

Radiator Repairing.

Radiators are divided into two classes: tubular radiators with straight vertical tubes with crimped fins, per fig. 5, page 190, and vertical tubes with horizontal fins per fig. 1 and 5A, page 190. The **cellular type** repair comprises both the tubular type resembling the genuine cellular, per fig. 5B, page 190 and the cellular type per fig. 4 and 4A page 190.

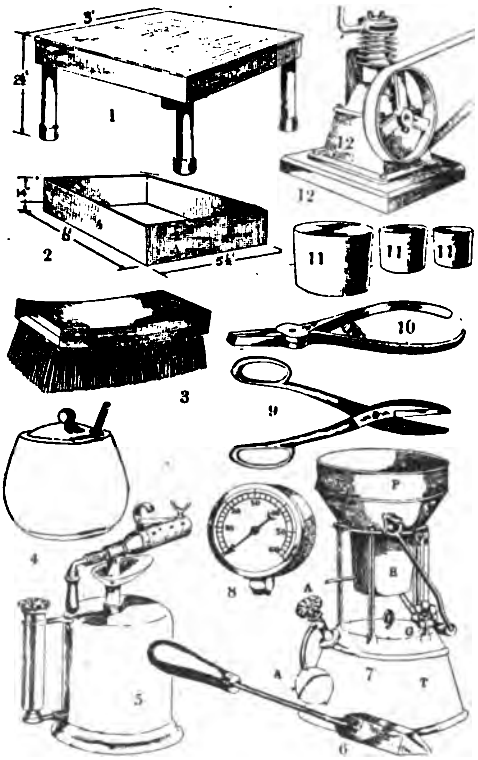
To repair tubular radiators, see pages 715, 789. **To repair cellular radiators,** see page 715.

Equipment.

Equipment necessary for repairing tubular radiators, also for cellular type, consists of the following:

1—**Table as per fig. 1 for assembling or disassembling, or a work bench as per fig. 20.** The latter being designed for Ford radiators. This work bench, fig. 20 includes a table of which dimensions are given on illustration, covered with tin, and racks for turning radiators upside down or otherwise.

2—**A test tank as per fig. 2, or as per fig. 20.** Air pressure is necessary but not over 8 or 9 lbs., see pages 194, 715, 789 for testing.



3—**A compressor** (12) should be provided for the air pressure and a hot-water tank can be used for an air receptacle with a gauge (8) on tank to indicate pressure. This air tank can be used for testing radiators as explained on pages 194, 715, 789. It can also be used for air supply to the torch (fig. 20), in connection with gas. See also, pages 789, 726.

4—**A gasoline fire-pot torch (7) or a gas furnace (fig. 20)** must be provided for heating the soldering irons. See also, page 726.

5—**Two soldering irons** (6) heavy enough to convey sufficient heat to the work. The iron should taper to a flat point as per fig. 6. **Long pointed irons,** per page 789, are also necessary.

6—**Acid** (4), in a stone pot made of commercial muriatic acid cut with zinc, that is, zinc is placed in the acid and left in it until boiling stops. It is used for cleaning parts before soldering and as a flux for soldering.

7—**A blow pipe torch** (5) must be used, but should be of a type which will give a concentrated or flooding flame. It is used for soldering, loosening or removing sections.

8—**A combined gas and air type torch** (fig. 20) is necessary. This torch should throw a fine needle point flame, (see page 726). With such a torch and wire solder, inside core leaks, honey-comb radiators and hard-to-get-at places can be reached, but a torch of this kind must be kept in motion, otherwise part will be burned.

9—**Wire brushes** (3) for cleaning off rust. See also, page 789 for small scrapers.

10—**Metal snips,** or shears (9).

11—**Weaver pliers** for straightening core material, also rods for running through bent tubes.

12—**Rubber plugs** (11), ½" to 4" di. in ¼" sizes for closing openings in radiators when testing with air. See also, page 789.

Soldering Pointers.

Solder: Use "50-50" solder. It can be secured in wire or bar form. See also, page 715, 789.

Soldering iron should be well tinned. When iron becomes so dirty it cannot be cleaned on sal-ammoniac it should be filed and re-tinned. **To tin an iron,** heat it, dip into the acid and rub it on a piece of sal-ammoniac, at the same time holding a bar of solder on the iron and thus coat its surface with the solder. Or, if a pot of molten solder is at hand, dip the iron into it. Never permit iron to become red hot.

To clean old fittings hard to solder, heat the part light red and plunge into raw muriatic acid.

Sweating. When extra strength is desired, seams are "sweated". Sweating is accomplished by first putting the soldering iron (fig. 6) on the seam to be sweated to thoroughly heat the metal. The solder is then flowed onto and between the pieces of metal to be united. Then iron is again laid on the seam, to be sure that the solder flows in as deeply as possible. Iron must be very hot.

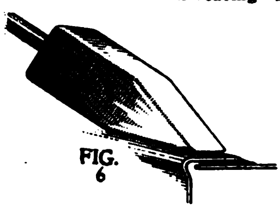


FIG. 6

Fig. 20 Shows a radiator repair outfit designed for Ford radiators. See also, page 789.

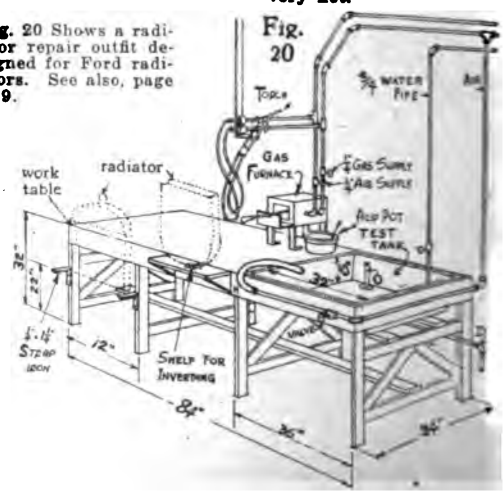

CHART NO. 290B—Radiator Repair Equipment. See also, page 789. **(Motor Age).**

Removing the Core of a Radiator For Repairs.

The core of a radiator is all of the tubes or cells through which the water flows from the upper tank to the lower tank (see fig. 7, page 188). The core is connected into the upper tank and lower tank by projecting into tanks and then soldered. See also, page 789.

The core can be a tubular or cellular type, as shown on page 190. **In the cellular type** (fig. 26), the water flows around the cells and air circulates through the cells, whereas **in the tubular type** core, the water flows **through** the tubes (fig. 25), and air circulates around the tubes.

FIG. 26

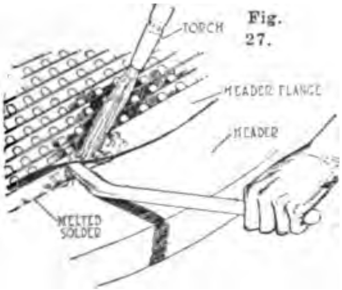

Fig. 27.

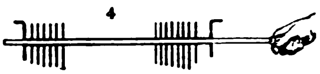
Fig. 26. Cellular and fig. 27 a tubular core.

When a radiator core is damaged badly, the core must be removed. Place radiator on repair bench, face down, and unsolder the lugs which hold shell to body. Then with a torch and a pry bar (fig. 27), unsolder core from bottom tank, then unsolder core from top tank, starting at lower flange or header. The core can then be removed. Don't hold flame in one place too long.

Repairing Tubes.

To straighten damaged tubes when core is removed, use a long steel bar (fig. 4). This will also clean tubes and should be done on all tubes.

4



****When only one or two tubes are damaged, the tube can be cut out of service altogether, for instance, see A, fig. 25.** Make holes at extreme top and bottom of tube and close to header as possible, using a prick punch. Flow solder into the holes liberally and let it set until hard. See A, fig. 25.

Fig. 25.

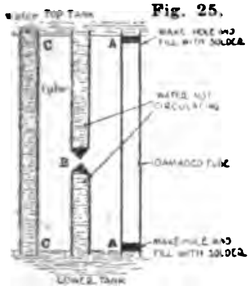


FIG. 21

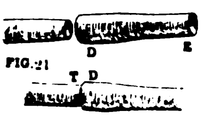

FIG. 22

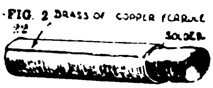

Sometimes tubes are cut out of service by cutting tube and pinching it and soldering, as shown at B, this however, is not good practice, as the water will collect and freeze, in winter.

To splice a tube, see fig. 21. Cut out the damaged part of tube. Select another piece same diameter as piece removed, but slightly longer. Spread one end by reaming with a punch or any tapered tool, and make other end smaller by making a few cuts in it lengthwise, and then compress the end. Fit large end D, over end of tube being repaired and the other end over other part of tube and solder.

Another method, see fig. 22, is to wrap a piece of light brass or copper around the injured part of tube so that the edges of the patch just meet or fail to do so by a slight margin, soldering it.

A Fin Repair.

Where the lateral fins of a tubular radiator (Ford type) have been removed for a repair, a false fin D, may be made as per fig. 29, by folding a ¾" strip of light brass, copper or even sheet iron longitudinally upon itself to make a double strip ⅜" wide. Bridge it across the gap in the fin or fins and then paint the patched place the same color as the rest of the core. See also, page 789.

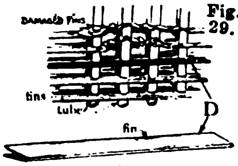

Fig. 29.

Fig. 30.

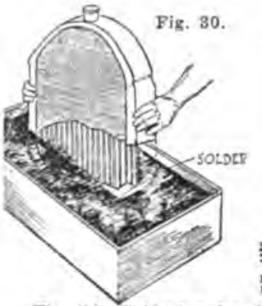

Fig. 31.

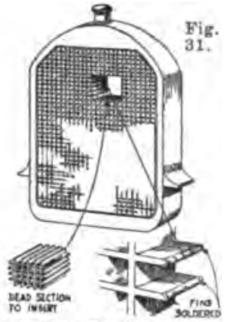

Fig. 30. Soldering by dipping: In large shops the tubular radiator is dipped into a solder bath. The parts to be soldered are thoroughly cleaned and treated with muriatic acid solution, then dipped. The solder naturally will adhere only to the parts that are clean. **The solder** is made of 50 per cent lead and 50 per cent bar tin melted together.

Repairing Cellular Cores.

The cellular core is removed from the tank by melting the solder with a blow pipe torch. As inch by inch is melted away, insert a piece of sheet iron between core and tank so that when flame is removed the solder hardens and core and tank are not reunited.

***Inside leaks** in cellular cores can be soldered with a torch throwing a fine needle flame, being very careful to not burn the light metal up. Squirt acid or soldering flux on the spot with an ordinary oil squirt can. Deposit solder on the spot, using wire solder and the blow torch. Smooth solder over afterward with a small thin iron. A suitable iron for this work may be made from ordinary ¼" iron. See also, pages 789, 726.

To remove a leaky cellular section from core, the leaky section is cut out (fig. 31) and all water passages into all sides are soldered up. After testing, a dummy section is inserted and soldered. The cooling capacity will be reduced slightly.

It is advisable to secure an old radiator core and practice soldering it before attempting a repair.

Solder and Flux.

Cleaning parts to be soldered is most important. This can be done by **scraping** and also by using **muriatic acid** applied to a cloth attached to a wire, if in a close place.

Soldering flux, which is applied after cleaning in order that the solder sticks, is made of cut muriatic acid, per page 711.

Wire solder with acid or flux in the core of the solder is best for radiator work. Write Chicago Solder Co., 218 No. Union Ave., Chicago.

Supplies and tools for soldering—see pages 714, 789, 726.

Leak Preventatives.

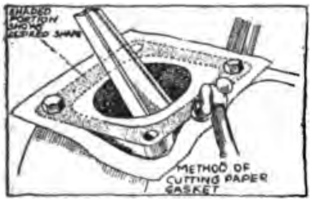
Slight leaks in radiators and even a crack in the water manifold can be stopped by use of some of the radiator cements circulated in the water system. Some of the manufacturers of radiator cements are Woodworth Mfg. Corpn., Niagara Falls, N. Y.; X-Laboratories, 630 Washington St., Boston, Mass.; N. W. Chemical Co., Marietta, O. See also, p. 789.

CHART NO. 290-C—Radiator Repairing—continued. See also, pages 714, 194, 789.

****Not necessary to remove core or tear down radiator for slight repairs.** Simply force the fins to one side an straighten them after the repair. **Before making a repair, it is, of course, necessary to test,** per pages 194, 789 to find out where the leak is and then solder without removing core, if only a slight leak.

*Not necessary to remove core from radiator shell unless there are several leaks or core is damaged.

Cutting Gaskets.



Perhaps one of the first things at bench work a young repairman is taught on entering a shop is that of cutting gaskets.

The gasket between the base of cylinders and the crank case and the cover of gear box, are usually made of paper.

If care is not exercised in removing a cylinder from the crank case, the paper washer or gasket may easily be damaged by part of it adhering to the cylinder and another part to the crank case. Should the gasket by chance be ruined, a new one can easily be made in a few minutes.

Cutting cylinder head gaskets: A sheet of fairly heavy wrapping paper should be obtained and a hole made just large enough to accommodate the piston. The paper is then rested on the crank case and with the aid of a ball-poen hammer tapped all around the edges of the crank case. It is, however, best to first mark the holes for the holding down bolts and inserting the latter to hold the paper in position.

When making the corners and also the holes for the bolts it is best to use the poen or round end of the hammer.

It is not necessary to strike the paper a hard blow, only a series of slight taps being required when it will be found that the gasket will have a n'ece clea. cut edge and conform exactly to the desired shape.

It does not matter much how complicated the shape of the gasket may be for if the above suggestions are followed, making a new one will be comparatively simple.

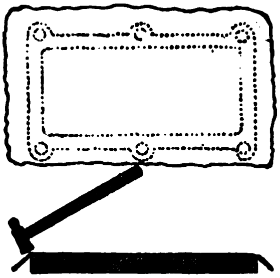


Fig. 2—Cutting a paper gasket for transmission cover.

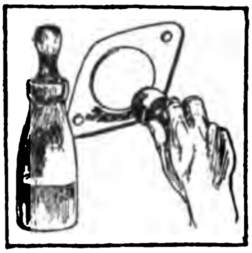
The hardest part of the whole procedure is to keep the paper in place on the crank case, but if the holes for the holdiug-down bolts are first made and then the bolts inserted as shown in the illustration, no difficulty should be experienced.

After the gasket is finished it should be covered on one side with shellac and allowed to dry a short while. Then when the nuts are tightening up a good oil-tight joint results.

Cutting gaskets for gear box cover: The same principle applies.

Be careful in tapping so that the edges will not be broken. Sometimes it is possible to press the paper by hand and make indentation enough to cut the gasket from.

Other gaskets, such as mobolene and asbestos gaskets are made in similar manner, but are usually marked off by pressure of hand or finger, when placed over the part to be fitted, then cut out with a sharp knife. Asbestos gaskets for cylinder heads are sometimes made when nothing else can be had. It is soaked in linseed oil before applying.



A bottle of shellac is needed in every repair shop.

Shellac.

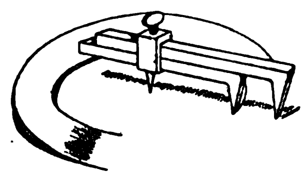
Shellac is an excellent preparation to insure a good tight joint and ought to be used on only one side of a gasket. Shellac dries up, but a good way to handle it is to have a wooden stopper which can be used for applying the shellac as well as acting as a stopper.

When a workman wishes to spread a coat of shellac upon a gear-case cover, or a gasket, he has but to invert the bottle with the stopper in place, then remove the stopper and roll the large end over the surface to be smeared, and a coat of shellac is left in its wake.

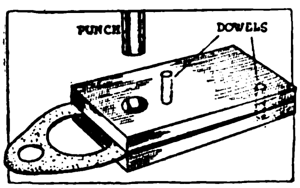
How to mix shellac: Secure an open mouth bottle, fill nearly full of flake shellac and pour in alcohol, and let it dissolve. This will make a very thick solution. To make it thinner put in less flakes of shellac. The flakes can be secured at any drug store.

Using shellac: In replacing detachable cylinder-heads, only the smallest possible amount of shellac should be used and this should be quite thin. If the shellac is heavy and any considerable quantity is used it will squeeze out into globules and the first explosion will blow these into the valve ports, where they will start an accumulation of carbon.

Note—When using shellac on a gasket, use it on but one side. The gasket can then be used over and over again. Otherwise it will be necessary to make a new one each time removed. Common grease is used by many to hold gasket in place until part is placed in position and drawn up.

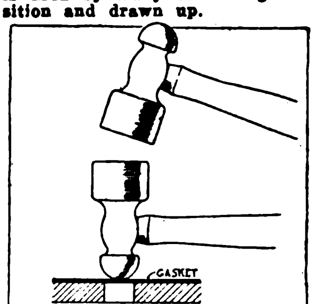


A device for cutting circular gaskets may be made out of two pieces of steel shaped as shown and fitted with a clamp which forms the center. The two cutting members are adjustable, so that practically any size of gasket may be cut.



It is difficult to cut holes in gaskets and not have ragged edges. When there are a great many holes of a given size to be made, it is advisable to construct a die consisting of two plates of metal doweled together and with a hole or series of holes through which the dies may be pushed. The gasket material is slipped between the plates, and then the die is forced through with a hammer

Another method is to file a chiseled edge on short sections of different size iron pipes which can be used as punch cutters.



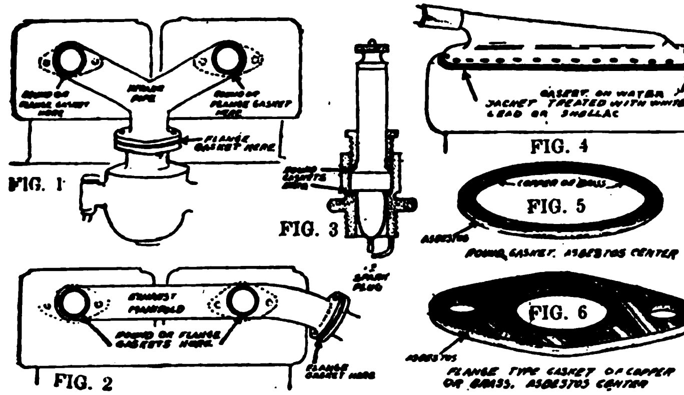
When cutting gaskets from metal and asbestos packing, felt and other materials it is sometimes difficult to cut bolt holes, especially those close to an edge, without damaging the material. A way out of the difficulty is to use two round-headed hammers, placing the round head of one over the hole and striking it with the other.

Packing for Water Pumps and Lubricators.

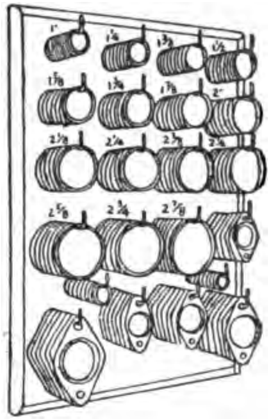
Packing for water pumps and lubricators: For all packing joints nothing has been found better than **asbestos string plentifully** smeared with a mixture of heavy oil and graphite. Candle wicking can also be used if asbestos string is not handy.

Ball bearings for cutting small holes: Ball bearings of various sizes are useful in cutting small holes,. such as for studs, in gaskets. After the gasket is cut to shape by hammering around the edge of the gasket flange, a ball bearing is put over the hole and hammered until the hole is cut in the gasket. This method produces sharply defined edges. In cutting paper gaskets it is advisable to grease the paper first so that it will stick to the surface.

CHART NO. 291—Cutting Gaskets. How to Mix Shellac and How to Use it.



Showing the different places where the round and flange type of gasket are used.



*Gaskets—Different Kinds.

Gaskets are used on the engine and gear-box and other parts of the car. The purpose being to make tight joints. Thin gaskets are preferable to thick ones and should always be used on all joints that come together square. Metal to metal joints are best, but it is next to impossible to make both flanges meet absolutely square. It is for this reason that some sort of flexible material is interposed to make up for the inequalities in material and workmanship.

On the engine, gaskets are used in such places as the gear case cover in front of engine, water plate on cylinders, on the intake and exhaust manifold, spark plugs, etc.

On the gear case, a gasket is usually placed between the cover and gear box to prevent the oil from working out.

The housing cover on differential is sometimes fitted with a gasket, but more generally it is simply given a coat of shellac.

There are several kinds of gaskets; the paper, asbestos, asbestos wire lined, copper and in the absence of copper-asbestos lined gaskets —lead can be used.

The copper or brass gasket for such places as the intake and exhaust manifold are usually made of copper or brass with asbestos interlined. They are made either round or flange shape. Copper gaskets are also used between the water plates or pipes on cylinder. These gaskets can be bought ready made.

Flange shaped copper or brass gaskets are also used between the carburetor and intake pipe. (Lead or leather can be used, also mobolene.)

Asbestos gaskets are made of closely woven, long fibre asbestos yarn and brass wire closely woven and impregnated with a heat and water resisting compound. The red compound on one side sticks to flange when joint is broken. The graphite on the other side allows joint to be easily taken apart. Sold in rolls or in gaskets cut to order. This is used in many places, such as the water plate, but it is usually used where there is a great deal of heat. If sheet asbestos (not wire woven) is used, it ought to be soaked in linseed oil.

Paper gaskets can be used in many places. For instance the plate cover for gear box and between cylinders and crank case. In using paper select a heavy wrapping paper and shellac it well on each side when applying.

Paper of light cardboard weight can also be used for the water plate on cylinders but must have shellac on each side.

Board measures 17x26 ins., has 26 hooks and holds 650 gaskets of the following; sizes:

Round Closed Type Gaskets.
Fig. 5.

25—1 -inch I. D	25—2⅝-inch I. D
25—1⅛-inch I. D	25—2½-inch I. D
25—1¼-inch I. D	25—2⅝-inch I. D
25—1⅜-inch I. D	25—2¾-inch I. D
25—1½-inch I. D	25—2⅞-inch I. D
25—1⅝-inch I. D	25—3 -inch I. D
25—1¾-inch I. D	25—3⅛-inch I. D
25—1⅞-inch I. D	25--A.L.A.M. Size
25—2 -inch I D	25—Metric Size
25—2⅛-inch I. D	
25—2¼-inch I. D	

Exhaust Type Gaskets.
Fig. 6.

25—1⅛-inch C.H	25—1¾-inch C.H
25—1¼-inch C.H	25—2 -inch C.H
25—1½-inch C.H	25—2¼-inch C.H

Note—I. D. means inside diameter and C. H. refers to the type, (copper-covered diamond shape.)

All the above is supplied on the one board. The board is given free with the order for the above lot.

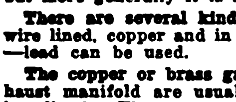
Every repair shop ought to have a well assorted lot of copper or brass gaskets interlined with asbestos. A choice selection in sizes given all placed on a board to hang up in the stock room.

In addition to the type shown in illustration, other types of gaskets are supplied, such as cylinder head gaskets, etc.

Gaskets are also supplied in full sets for the Ford, Overland, Buick and other cars. Also for motorcycles.

Tightening Nuts on Cylinder Heads.

Detachable cylinder heads now are quite generally used, and it is very important in connection with them that they be kept tight against leakage at the joint with the main cylinder casting. A striking loss of power in a certain engine was puzzling until a thorough inspection revealed that some of the head bolts were loose, allowing some of the compression pressure to escape.



There are also many instances of careless tightening of heads and cylinder blocks which have resulted in cracking the casting. This is due to drawing down one bolt or series of bolts too tightly before equalizing the strain by tightening others in another part of casting. The object is to pull the casting down uniformly without any tendency to bend or distort it.

Diagram to the left; cylinder head has fifteen bolts, and the numbers on the diagram indicate the order in which they should be tightened. It will be seen that the center bolts are adjusted first, then the rest are tightened alternately.

To Stop Noises About Car.

When seeking to stop rattling noises about the car attend first to the fenders, then to the brakes, hood fasteners, lamps and finally to doors and springs. As a rule the fenders, doors and springs are the most troublesome source of noises on the average present-day machine.

CHART NO. 292—Gaskets. Tightening Cylinder Head Nuts.—see pages 239 and 607 for Spark Plug Gaskets.

To cut paper on running-boards of new cars: A new car usually has brown paper over the running board and floor boards to protect them in transit. A good way to remove this neatly is to fasten a safety-razor blade in a small block of wood and trim close. No ragged edges will be in evidence.

*Write Stevens Co., 375 Broadway, N. Y., for circular on gaskets, which gives sizes and prices for all leading cars. Mention this book.

††Oxy-Acetylene Welding.

Blow-pipe welding is a very ancient art and was first practiced by the Egyptians. The early process consisted of heating metals of a low melting point by means of a torch, using a crude fuel gas and drawing the necessary oxygen from the air.

The modern process of blow-pipe welding is somewhat similar, but it is applied successfully to the welding of *high melting point metals, as well. This was not possible until oxygen was obtainable on a commercial scale and a fuel gas giving the necessary high flame temperature could be provided in safe, convenient and purified form.

Before this process of welding was invented, when a crank case or an exhaust manifold, gear case, cylinder or other metal part was cracked or broken, it was necessary to get a new part, fully machined, from the factory. This was quite an expensive proposition. With the oxy-acetylene outfit it is possible to repair these at a very slight cost and save those parts which would otherwise be worthless. Steel, iron, aluminum, brass, copper, platinum and other metals can be perfectly united.

There are two types of oxy-acetylene outfits: the **stationary** type and the **portable** type. The parts of the stationary outfit consists of a generator which generates the acetylene gas from carbide, a tank of oxygen and a torch of special design and a special iron table with brick top.

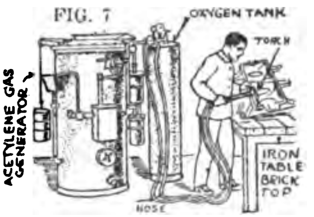


Fig. 1—The stationary oxy-acetylene outfit. Note the iron table with brick top.

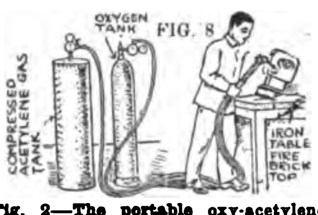

Fig. 2—The portable oxy-acetylene outfit.

The portable outfit consists of the same parts but instead of there being a gas generator, the acetylene gas is compressed into tanks by concerns who make a specialty of this work in all large cities. This type is the one mostly in use in small shops. The portable outfit can be put into a car and carried right to a garage for the work to be done and quite often save dismantling the engine or broken part.

Method of welding. To those who are not familiar as to just how welding operations are performed with this process, it may be said that welds are made by directing the oxy-acetylene flame on the pieces to be welded at the place where they are to be joined, until the metal is molten, and then adding additional metal of the same character, which is provided in the form of wire or sticks of suitable dimensions for the purpose.

An outfit for welding is shown in chart 293.

The oxygen is furnished to customers in portable steel cylinders into which the oxygen is compressed to 1,800 lbs. to the square inch. **To estimate the pressure readings** a gauge is supplied. Take for instance an oxygen cylinder that holds 100 cu. ft. at 120 atmospheres, or 1,800 lbs. pressure approximately, each atmosphere represents ⅚ cu. ft. With a 250 cu. ft. oxygen cylinder, each atmosphere, or 15 lbs. pressure, represents 2.08 cu. ft. of oxygen.

Acetylene is supplied to users in specially constructed steel cylinders of various capacities. The maximum charging pressure is 250 lbs. to the square inch at 70° Fahr. The cylinder contains about ten times its own volume of acetylene for each atmosphere of pressure that is on the gas. The porous substance, such as pumice stone or charcoal which is in the tank, is saturated with a liquid solvent which has the peculiar property of absorbing, or dissolving many times its own volume of acetylene at atmospheric pressure. When pressure is applied, the solvent continues to dissolve acetylene.

Cylinders are, as a rule, charged to 15 atmospheres pressure at 60° Fahr., so they contain 150 times their own volume when charged. Thus a cylinder that would hold 2 cu. ft. of water when empty will hold 300 cu. ft. of acetylene at 225 lbs. pressure, 60° Fahr.

Prest-o-lite acetylene **cylinders for welding are furnished in large **size** cylinders, style "WC," having approximately 100 cu. ft. capacity, and style "WK" approximately 300 cu. ft. capacity. They are made as small as 30 or 40 cu. ft. capacity.

No cylinder should be **exhausted** at a rate greater than ⅐th of its total capacity per hour. Where the needed amount of acetylene per hour exceeds ⅐th of the capacity of one cylinder, connect two, three or even more cylinders so the total capacity is at least seven times their hourly discharge.

It should be borne in mind that the contents are not accurately determined by pressure or gauge readings, which are affected by variations in temperature. The only accurate method is by weight, one pound of gas equaling 14½ cu. ft. Gauge pressures, however, are of great conveni-

*See page 539, giving melting points. ††Also called autogenous welding.

**An instruction book on oxy-acetylene welding can be obtained of A. L. Dyke, Pub., Granite Bldg., St. Louis, Mo.—Price $1.10 prepaid. It treats on carbon burning or decarbonizing, cutting and welding.

ence in estimating roughly how much gas remains in the cylinder. In the case of a 100 cu. ft. cylinder each 15 lbs. of pressure represents 6⅔ cu. ft. of gas (approximately) and in a 300 cu. ft. cylinder each 15 lbs. of pressure represents 20 cu ft. (approximately)—according to temperature.

Application of blow pipe welding—generally known as "autogenous" welding, although the same term could apply to electric welding. Autogenous welding must not be confused with brazing or soldering. Brazing or soldering, is where a joint is made in which a different metal, having certain adhesive qualities, is used as a binder—it adheres but does not "fuse." Oxy-acetylene welding is where pieces of metal are united, or new metal added, as in the case of building up worn parts—welding iron, steel, cast iron, malleable cast iron, aluminum, brass, copper, etc.

Qualifications of an Operator.

A few weeks practice will develop skill necessary to handle ordinary work likely met with in the average shop. Very thin plate work and neat work, will of course require skill and practice.

Welding together of plates over ¼ inch thick should not be attempted on particular work, until operator has demonstrated, by first welding some sample pieces.

The operator must have a fair knowledge of the nature and properties of the metals being welded, the effects of expansion and contraction, the reason for the use of fluxes and filling rods, (see page 721), the proper kind of filling material, how to apply heat without burning the metal, etc., all of which can be learned from books treating on the subject.

With this knowledge and practice the business will be very remunerative.

Parts of Welding Outfit.

Welding outfits and parts are shown on pages 720, 727. The oxy-acetylene welding and cutting outfit can be used for various purposes as follows:

(1) Welding broken frames, gears, shafts, crank cases, engine supports, axle parts, castings, cylinder water jackets, gear-sets, etc.

(2) Cleaning tire vulcanizer molds.

(3) Removing solid tires.

(4) Burning carbon from cylinder, per page 624.

(5) Removal and replacement of terminal straps, plates of storage batteries and other lead parts, per page 471.

The welding blow pipe is shown in fig 1, chart 293: Various size tips are used for different kinds of work.

The acetylene regulator (fig. 2) is connected to the valve of the acetylene cylinder by means of the union nut (M), which must be drawn up tightly.

The oxygen regulator (fig. 3) is connected to the valve on the oxygen cylinder by means of the union nut (AA).

The Welding Flame.

Is obtained gradually, by increasing the regulating screws alternately, until correct welding flame is obtained. The correct oxygen and acetylene working pressures vary slightly for the various sizes of blow pipe tips which are used for different work. All adjustments are made at the regulators while blow pipe is alight.

Flame adjustment—it is absolutely necessary at all times that the welding flame be neutral, that is, that there be no excess of oxygen or acetylene. A correctly adjusted (neutral) flame is shown at B of fig. 4. It will be noted that the inner cone is clear, and well defined. (A) of fig. 4 shows a flame having an excess of acetylene. The inner cone is ragged in appearance. To make such a flame "neutral," the acetylene should be cut down by reducing the pressure either at the regulator or at the blow-pipe, or by increasing the oxygen supply. C of fig. 4 shows an excess of oxygen. The inner cone has a very pale violet color and is shorter than the cone in the neutral flame at B. Proper adjustment, in this case, is accomplished by reducing the oxygen pressure or increasing the acetylene pressure at the regulators or at the blow-pipe.

The temperature of the oxy-acetylene flame is 6,300° Fahr.

The regulation of the welding flame really means the regulation of the white inner cone. This cone should always be as large as possible, provided its outline is sharp and distinct. A long, clear inner cone should always be sought. The gases should be readjusted several times, if necessary, until the desired result is obtained.

When the blow-pipe is first lighted, it is cold. Radiated heat from the molten metal will gradually warm it. This is apt to affect the welding flame slightly. It usually will be found necessary to make readjustment of the gas pressures by means of the oxygen and acetylene needle valve on the blow-pipe after the blow-pipe has been at work for a few minutes.

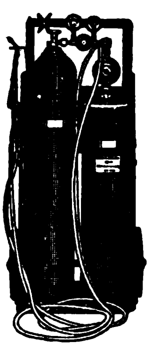
Method and Material for Welding.

***Preheating and re-heating** is sometimes necessary—in order to bring the metal to a uniform heat to insure uniform contraction while cooling. Figs. 17 and 19, show devices for this purpose (chart 293). (See also fig. 5, page 726.)

Filling rods are used to fill in gaps or cracks. Rods or wires are used of various lengths.

Fluxes—some metals do not flow together rapidly when heated (due to oxidation), therefore a suitable flux, in the form of powder is used. It is sprinkled in the weld by dipping the heated filling rod, from time to time into the flux.

The size of blow pipe tip is decided upon before welding. For instance, cast iron requires a larger flame than steel.



The Standard Prest-O-Lite Type H Welding Outfit.

1—cylinder of Prest-O-Lite dissolved Acetylene.
1—cylinder of compressed Oxygen.
1—welding blow-pipe with seven interchangeable welding tips, Nos. 1, 2, 3, 4, 5, 6 and 7. (Fig. 1.)
1—automatic constant pressure acetylene regulator, fitted with inlet and outlet pressure gauges. (Fig. 2.)
1—automatic constant pressure oxygen regulator fitted with inlet and outlet pressure gauges. (Fig. 3.)
2—suitable lengths of rubber hose.
1—set of four hose clamps.
1—box end wrench for needle on Prest-O-Lite dissolved acetylene cylinder valve (T socket).
1—wrench for attaching oxygen regulator.
1—stuffing nut wrench for Prest-O-Lite dissolved acetylene cylinder and for attaching acetylene regulator.
1—box end wrench for welding blow-pipe.
1—box wrench for welding tips.
1—pair special colored lens goggles.

(KK) Union nut on oxygen hose nipple.

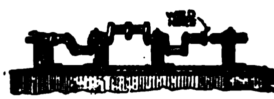

Fig. 13. Example of six-throw crank shaft lined up on "V" blocks and clamped on face plate for welding. The broken sections are shown bevelled to a chisel edge.

Fig. 14. Lower half of aluminum crank case clamped to angle irons to insure true alignment. A patch is shown "tacked" in position ready for welding.

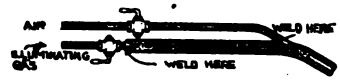

Fig. 17. Construction of air-illuminating gas pre-heating torch. Over all length, approximately 3 feet.

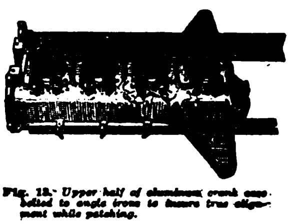

Fig. 15. Upper half of aluminum crank case bolted to angle irons to insure true alignment while patching.

In all welding operations, the parts to be welded should be set in proper alignment before the flame is applied. The work is sometimes found to be out of alignment and the part rendered useless otherwise.

It is always advisable to have on hand a good supply of different size clamps, "V" blocks and mandrels. These are always useful in setting up various jobs. see figs. 13, 14, 15 and 16.

Expansion and contraction—In every case of welding, internal strains are inevitably set up due to expansion when heating and contraction when cooling. When parts being welded form part of a structure and are not free to move during the welding process, the strains produced may cause the metal to crack. This is especially true of cast iron.

If cooling after welding is too rapid or is irregular, a crack is liable to occur. Therefore it is advisable to heat parts before welding (termed pre-heating) and then to heat after welding (termed re-heating.)

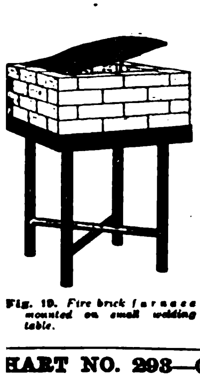

Fig. 19. Fire brick furnace mounted on small welding table.

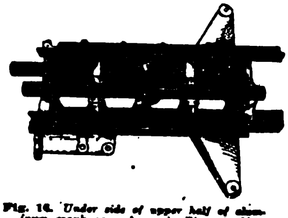

Fig. 16. Under side of upper half of aluminum crank case shown in Fig. 15. Note mandrels clamped in crank and cam-shaft bearings.

[C]HART NO. 293—Oxy-Acetylene Welding. (from Prest-O-Lite Instruction Book.)
[Se]e also page 696 and 472 for illuminating gas torches.

Welding a Cylinder—Importance of Preheating.

Fig. 5, page 726 shows a small furnace for automobile cylinders. After a layer of firebrick has been placed on the table, the cylinder is supported on several bricks, and the walls of the furnace built up around it. Half bricks are used for the second layer from the bottom, so that openings are left for the air supply.

The fuel used should be the best grade of hardwood charcoal obtainable. This burns freely, without smoke or odor, requires no forced draft, and does not injure finished surfaces. It is only necessary to pack it around the piece to be heated, to light it, and let it burn at will. When in use the top of the furnace should be covered with a sheet metal plate. Vent holes should be closed when cooling. (cool slowly.)

Iron and Steels.

Under this heading are included commercial wrought iron and mild or "low carbon" steel.

Practically all of the so-called "**wrought" iron** on the market today is in reality a **mild steel.** For this reason wrought iron and mild steel metals are discussed as one.

"**Low carbon**" or **mild steel** is quite ductile and malleable, but has a lower tensile strength and lower elastic limit than the "high carbon" or hard steels. No close distinction can be made between high and low carbon steels, but in general anything below 25 point carbon (0.25 per cent) may be designated as mild steel, while those containing more than this amount are either half hard or hard.

Most of the steels that the operator will be called upon to weld are mild. There are various special or alloy steels such as vanadium, nickel, chrome, manganese, etc., which will be taken up separately.

Preparation of parts—Mild steel parts are prepared in the manner described in the general instructions. Several methods of preparing various parts to be welded are shown in the accompanying illustrations. see chart 293A, figs. 24 to 41 inclusive.

High carbon or hard steel—weld as per instructions on mild steel or wrought iron, and use a larger blow-pipe tip. For filling use drill rod—a hard steel—this can be tempered, ordinary mild steel cannot. Use cast iron flux. Execute weld rapidly. A slight excess of acetylene may be advantageous.

Cast steel—weld similar to instruction on cast iron. Cast bars of same material or vanadium steel or Norway iron will answer for fillers.

Special steels—such as manganese steel (low carbon). As filler use same material or Norway iron.

Nickel steel (low carbon) same as mild steel, but use nickel steel filling rod.

Vanadium steel (low carbon) probably used most of the various steel alloys. Weld as mild steel—use vanadium steel filler.

Chrome steel—weld as mild steel—use chrome steel filler. Many chrome steels are in the high carbon class and general remarks on "special steels" apply.

Cast Iron.

Is more difficult to weld. Carbon exists in cast iron in different states. In what is called white iron, which is very hard, the carbon is combined with or dissolved in the iron. In the grey iron, which is soft and easy to work, most of the carbon is in a free state in the form of graphite. Since it is generally necessary to machine or file a weld in cast iron, it is indispensable that the line of the weld be constituted of soft grey iron. Thus, in welding cast iron, always remember that too rapid cooling brings about a combination of the carbon and iron, forming hard, brittle white iron; while slow cooling or reheating after the weld is completed keeps the carbon in a free state, resulting in a softer, more workable material.

Preparation of parts—castings, before welding, should be very carefully freed from grease and rust. Cracks in metal over 3/16 inch thick must always be beveled before welding. When beveling cast iron it is not necessary that the groove penetrate through the entire thickness of the metal. It will be found best to leave about 1/8 inch of the thickness unbeveled as shown in fig. 38, chart 293A. When the metal is over 1 inch in thickness, and it is possible to weld from both sides, it will be well to bevel as shown in fig. 39. A diamond point or cape chisel may be used for beveling cast iron. Remember that careful lining up and clamping is very necessary when broken flanges or lugs are to be welded.

A larger blow-pipe tip is used. To overcome expansion and contraction—pre-heat. While welding is in progress and after its completion it is advisable to apply a blow torch or light a fire under some part of casting away from the weld.

Filling material—use cast iron filling rod containing a percentage of silicon. The percentage must not be too great or weld will be soft. **Flux**—cast iron flux is necessary.

Malleable cast iron is probably more difficult to weld and treat than any other metal. Castings to be made malleable are made of white iron. Use same process as cast iron with white iron filler.

Cast Aluminum.

Has a low melting point (1,200° Fahr., see page 539 for other melting points). A large welding flame is used. Aluminum is not generally used in pure form. Alloys of aluminum and copper or zinc are generally used. Alloys of aluminum and copper are

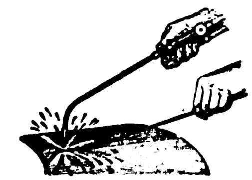

Fig. 21. Correct method of holding the blow-pipe with relation to the line of weld.

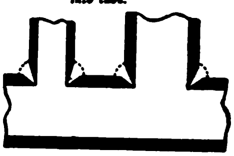

Fig. 35. Shows preparation of pipes before welding to form branches.

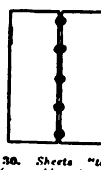

Fig. 30. Sheets "tacked" before welding to prevent spreading.

Fig. 36. Preparation of flange to be welded to thinner section plate.

Fig. 24 shows a section of one side of a steel cylinder and a convex head which is to be welded on. The weld should be made in the straight portion of the cylinder as shown, and not directly at the bend.

Fig. 25 shows the method of accomplishing the same result in the case of a concave end. If the parts are beveled as shown, the joint will be a strong one.

Fig. 26 shows correct method of welding pipe. The pipe, where possible, should be rolled away from the operator in such a way that the portion being welded will be on top. "Tacking" at several points is necessary before the actual welding is started. However, if rolling is impossible, the pipe may remain stationary and the operator can weld entirely around it without difficulty after some practice, although this method is bound to be somewhat slower.

Fig. 27 shows the proper method of preparing a shaft for welding. Note that this is beveled to a chisel edge and not pointed.

Fig. 28. If the shaft is pointed, the molten metal will fall upon the cold part of the shaft and adhesion will result, which means that the new metal is merely "plastered" on at certain points and is not "fused."

Fig. 29—When butt welding two lengths of plate, or when welding the longitudinal seam of a cylinder, it is advisable to "tack" along the line of weld before commencing on the finished weld. This will prevent the over-lapping of the sheets at the end farthest away from the point of welding. When starting to weld two lengths of sheet at one end, which have previously been placed in proper alignment, it will be found that they tend to spread apart as shown in illustration. As the welding progresses, this spreading movement of the sheets ceases and later they come together again with a tendency to overlap.

Fig. 30—"Tacking" holds the sheets in true alignment and prevents this overlapping.

Fig. 31—Another method of preventing over-lapping of the plates, in the case of cylinders, is to insert a wedge a short distance ahead of the weld, moving the wedge as the weld progresses.

In some cases when welding a longitudinal seam, it will be found advantageous to start to weld in the middle of the seam and work first toward one end and then toward the other.

Fig. 32—When welding angle iron rings to cylinders where the thicknesses are the same, both edges should be set up as shown.

Fig. 33—When the angle to be welded to the plate is thicker than the plate, apply the flame more on the angle than on the plate. This will tend to bring the parts to the fusion point at the same time. Metal must be added as shown by the dotted line.

Fig. 37. Patch plate bellied and with edges bevelled before welding.

Fig. 34—When welding a flat end into a tube, prepare the end as shown, making a driving fit.

Fig. 38. Bevelling cast iron. Note bevel does not penetrate entire thickness to be welded.

Fig. 35—To weld a branch into a pipe, prepare the work as shown, adding metal as indicated by the dotted lines.

Fig. 39. Bevelling from both sides in thick section of cast iron. Note: Points of bevels do not meet.

Fig. 36—The welding of flat flanges to tubes is an operation that requires care, as the flange is usually considerably thicker than the tube and has to stand a good deal of strain. The flange and tube are best prepared as shown. The welding flame should play more on the flange than on the tube.

Fig. 40. Fracture in the middle of a long bar to be welded. No precautions to overcome expansion and contraction strains are necessary, as the parts are free to move.

Fig. 37—When repairing cracks in plates, always see that the crack is bevelled through its entire thickness. The plate being welded should be free to move. It is impossible to provide for this, instead of attempting to repair the crack, use a patch. A patch piece should always be slightly bellied and have edges bevelled as indicated in illustration.

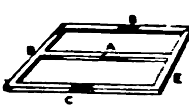

Fig. 41. Fracture in cross member (A) of frame. The broken bar will contract on cooling, causing a strain on the end members (D and E). Risk of fracture may be avoided by heating the side members (B and C), or by cutting at the corner (F). The cut (F) may be welded up without risk of fracture after the break (A) is welded and cooled.

Selection of blow-pipe tip—The size of tip to use for welding iron and steel depends upon the thickness of the metal. Do not forget that the flame should be neutral at all times.

CHART NO. 293-A—Oxy-Acetylene Welding—Continued.

*Fig. 27 should read: "Correct method of preparing shaft (bevelled to chisel edge) for welding."

easier to weld—less tendency to crack. **Parts** over ¼ inch thick must be beveled as in case of cast iron.

In order to prevent collapse during the welding and preheating operations, it is good practice to place a sheet of paper on the inside of the casting next to the crack to be welded. Back this paper with damp fire clay and pack up with asbestos fibre until a firm support is obtained. The paper prevents the fire clay from getting into the weld. With this light backing, or mould, the castings can be welded easily. The mould should be large enough to cover sufficient area around the crack so that the heated aluminum in the vicinity of the weld will not break down. Whenever a weld is to be made close to a bearing, it is necessary to remove the babbit (which would melt) and then clamp mandrels (fig. 16, chart 293) in the bearings to keep them in alignment.

Preheating should not be done except in cases where there is a projecting lug or flange. Preheating must be done carefully and slowly. A blow torch is generally used, but must not be left on one part too long. When pre-heating, test with a stick of half and half solder—if it melts on touching casting it shows sufficient heating.

Filling—Alloy rods or pure aluminum rods can be employed—same thickness as metal to be welded.

Flux—opinions differ. Use aluminum flux if any.

Copper, Bronze and Lead.

Copper radiates heat very rapidly and is also a good conductor of heat. Pre-heating and continued heating is therefore necessary. Prepared similar to steel and iron. Cover as much as possible with asbestos. Should be left free to allow for contraction when cooling. **Filling**; phosphor copper, **Flux** must be used, same as welding brass.

Brass—Pre-heating not necessary. Use special flux for brass and bronze. Filler; brass spelter. Tobin bronze with brass flux may be used where great strength is desired. Weld should be made rapidly, but white cone of flame must not touch metal.

Lead—can readily be welded but is known as "lead burning." (see page 471).

Welding Thin Castings.

The inexperienced operator will find it a big help to build a form of fire clay as a support for the broken sections while repairing thin castings. This holds the parts true and also assists in the control of the molten metal.

Whenever it is necessary to weld in a patch, a new piece of the same metal should be cut to the proper size and shape, the edges of both parts bevelled, and the patch held in place temporarily by "tacking," that is, welding at several spots some distance apart along the line to be welded. To hold a large patch in position while being "tacked," it may sometimes be necessary to drill a small hole in the center of the patch into which a length of rod can be inserted, and by which the patch may be handled. This hole may afterwards be plugged and welded up. Small patches, to be placed in difficult positions, may be conveniently handled by simply welding a filling rod to the center of the patch. This may later be melted off.

Sundry Uses.

Tool hardening—The welding flame will be found useful as a source of heat for the heat treatment of small tools.

Gear tooth hardening—Gear teeth may be hardened by playing the welding flame along the face of a tooth and then allowing the heat to be conducted away by the body of the gear. The intense heat of the flame permits of a single tooth being heated very rapidly, before much heat is conducted to the rest of the gear. As soon as the flame is removed the heat in the treated tooth is conducted away to the body of the gear. This causes hardening of the tooth. This operation is repeated until the desired depth of hardening is reached.

Teeth may be hardened by this method to a depth of about 3/32 inch. The rapidity with which the treated tooth may be chilled will be increased if the gear is partly immersed in water while the treatment is performed.

Burning battery terminals or connections —see page 471.

*Approximate Prices to Charge for Welding Broken Parts by the Oxy-Acetylene Process.

Cylinders, Water Jackets Fractures.

Double	$ 8.00 to $15.00
Single	4.00 to 8.00
Block of four or six	10.00 to 15.00
Lug or ears each......$3.50 two or more	3.00

Aluminum Crank Case and Lower Cases.

It is very difficult to determine an exact price on this line of work without a thorough examination of the fractures, but as a general rule the average cost of welding is as follows:

Top cases	$6.00 to $25.00
Lower cases	6.00 to 12.00

Manifolds Aluminum.

1 lug or ear....$1.50 Two or more $1.00 each.

Cast Iron.

1 lug or ear....$1.25 Two or more $0.75 each.

*Not standard, merely a suggestion.

Crank Shafts.

1 throw crank	$ 6.00 to $ 8.00
2 throw crank	8.00 to 10.00
4 throw crank	10.00 to 14.00
6 throw crank	12.00 to 16.00

Body Frames.

Two inches	$ 7.00
Three inches	8.00
Four inches	10.00
Five inches	12.00
Six inches	15.00
Eight inches	17.00

Rear Axle Housings.

Prices vary according to size and fractures, but they average from $3.00 to $18.00.

Lamp brackets	$0.50 to $1.50
Levers	.75 to 2.00

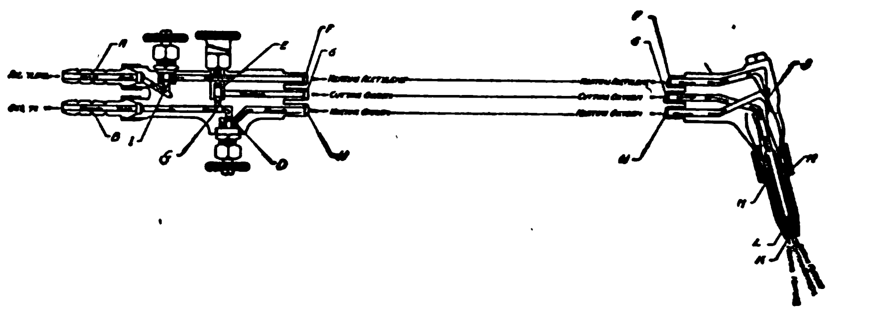

Fig. 45. Diagram illustrating the principle of the oxy-acetylene cutting blow-pipe torch.

Oxy-Acetylene Cutting.

The cutting blow-pipe is commonly used for cutting through various thicknesses of wrought iron and steel up to 14 inches. (Wrought iron and steel are the only metals that can be cut by this process.) As an adjunct to a welding equipment, it is used for bevelling and for cutting out patches and holes.

The process is based on the fact that a jet of oxygen directed upon a previously heated spot of iron or steel causes it to ignite, with the result that the metal, acting as its own fuel, burns away rapidly in the form of iron oxide. A special blow-pipe is provided for this work. (Fig. 45.)

The oxygen cutting blow-pipe cannot be used for welding any more than can the welding blow-pipe be used for cutting.

The same source of gas supply is used as for welding. The same acetylene regulator is used, but if work over 8 inches thick is to be cut, a special oxygen regulator must be employed. This is exactly the same in appearance as the oxygen regulator for welding, but it is fitted with a stronger spring and a higher reading outlet or "working" pressure gauge.

The special oxygen regulator as used for cutting thick work should not be used for welding, as the regulation is not delicate enough to maintain a strictly neutral flame, especially when the smaller tips are in use. The oxygen regulator for welding, however, can be used for cutting on work up to 1½ inch in thickness.

The oxygen cutting regulator is connected to the oxygen bottle in the same manner as the welding regulator. The cutting blow-pipe is connected to the gas supply through the regulators in exactly the same way as the welding blow-pipe.

There are two kinds of oxy-acetylene cutting blow-pipes, known as the central and following jet types. The central jet type has a number of oxy-acetylene heating flames surrounding a central hole through which oxygen only passes. The following jet type consists of one oxy-acetylene heating jet and one oxygen jet. The holes for these jets are usually drilled in the same tip, but sometimes have separate tips which are set close together.

Fig. 45 illustrates the principles of construction and operation of an oxy-acetylene cutting blow-pipe of the central jet type. The oxygen and acetylene supplies are connected up through the regulators and rubber hose to the hose nipples on the blow-pipe.

The outlet valves on both regulators and also all valves in the blow-pipe are closed. The gas is then turned on at the cylinders as in welding, and the regulators adjusted until the outlet or working pressure gauges show the working pressures specified on the instructions issued with the cutting blow-pipe by its manufacturer. The acetylene valve in the blow-pipe is then slightly opened and the blow-pipe lighted, the oxygen for the heating flame is then turned in at valve D of fig. 45. This permits oxygen to mix with the acetylene at J. The flow of the mixture of the gases is indicated by arrows. Valves D and I are adjusted until a neutral heating flame is produced. The cutting oxygen is then turned on at E.

The line of flow of the cutting oxygen is shown by arrows. The nipple or inner tip through which it discharges is interchangeable and manufacturers indicate in their instructions the number or size of tip to be used on different thicknesses of metal.

Watch the working pressure gauge on the oxygen regulator and see if it reads the right pressure for the metal to be cut as originally set, if not adjust regulator and when this is done readjust the heating flame if necessary. Do this as quickly as possible to avoid waste of oxygen. Now shut off the cutting oxygen at E and the blow-pipe is ready for work.

When the metal to be cut is sufficiently heated at the point where the cutting is to start, the cutting oxygen is turned on. When the cutting operation is once under way, the heating and cutting proceed together. The cutting operation is very simple and can be mastered in a few hours.

Cutting may be made to follow any desired line. When special forms and shapes have to be cut, it is advisable to make a special mechanical contrivance with which to steady and guide the blow-pipe and thus insure a clean cut. Hold the blow-pipe tip about ¼ inch away from the surface of the metal to be cut.

A cut should start from the edge of the metal whenever possible. When it is desired to cut a piece out of the center of a plate, start inside the circumference of the piece to be cut (fig. 46). On thick plates where the cut cannot be started from the edge, it may be necessary to drill a hole to get a quick start.

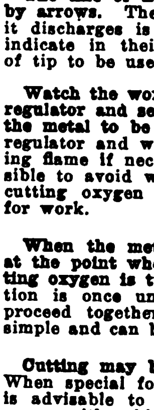

Fig. 46. Shows point of start (A) when cutting circular hole in plate.

Certain precautions are necessary before the operator starts to work on a piece of metal. A bucket of water should be near at hand for cooling the cutting tip when necessary. Both oxygen and acetylene should be shut off at the blow-pipe to extinguish the flame before dipping the tip of the blow-pipe into the water. To expel any steam formed inside the tip, turn on the oxygen valves at the blow-pipe and allow oxygen to flow for a moment before turning on the acetylene and lighting.

These and many other parts from an auto too numerous to mention can be welded successfully.

All up to date welding and cutting shops have the latest modern equipment installed to take care of all classes of work such as pre-heating cylinders, cases, etc.

The cutting process of this art consists of the cutting and wrecking of all kinds of "I beams," "channel iron," "girders," cutting of boilers," "tanks," "cutting and opening of safes," "steel pilings," etc.

Pure oxygen used in the process of removing carbon from cylinders is one of the latest and most advantageous features to the automobile owner.

The Cost of Welding.

Thickness of Metal	Size of tip to be used	Acetylene		Oxygen		Total cost of gas per hour	Approximate capacity per hour of welded seam
		Consumption per hour	Cost of gas per hour	Consumption per hour	Cost of gas per hour		
3/16" to 1/4"	No. 3	15 cu. feet	$0.30	17 cu. feet	$0.34	$0.64	15 to 20 lineal feet
5/16" to 1/2"	No. 5	43 cu. feet	.86	47 cu. feet	.94	1.80	7 to 12 lineal feet

Note:—In welding metals of from 3/16" to 1/4" in thickness, the average approximate capacity, expressed in terms of lineal feet of welded seam, would be from 15 to 20 feet per hour, being a cost for gas of from 3 to 4 cents per lineal foot. For metals 5/16" to 1/2" in thickness, the approximate capacity would be from 7 to 12 lineal feet per hour, being a cost for gas of from 15 to 25 cents per lineal foot.

Under continuous use with the No. 3 tip a cylinder containing 100 cubic feet of acetylene will run about 6 1/3 hours, while the same quantity of oxygen would run about 6 hours.

With the No. 5 tip, a cylinder containing 100 cubic feet of acetylene would run about 2 1/3 hours, while the same quantity of oxygen would run about 2 hours.

The Cost of Cutting.

Thickness of Metal	Acetylene		Oxygen		Time required per foot of cutting length	Total cost of gas per cutting foot
	Consumption per lineal foot	Cost per lineal foot	Consumption per lineal foot	Cost per lineal foot		
1/4"	.13 cu. feet	$0.003	.50 cu. feet	$0.01	1 minute	1 1/4 to 1 1/3 cents
3/8"	.18 cu. feet	0.0036	.90 cu. feet	0.018	1 1/4 minutes	2 1/4 to 2 1/3 cents

Note:—In continuous cutting through metal 1/4" thick, the cost for gas would be about $0.02 per running foot and the time about one minute.

For metal 3/8" thick, the cost of gas per running foot would be about $0.03 per foot and the time about 1 1/4 minutes.

When cutting 1/4" metal, a cylinder containing 100 cubic feet of acetylene would run about 12 hours, while the same quantity of oxygen would run about 3 1/3 hours.

For 3/8" metal, a tank containing 100 cubic feet of acetylene would run about 11 1/3 hours, while the same quantity of oxygen would run about 2 1/3 hours.

It will be noted that in the process of cutting the extra quantity of oxygen required is due to the cutting jet of pure oxygen which is used in addition to that mixed with the acetylene.

Tanks containing 200 cubic feet of gas would run twice as long as the 100-foot tanks.

The above estimates are based on acetylene and oxygen gas costing $2.00 per 100 cubic feet. Cost of labor should be added to the total cost of gas.

Where to Obtain Gas Tanks for Welding.

Oxygen and Acetylene Gas for use with Imperial Welding and Cutting Outfits.

Oxygen for welding and cutting can be obtained from the Linde Air Products Co. of Chicago, and New York, who have twelve plants and twenty-five warehouses in various parts of the country. They furnish oxygen in tanks containing 100 and 200 cubic feet respectively, with free use of tanks.

Acetylene Gas for Welding and Cutting:

There are several manufacturers of acetylene gas, as mentioned below: The Prest-O-Lite Company of Indianapolis, Ind., who have branches in nearly all the large cities of the United States.

The Searchlight Company of Chicago. This company has branches in many of the large cities of the United States.

The Commercial Acetylene Ry. Light & Signal Company of New York have numerous branches. We are advised they supply acetylene for welding and cutting. The tanks contain 120 and 225 cubic feet.

Approximate Shipping Weights are as Follows:

Linde	100 cu. ft.	122 lbs.
Linde	200 cu. ft.	150 lbs.
Prest-O-Lite	100 cu. ft.	85 lbs.
Prest-O-Lite	300 cu. ft.	220 lbs.
Searchlight	100 cu. ft.	75 lbs.
Searchlight	225 cu. ft.	180 lbs.
Commercial	120 cu. ft.	120 lbs.
Commercial	225 cu. ft.	180 lbs.

Weight of acetylene is approximately 14 1/3 cu. ft. to a pound.

The price of oxygen and acetylene varies somewhat, depending on location. Prices in the extreme West and South being somewhat more than in the East. The prices in the East for both oxygen and acetylene are approximately $2.00 per hundred cubic feet at the filling station or warehouse.

You can obtain full information regarding oxygen and acetylene by corresponding with the above companies at the branch nearest to you.

To provide a constant supply of gas for your shop, you can no doubt arrange to get the use of from three to six cylinders or more, according to requirements which would eliminate possibility of running out of gas by having extra cylinders on hand for use while getting empties recharged.

Your automobile supply house with whom you are trading may be able to give you additional information on this subject.

Oxy-Hydrogen.

An important feature to the Imperial welding and cutting equipment is its adaptability for use with oxy-hydrogen as well as oxy-acetylene. When it is desired to equip for both oxy-hydrogen and oxy-acetylene, the only change necessary is the addition of one hydrogen regulator and a set of hydrogen tips.

Tips for welding as well as cutting with hydrogen can be furnished. The tip is marked with the pressure of gases required.

Where a supply of hydrogen is available at reasonable prices, it is recommended in connection with oxygen for cutting of wrought iron and steel of any thickness. The cut will be found smoother and the operation more economical than by the use of acetylene for the preheating flame.

For welding in general repair work, such as gears and castings, aluminum crank cases and other alloyed metals, the use of the oxy-hydrogen flame is recommended. For welding thin sheet steel, from 16 gauge up, the oxy-hydrogen flame is found very effective. Its temperature being about 4,000 degrees F., the metal is not burned so easily and as hydrogen contains no carbon, the weld is softer and very uniform. Cast iron may be welded with oxy-hydrogen very successfully up to 3/8" in thickness.

For welding steel of more than 1/4 inch in thickness, the oxy-acetylene flame should be used under all circumstances.

Miscellaneous.

Fig. 5—Pre-heating furnace for cylinders. This subject is explained on page 721. When welding is finished the cylinder should be covered with fresh layer of charcoal, heated—then allow to grow

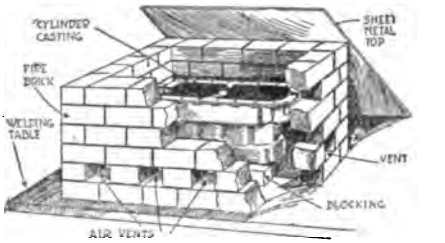

Fig. 5—Brick oven for preheating work. The work should remain in the oven while the welding is done

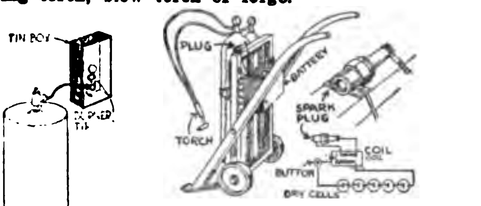
cold slowly. Many shops will not take in water jacketed cylinder work—due to difficulty in the job holding. Cause generally due to improper pre-heating. **Small jobs may be pre-heated with welding torch, blow torch or forge.**



A means of electrically lighting the welding torch is shown above. A box, holding several dry cells, and a spark coil, is mounted at the rear of the welding truck, and is connected to a spark plug attached to the top of the frame. The plug is thrown into operation by a push button connected into the battery circuit. This system of lighting is adapted to short welding jobs.

Fig. 4—A welding pilot light: When the gas in the welding tank becomes too low for welding purposes there is still sufficient gas for supplying a pilot light as per fig. 4. The light comprises a small gas tip arranged in a tin box as shown.

Pointers on Welding.

1–Always shut off the gas at the cylinder valves when the work is finished.

2–Never leave pressure in the regulators when not in use. The pressure gauges will indicate.

3–Never clean out a blow-pipe tip with a sharp, hard tool.

4–Before attaching rubber hose to blow-pipe or regulator, make sure that the inside of the hose is free from dust or powder (used as a preservative), which is apt to choke the blow-pipe.

5–Do not under any circumstances use oil or grease on oxygen cylinder valves or regulators.

6–Always see that the hose is clamped securely to the blow-pipe and regulators before using.

7–Always turn on the cylinder valves slowly.

8–Never open acetylene cylinder valve more than one full turn of the spindle.

9–In case the flame goes out at the tip or burns back of the tip, shut off first oxygen, then acetylene at the blow-pipe.

10–Always have a bucket of water handy while welding or cutting for cooling the blow-pipe tips when necessary.

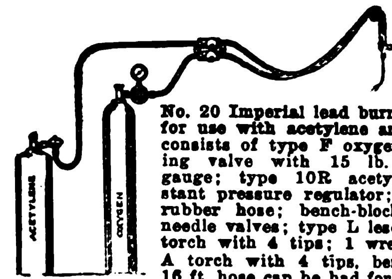
11–If flame is not blue and part being welded is smoked black then the oxygen line is likely to be stopped up or tank is empty.

12–In disconnecting an empty acetylene cylinder from the welding outfit, remember to CLOSE THE CYLINDER VALVE tightly. Remember that the acetone in an empty cylinder is inflammable, and that, should the temperature in the room increase, an open valve would permit vapor to escape, as well as any slight quantity of gas which might yet remain in the cylinder. For these same reasons, the railroads require that valves be closed before shipping.

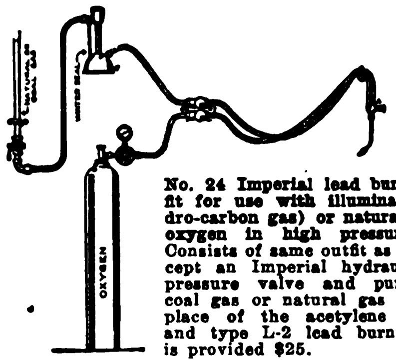
13–Remove "inflammable" red labels from acetylene cylinders **before shipping** back and ship as "empty returned gas cylinder" to get lowest freight rate.

Lead Burning With Gas.

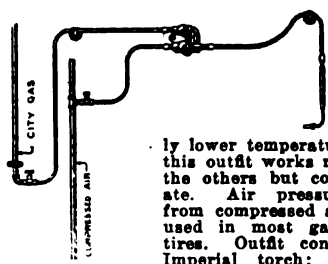
Lead burning is used for storage battery work, as explained on pages 471, 472. Gases or a combination of gases which can be used are given below. In addition to using the flame for lead burning it can be used for welding light metals. No's. 20 and 24 are used most.



No. 20 Imperial lead burning outfit for use with acetylene and oxygen consists of type F oxygen regulating valve with 15 lb. pressure gauge; type 10R acetylene constant pressure regulator; 35' $\frac{3}{16}$" rubber hose; bench-block with 2 needle valves; type L lead burning torch with 4 tips; 1 wrench. $25. A torch with 4 tips, bench-block, 16 ft. hose can be had for $9 where one is already equipped with a welding outfit using oxygen and acetylene.



No. 24 Imperial lead burning outfit for use with illuminating (hydro-carbon gas) or natural gas and oxygen in high pressure tanks. Consists of same outfit as above except an Imperial hydraulic back-pressure valve and purifier for coal gas or natural gas takes the place of the acetylene regulator and type L-2 lead burning torch is provided $25.



No. 27 Imperial lead burning outfit for use with illuminating (city) gas and compressed air. On account of the relatively lower temperature of this flame, this outfit works much slower than the others but costs less to operate. Air pressure is obtained from compressed air tank which is used in most garages for filling tires. Outfit consists of type O Imperial torch; type O bench-block; 17' hose; gas shut-off cock; air shut-off cock $12.

Torch For Radiator Work.

Although the soldering iron, which is drawn to a very fine point, is used extensively for soldering radiators in close places, the torch can also be used, especially for reaching the inner part of cells of a cellular radiator.

The torch must throw a very fine needle point flame.

The type R-1 torch, not illustrated, of the Imperial make is suitable for this work and operates from city or coal gas and is similar otherwise to No. 27, price $4.

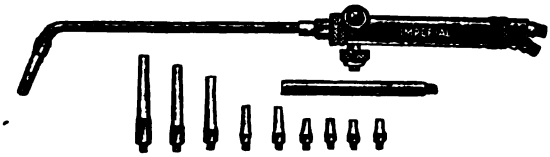
Gasoline Gas Generator.

A gasoline gas generator manufactured by F. L. Curfman, Maryville, Mo., is a very satisfactory method of generating gas for a torch for radiator repair work where gas is not obtainable and the price is very reasonable, $12.50.

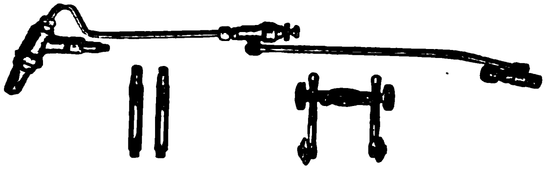
A gas torch No. 70, to operate from this gasoline gas generator throws a needle point flame and sells for $3.00. Supplied by F. L. Curfman.

HART NO. 293-C—Pre-heating Furnace. Pointers on Welding, Lead Burning.

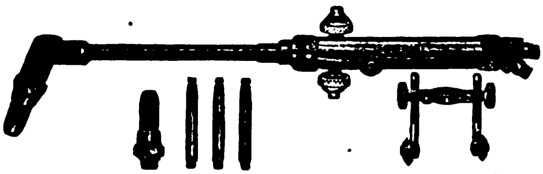
combination soldering iron, welding and lead burning torch is manufactured by B. E. Hicken, Sod-Tor-Lite Co., ·airie Hill, Mo.



Type B welding torch as furnished with Imperial outfits Nos. 1, 4 and 5 .... $25.00

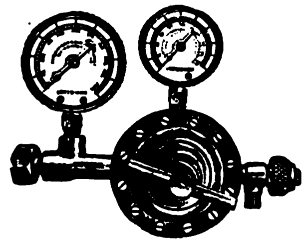


Type DB cutting attachment for use with type B welding torch. Makes it possible to weld or cut with one torch, as furnished with Imperial outfit No. 4 .... $20.00



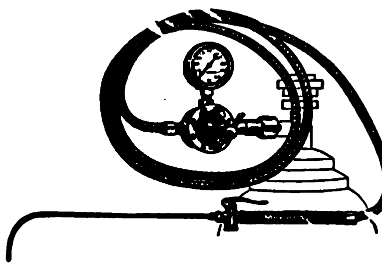
Type E cutting torch as furnished with Imperial outfits Nos. 3 and 5 .... $45.00

No. 1 welding outfit in carrying case.

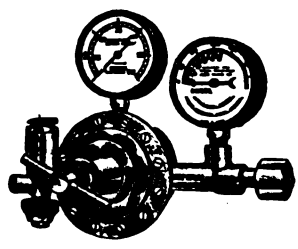


Type AA Acetylene regulator as furnished with all Imperial welding and cutting outfits $22.50

Imperial portable truck.



No. 6 Imperial Oxygen decarbonizing outfit for removing carbon from inside of cylinders and head of piston. See page 624 explaining the operation.



Type A Oxygen regulator as furnished with all Imperial welding and cutting outfits $25.00

Welding, Cutting and Decarbonizing Outfits.

No. 1 Imperial welding outfit: For all general welding work, from thin sheet metal to heaviest castings. Consists of type B welding torch with ten welding tips, extension, decarbonizing torch, regulators, gauges, hose, connections, goggles, complete supply of welding materials, ready for service. Weight, approximately 75 lbs., net, each . $75.00

No. 3 Imperial cutting outfit. Intended for light and heavy cutting, from sheet metal to heaviest iron and similar work. Consists of type E cutting torch with 2 housings and 4 tips, regulators, 4 gauges, hose, connections, goggles, hand-book, carrying case, etc., complete ready for service, net, each $95.00

No. 4 Imperial combination welding and cutting outfit: A splendid equipment for all general work, garages, repair shops, etc. Combination welding and cutting torch performs both operations with one torch. Consists of type B welding torch with type DB cutting attachment, ten welding and three cutting tips, decarbonizing torch, regulators, gauges, hose, connections, goggles, complete supply of welding materials, ready for service. Weight, approximately 80 lbs., net, each $90.00

No. 5 Imperial duplex welding and cutting outfit: This is a combination of the Nos. 1 and 3 outfits for both welding and cutting and is the best all-purpose apparatus obtainable at any price. Being fully adequate to handle all kinds of welding and cutting within the limits of the process. Consists of a complete No. 1 welding outfit as described, and also includes a type E cutting torch with two housings and four tips and an extra pair of goggles and 25-foot lengths of hose. Weight, approximately 90 lbs., net, each $120.00

No. 6 Imperial oxygen decarbonizing outfit: For decarbonizing gas engine cylinders. Consists of type G decarbonizing torch, type D regulator, gauge, hose, connections, etc., net, each $15.00

The Imperial Brass Mfg. Co., 1200 W. Harrison St., Chicago.

CHART NO. 293-D—Oxy-Acetylene Welding, Cutting and Decarbonizing Outfits.

A book on Welding and Cutting as supplied with the Imperial Outfits can be secured of A. L. Dyke, Granite Bldg., St. Louis, Mo., price $1.10 prepaid.

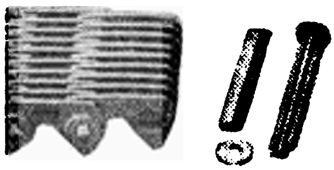


Fig. 1

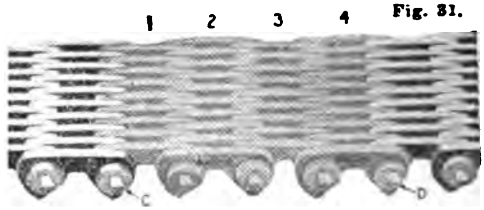
Fig. 31.



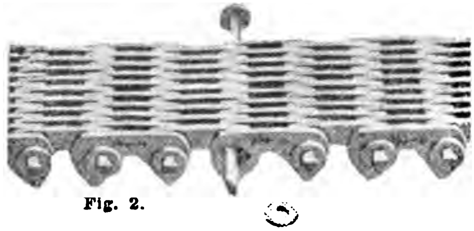


Fig. 2.

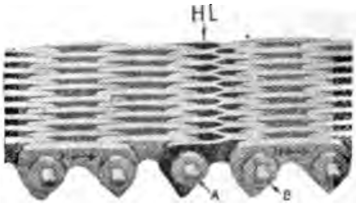

Fig. 21

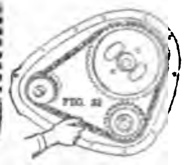

Silent Chains.

Are used to drive cam shaft, generator, water pump, magneto, fan etc., instead of gears.

The Morse silent chain as used on many cars (enumerated below), is different from other silent chains only in that the Morse employs two pins in the joint, one called the "seat pin" and the other the "rocker pin."

To properly connect the ends of a Morse silent chain: Place chain over wheels to run in direction indicated by arrows. On all automobile front end drives, the arrow side of chain will be the near side, as shown in figs. 1 and 2.

Bring ends of chain together and lap the link plates in regular order as shown in fig. 2; insert "seat pin" (with washer riveted on one end) from far side of chain, taking care that the ribbed side of pin points in direction of rotation of chain as shown in fig. 2.

Insert "rocker pin" from near side of chain as shown by fig. 2, with segmental, or pointed, side of pin against flat side of "seat pin," also toward direction of rotation of chain. The relative positions of the two pins, when properly inserted, will be as shown by fig. 3, chart 294-A.

Place washer on end of "seat pin" and, after backing up with bar or wedge, rivet over the end with a few sharp blows of the hammer.

To shorten chain one pitch by removing the "hunting link." All chains containing an odd number of links must include the thin leafed section marked "HL" in fig. 21. This row of leaves (collectively) is called the "hunting link."

To remove same, move chain until the hunting link is on top of a wheel; then with chisel in vertical position and edge of blade at right angles to plane of washer, strike sharply with a hammer until washers A and B are split sufficiently to make them fall off. This releases pins in the two joints which can then be driven out and the leaf-plates of hunting link will fall away when chain is lifted up.

The chain is thus reduced in length one pitch (one link), and all that is necessary to put it again in running order is to bring the ends together, mesh the link plates in regular order and make proper connections as stated above. The pitch of a silent chain is the distance from center to center of the pins.

To shorten chain one pitch, by removing four links and inserting three, one of which is the "hunting link." Arrange chain with arrow side as the near side, either flat (as shown above) on some solid foundation or on top of one of the wheels.

Select a joint at the HEAD of an arrow, and, with hammer and chisel, cut washer C (fig. 31) until it falls off. Move to the right four links and cut washer D, also at HEAD of an arrow, in same manner.

Be careful that each severed washer is at HEAD of an arrow, as otherwise leaf-plates of three-link section will not mesh in regular order with chain.

Drive pins from joints C and D and remove links marked 1, 2, 3 and 4 in fig. 31. Insert a three-link section in place of removed section, making sure that arrow on new section points in same direction as arrows on old chain. Bring ends together, mesh leaf-plates in regular order and make connections.

NOTE—It is only necessary to remove four links and insert the section of three links, as described above where chains are used with an even number of links and do not contain a hunting link HL, fig. 21. If the chain contains a hunting link, it should always be shortened as described in instruction fig. 21.

Some of the engines on which Morse "front-end" drive is used: Cadillac; Chalmers; Clyde; Colonial; Drexel; Erie; Ferro; Gray; Hackett; Haynes; Hupmobile; Jeffery; Jewett; King; Lozier; Scripps-Booth; Monitor; Maxwell; National; Nash; Olympian; Pullman; Packard; Winton; Princess; Stearns-Knight.

Fig. 36.

*Chain Adjustment.

Various methods are used for adjusting chain tension: For instance, if chain drives generator shaft, the generator can be moved in slot holes to adjust chain tension, or shaft on which sprocket is mounted can be rotated on an eccentric bearing, or if mounted in separate case, shims can be installed under the case.

To adjust while running, tighten chain until noisy, then slacken to the point where noise ceases. Chain should be tight as possible without causing noise.

To adjust where cover is removed, as in fig. 32, take hold of chain and pull long strand as far as it will go to test the free movement. The total free movement will vary with the length between sprockets. If length is from 5 in. to 7 inches, the total free movement should be ⅜" to ½". If 8" to 11", ½ in. to ⅝ in. If it becomes noisy remove 2, 4 or 6 links each; never an odd number.

Morse adjustable sprocket, fig. 36 is designed for shafts, as generator shafts, etc., when shaft cannot be moved for adjustment. The sprocket (fig. 36) is mounted on a bearing which is eccentric to the shaft. By rotating the bearing, sprocket is moved, thus adjusting chain tension. The drive is through sprocket to a plate type universal joint at left end (fig. 36), to shaft. This joint also tends to relieve vibration of chain and is called a "vibration dampener." (Morse Chain Co., Ithaca, New York.)

CHART NO. 294—How to Connect, Shorten and Adjust the Silent Chain. (Morse as an example.) An Adjustable Silent Chain Sprocket and Vibration Dampener.

See pages 89 and 835 for remeshing timing gears using silent chains, also pages 411, 112 and 113. *Chain wears in the pins, so much so it will often have sufficient slack to strike case covering it. A 17" chain has been known to have 1 1/16" slack after 8000 miles running. In this case a new chain is necessary, or enough links removed to take up the slack.

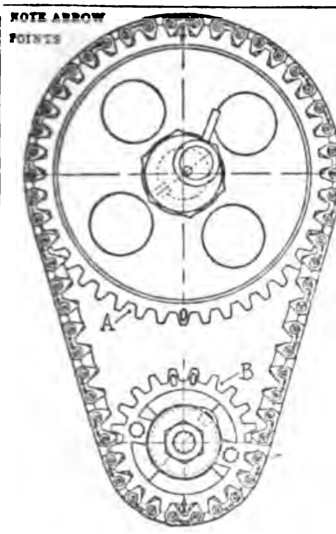

Fig. 4—The marks on the camshaft gear (A) should line up with those on the crankshaft gear (B), before the gears are removed, and should be replaced in exactly the same position

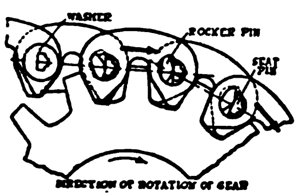

Fig. 3—In replacing the chains, make certain that the arrows point in the direction of rotation, and that the rocker and seat pins are in the position shown. Otherwise the chain will quickly ruin itself

Detecting Looseness.

Looseness in the silent chains grows so gradually that it is scarcely to be noticed until the chains have become so loose that they jump the teeth of the gears. This, of course, destroys the timing. The amount of looseness may be felt by grasping the generator shaft and rocking it back and forth. Any great amount of looseness destroys the proper timing of the valves and necessitates a replacement of the chains.

Disassembling.

After removing all parts so that access is gained to chains, then turn the engine until one tooth of the camshaft-driven sprocket, "A," fig. 4, which is marked with an arrow, is diametrically opposite the tooth with an "O." A tooth on the crankshaft sprocket "B" has a similar arrow upon it, and the two teeth opposite each have an "O" mark. All should line up, as shown in fig. 4.

Apply the special gear puller, as shown in fig. 2, to the crankshaft gear, next apply the special camshaft gear puller, as also shown in fig. 2.

Working both pullers together, remove both camshaft and crankshaft gear, at the same time sliding the distributer housing and fan drive chain forward. All will come off together. (The usual method is first to cut the riveted head of one of the seat pins on the driving chain, and remove the seat pin and rocker pin. The driving chain is then removed. In refitting the new chains by this method, it is necessary to rivet the seat pins while on the gears and in the case. This is a difficult and tedious job. By the method outlined in this article, the chains are riveted on the bench easily, quickly and with a certainty of its being right.) Place the gears, chains, etc., on the bench, removing the camshaft driving chain.

The Repair.

Cut off the riveted head of one of the seat pins on the fanshaft driving chain, and remove the seat pin and rocker pins. Remove the fanshaft driving chain. Clean all parts with gasoline and examine gears for wear. If worn, the faces of the teeth will be ridged, showing the marks of the chain links, and must be replaced.

Place new fanshaft chain over the fanshaft gear with arrows on outside links pointing in direction in which the chain is to run (fig. 3.)

Rivet a small washer onto one end of a seat pin in a vise. Bring the ends of the chain together. Insert a rocker pin, then drive the seat pin with its washer into place. Be certain the rocker pin and seat pin are in the position shown in fig. 3. Head over the end of the seat pin. Rivet up the new camshaft driving chain in the same manner.

Assembling.

Place the camshaft gear on the fan chain, with the mark "O" in the lowest position. Place the camshaft chain on the gear, with the arrows pointing in the direction of rotation. Place the crankshaft gear into the camshaft chain with the marks as shown in fig. 4. Now slide the whole assembly into place on the engine, driving the gears home with a brass bushing and machinist's hammer. Replace nut and washer on crank shaft end and then replace parts which are disassembled.

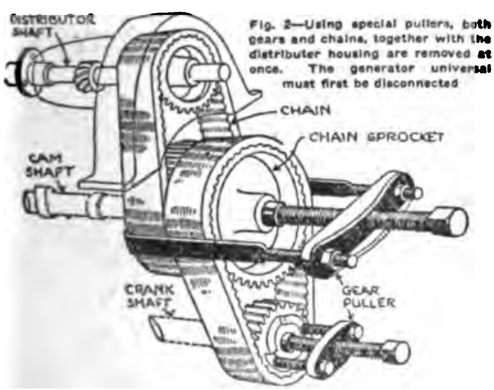

Fig. 2—Using special pullers, both gears and chains, together with the distributer housing are removed at once. The generator universal must first be disconnected

The Valve Timing.

The valve timing was automatically cared for in replacing the camshaft driving chain as directed, providing the valve tappets have the proper clearance. The exhaust tappet should have .008 inch clearance, the intake .002 inch; the exhaust should close and the inlet open on dead center. The inlet should never open at a point more than 1 in. on the flywheel, past dead center.

Ignition Timing.

Open compression relief cocks, crank engine until No. 1 cylinder (the one nearest the radiator, on the right hand side when facing the engine from the front) is on the firing center. The pointer above the flywheel will then be exactly over the mark 1-5 on the flywheel, and both valves of No 1 cylinder will be closed.

With the timer open, as shown in fig. 11, page 132, loosen lock screw (A) slightly. Then set spark lever as shown in fig. 5.

Connect test lamp into primary circuit, as shown in fig. 7. When the breakers are closed the light will be lighted, if the ignition switch be closed.

Replace distributor rotor and turn by hand until the distributor brush is under the terminal marked No. 1 on the distributing cover. Turn on the ignition switch. The light should light. Turn rotor very slowly, in the direction it is driven by the engine, until the lamp goes out. Remove rotor, tighten screw (A) of fig. 11 (page 132).

Replace rotor and retard spark. Then move the spark lever slowly back toward the point of the arrow, as shown in fig. 5. When the point of the arrow is reached the light should go out. If not, reset rotor and cam as directed.

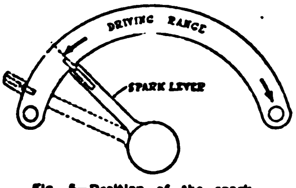

Fig. 5—Position of the spark lever, when timing the ignition. The end of the lever on the quadrant should line up with the point of the arrow as illustrated

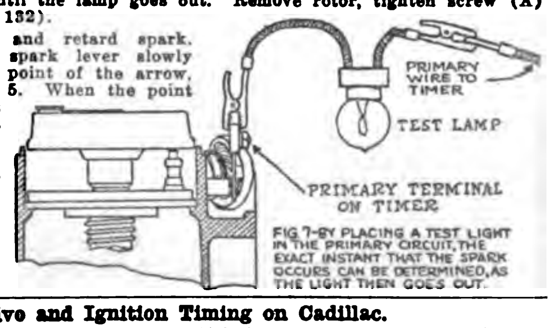

FIG 7—BY PLACING A TEST LIGHT IN THE PRIMARY CIRCUIT, THE EXACT INSTANT THAT THE SPARK OCCURS CAN BE DETERMINED, AS THE LIGHT THEN GOES OUT.

CHART NO. 294-A—Replacing Silent Chain. Valve and Ignition Timing on Cadillac.

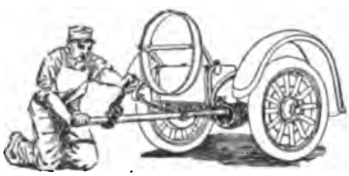
Chain alignment—when tightening a silent chain by movement of generator—if it is not moved in perfect alignment it will cause chain and sprocket to wear rapidly. This is most important. See also pages 128 to 133.

INSTRUCTION No. 46-D.

USEFUL SHOP HINTS AND DEVICES: Labor Saving Short Cuts in Repairing. Time Savers for the Shop. Miscellaneous Shop Kinks. Tools for Straightening Fenders, Etc.

Miscellaneous Shop Devices.

This section is intended for miscellaneous shop hints, useful and time saving devices and methods for the shop. The material is collected from various sources. The writer has not tried out any of the examples shown but having taken same from reliable journals, the matter is evidently practical and many different repair jobs can no doubt be made easier or quicker by the use of them.



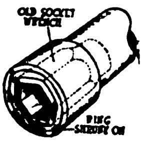


*Fig. 1—Extension socket wrench: By mounting a socket wrench head in the end of a 4 ft. length of 2-inch pipe, an extension wrench is made that facilitates the removal or replacement of the nut on the rear axle drive pinion. A steel ring is first shrunk on the end of the pipe, to provide strength, the pipe is heated red, and the cold socket wrench head driven into the pipe. When cool, the head is firmly held in place. Because of the long handle, a pipe wrench may be used to get a leverage, and the workman may work from an uncramped position.

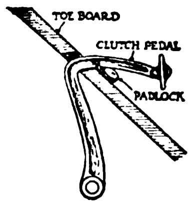

Fig. 2—One method of locking a car. Hole is drilled in clutch pedal arm for the insertion of a padlock. Prevents use of clutch.

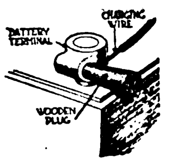

Fig. 2A—To attach charging wires to batteries where charging is done continuously, a wooden plug is handy.

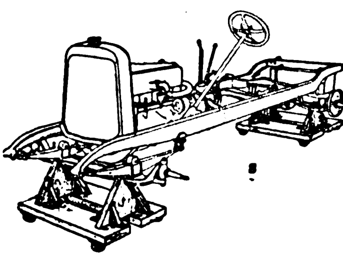

Fig. 3—Axle stand: Work is facilitated by the use of this special stand. The one illustrated is fitted with rollers and permits the chassis to be moved about, rendering the parts more accessible.

*From Motor World.

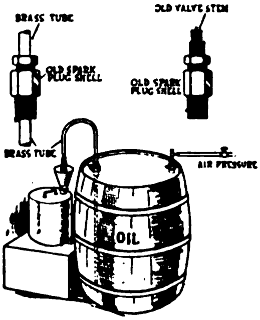

*Fig. 5—It is difficult to transfer oil from the common oil barrel to a smaller container unless some special outfit is at hand, such as illustrated. The oil is forced by air pressure from the barrel. Air pressure is applied through a valve that is an ordinary tire valve soldered into an old spark plug shell, which in turn is screwed into a hole in the barrel. The oil is delivered through a bent brass pipe, passing through a second spark plug bushing, also screwed into a hole in the barrel. This pipe must be long enough to extend nearly to the bottom of barrel, as shown by dotted lines. Packing is placed between the bushing of the plug and the shell, so that the tube may be adjusted to any barrel, and the amount of oil is readily regulated by the pressure applied.

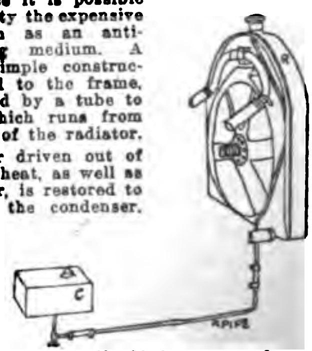
Fig. 6—A self-opening repairshop door is shown. The door is of the sliding type, hung on a horizontal track, but counterbalanced with weights swung over a pulley so that it automatically opens when the catch is released. This catch is of the hook type, and connected with a hinged board placed across the roadway, the car itself releasing the catch and allowing the door to open. One of these hinged boards is placed both on the inside and the outside of the door, so that one entering or leaving has only to get out of the car once.

Fig. 7—Cadillac patented condensing device: With this device it is possible to use with safety the expensive alcohol solution as an anti-freezing cooling medium. A condenser of simple construction is attached to the frame, and is connected by a tube to the overflow which runs from the upper tank of the radiator.

Alcohol vapor driven out of the solution by heat, as well as any water vapor, is restored to liquid form in the condenser.

When the radiator gets cold, the vacuum produced by the contraction of its contents automatically causes surplus liquid in the condenser to return under atmospheric pressure to the radiator. (This device is patented and merely shown to explain the principle.)



Straightening Bent Frames, Etc.

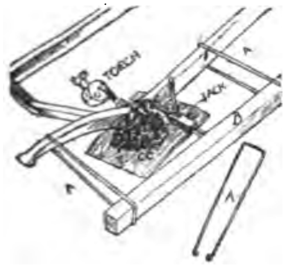


Fig. 1.

Fig. 1—Straightening a bent frame: To make the repair, the radiator is removed, a pan of charcoal placed under the frame, and pieces of charcoal heaped around the bend as shown; the frame is then heated up about the bent portion by playing upon the pile of charcoal with the flame of a blow torch.

As the frame is brought to a cherry-red heat the device A is applied and used in connection with a wooden beam B which supports the jack.

The torch now is set aside, the charcoal removed, and while one man carefully operates the jack and slowly draws the bent member back to its proper shape, another assists the operation by tapping and shaping the heated section with a hammer.

This hammering is quite necessary and an important factor in bringing about a successful result as it assists the molecular action of the steel, and prevents the end of the frame from springing back out of line as the job cools off.

The entire straightening process must be done while the injured section is red hot and the job completed before the red color is lost.

Fig. 2.

Fig. 2—Bent frame horns may be pulled back into place by a chain, providing the force is applied in the proper place. The method of attaching the chain is shown, and the force is applied by twisting the chain with a steel pinch bar. A jack, placed against wooden blocks and with a chain sling over it as shown, may be used to straighten the side members of the frame.

Fig. 3—Frames may be straightened without heating and sometimes without even dismantling the car by means of the simple device shown. It consists of a wooden beam 4 in. x 6 in. x 5 ft., reinforced with iron ¼ in. thick on each side. The beam forms the base of the device, to which are attached the steel arms which fasten to the frame. A powerful jack is used to apply the required pressure to bring the frame back to normal. A chain may be substituted for either of the arms.

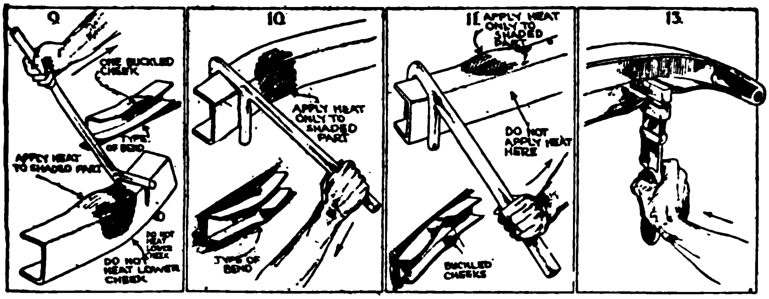

Fig. 9—When one cheek and part of the face is buckled, only the bent parts should be heated. Fig. 10—When the face is buckled very little heat should be applied to the cheeks. Fig. 11—When both cheeks are buckled heat should not be applied to the face but to the shaded portion. Fig. 13—Small crimps may be taken out with heat and a monkey wrench

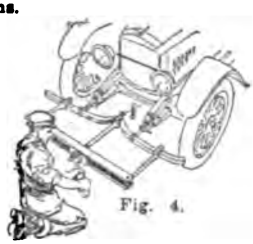

Fig. 4.

Fig. 4 — Straightening dents in bumpers and similar articles can be done in minimum time with the device illustrated. It is not necessary to remove the bumper from the car. The central member, which does the pulling, may be slid from one end to the other, as required, so that a dent in any part of the bumper may be removed.

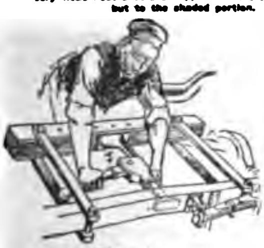

Fig. 3.

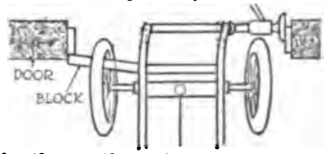
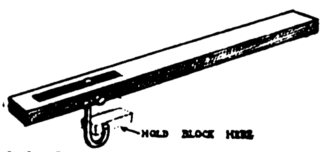
Easy method of removing dents from fenders with the use of a shaped wood block



Another method of straightening a bent frame.



A fender straightener made of oak 8x4, 4 ft. long.

Fig. 14.

Fig. 14—A **wooden crank shaft support** for fitting connecting rod bearings to crank shaft when removed from engine.

Fig. 15—A **Soldering iron** stand which can easily be made and well worth the time.

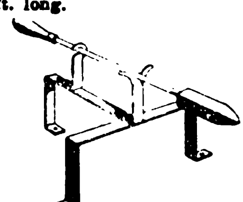


CHART NO. 295—Straightening Bent Frames. Straightening Bumpers, Fenders, Etc. (see also page 745.) **A Car Lifting Device.**
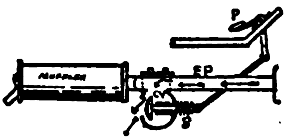
(Motor World.)

Fig. 3—Fitting a muffler "cut-out." Mufflers sometimes are not large enough or are clogged up and offer "back pressure" or resistance to the full passage of the exhaust. A "cut-out" is helpful in climbing hills and to help keep engine cool. The muffler cut-out is also a convenient method of ascertaining (by listening), whether all clyinders are firing regularly.



Muffler "cut-outs" are installed by cutting a hole in the exhaust pipe just ahead of the muffler. Fittings can be had from supply houses ready to fit and with full instructions. (see also page 84 and page 608.)

Attention to the cleaning of the muffler must not be lost sight of, for this is a point having a great effect upon efficiency. For open cars the writer considers a cut-out a necessity; not for roaring through towns or villages, but for the purpose of testing the firing and carburetion.

Although it is necessary to remove the muffler for a thorough cleaning, it is quite possible to effect a satisfactory temporary cleaning of the badly obstructed passages by tapping its sides all over lightly with a hammer or mallet. The result will be that much sooty accumulation will be knocked off and blown out through the tail pipe.

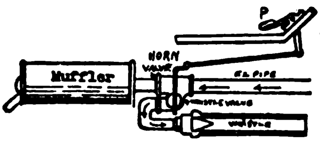


Fig. 4—Fitting an exhaust whistle: The exhaust whistle is blown by the exhaust pressure, for instance; instead of the exhaust going out into the open air, as in muffler cut-out, fig. 3, it passes into the whistle.

When fitted to an exhaust pipe the exhaust is temporarily cut off from the muffler and thrown into the whistle by a special valve attached to the exhaust pipe. Multiple engines blow a whistle almost steady, but single and double cylinder engines blow in jerks or uneven blasts.

Fig. 3—Testing shaft alignment: When the engine is overhauled the setting of the crankshaft with respect to the gearbox shaft should be carefully tested. The simplest way to do this is to arrange an indicator on the gearbox shaft, as shown in the illustration. This consists of a stiff, straight piece of wire clipped to the shaft, and then bent at right angles in the form of a pointer. If the centers of the shafts exactly coincide this pointed end will clear the edge of the flywheel an equal amount all round. If the centers are slightly out of alignment the pointer will be nearer the flywheel edge at one part of its circumference than at another. By having a sliding adjustment to the pointer a very accurate setting can be made. The gearbox can always be slightly packed or raised by means of very thin sheet metal shims, placed under its supports, to effect any adjustment required.

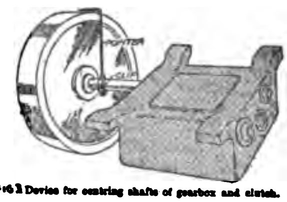

Fig. 3 Device for centring shafts of gearbox and clutch.

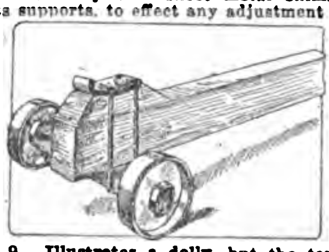

***Fig. 9.** Illustrates a dolly, but the top hooked member should have another hook opposite so that axle will set into the space. Chains with catch hooks should be provided to pass over axle to prevent side play.

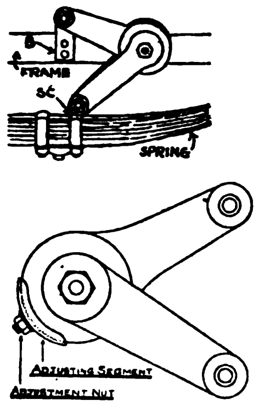

Fig. 7—Attaching Connecticut shock absorbers: Shock absorbers are necessary accessories. They prevent the rebound of springs after the spring action and thereby prevent springs being broken by the sudden up motion of car which is common in going over crossings, etc.

If properly fitted, they are worth many times their cost. **To fit—first** fill the grooves inside the bushing in the end of each arm with graphite grease.

In order to secure satisfactory results it is important that the angle of the arms be correctly adjusted so that the cam which operates against the springs in the absorber will be in normal position when the car is loaded and standing still.

Care should be taken that the absorbers are so located that they will not strike the frame when the car is in motion. After the fittings have been attached, slip the absorbers on to the studs of the fittings by loosening up the adjustment nut, so that the arms can be pulled apart any desired distance.

Load the car with full number of passengers the car is designed to carry and tighten up the adjustment nut. The lock washer should be on the stud and the nut tightened securely so that there will be no danger of the adjusting segment slipping. See that the cotter pins are all in place in the end nuts.

After the absorbers are attached no further adjustment or attention is required. (**Manufacturers** are Connecticut Shock Absorber Co., **Meriden,** Conn.) See page 26 for other types.

Towing In Disabled Cars.

Fig. 30—A tow-bar whereby two cars may be brought in by one driver. A towing bar, attached to the rear of the driven car, pulls the towed car by a clamp in the front axle. The bar extends behind the axle, and a stud on a clamp on the tie rod goes in a hole in the bar. In this way, when the bar turns, it moves the tie rod, and the towed car follows its leader.

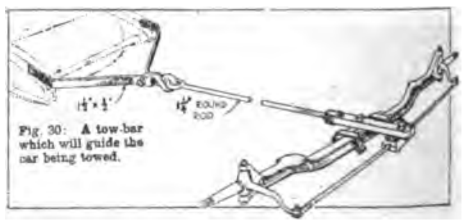

Fig. 30: A tow-bar which will guide the car being towed.

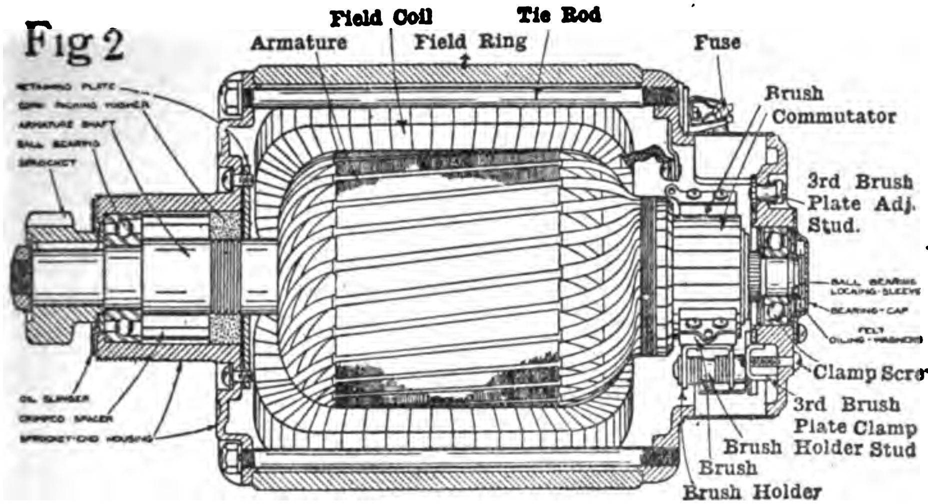
Fig. 9: A dolly for towing in cars where either the front or rear axle is disabled. For instance, if rear axle is out of commission and car cannot be towed from the front end, then it is necessary to place a dolly under rear axle and tow car backwards, or from the rear end. In this instance the steering wheel can be tied by passing a light rope around windshield brace, then tied to steering wheel then to other side of windshield brace which will keep the front wheels in line.

The dolly can be made of heavy metal wheels 11" di., 6" hub and 1½" spindle. A tongue, preferably an I-beam steel member about 8 or 10' long with a coupling pin to couple onto the tow link of the service car (see fig. 1, page 759), is mounted on the heavy metal axle of the dolly. A hooked shaped flat piece with a hook at each end is provided to set the axle or differential housing on and to hold axle in place. Then chains are passed around the axle housing and fastened to axle of dolly, in order to keep the axle from moving sidewise. The rear end of service car is then coupled to end of dolly and car towed backwards. The axle of dolly, in fact all parts must be very substantial as the vibration is very great.

CHART NO. 295-A—Muffler "Cut-Out." Exhaust Whistle. Testing Shaft Alignment. Fitting Shock Absorbers. Towing Trucks.

Rain vision wind shield—see page 739. *Can be purchased of Modern Auto Repair Co., St. Louis, Mo.



Third Brush Adjustment.

Turn 3rd brush plate adjusting screw in rear of generator just below fuse (fig. 2), in anti-clockwise direction for greater charging rate. This moves brush in direction of rotation. To decrease, move screw clockwise, see also pages 370, 924.

Shunt Field Fuse.

The fuse (fig. 2 above and page 370), is located on the outside of the commutator-end housing of the starter-generator is inserted in the shunt field circuit; and is designed to blow if the battery circuit is opened, thus protecting the system by rendering the starter-generator inoperative.

Therefore, if the machine fails to charge the battery at any time, inspect the fuse first of all; and, in case it is found blown, replace it with a new one. If the new fuse in turn blows as soon as the machine is started up, make a careful search for the cause of the trouble before running generator again.

Removal of Armature.

1—Remove four nuts on sprocket end of generator and pull plate off with armature; 2—undo pinion sprocket nut and pull pinion off; 3—remove bearing back of sprocket, which comes off when the armature is driven out of the plate. The front armature bearing is lubricated automatically from the chain.

To Remove and Replace Chain.

1—Remove housing enclosing starter-generator pinion; 2—turn engine over until master link is exposed; 3—break master link and attach both ends of new chain to old chain; 4—crank engine over until new chain is in place, when old one may be removed and master link of new chain closed; see also pages 411, 369 and 728.

To Adjust Chain.

See page 369 and illustrations, fig. 1, below and pages 411, 728.

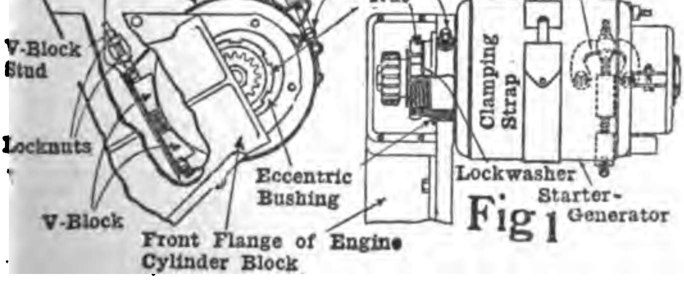
Oil Adjustment.

1—Oil gage on dash should show pressure of 2 to 4 lb. at 20 m.p.h.; 2—if pressure is too low or too high and investigation shows that adjustment is required, then remove spring in by-pass located directly in front of the water pump, stretching it for more pressure or cutting it off to give less pressure.

To determine whether oil is flowing through feed pipe inside crankcase when gage does not work, it is best first to remove oil inspection plug just beyond the lower rear corner of the rear valve cover plate. If oil spurts out at this point with engine running it shows that trouble is in the gage.

Carburetor Care.

To clean metering pin, undo bottom nut on carburetor (page 178), withdraw pin and wipe off with a rag moistened with hydrochloric acid.



If air valve sticks, the air valve stem may be dirty. move carburetor mixing chamber and bottom flange and unscrew the two parts of the valve. When apart, wipe stem, or neck of air valve which slides in a guide in the body of carburetor with a rag, moistened with hydrochloric acid. **Adjustment of carburetor** is explained on page 178.

CHART NO. 296—Dodge Starter-Generator Adjustments—see also pages 396, 370, 924. For a justment of Dodge Clutch, Brake, Rear Axle, etc., see pages 931, 932, 666, 689.

Fig. 1—A simple method for inserting screws in inaccessible places.

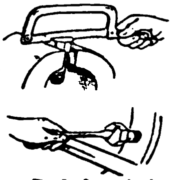


Fig. 2—Cut a slot in a cap screw head with a hack saw and use screw driver—to start cap screws in inaccessible places

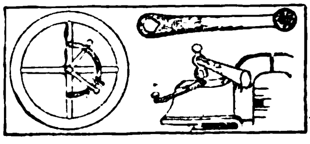

Fig. 3—Showing method for tightening a loose throttle control lever. Remove the lever from the car, place it on the anvil portion of the vise, strike it a few sharp blows with a hammer, as indicated in the illustration, whereupon, on refitting the lever to the end of the rod, instead of fitting loosely, it will be necessary to force it on by tapping it into place with a hammer; the nut then be replaced and the trouble eliminated.

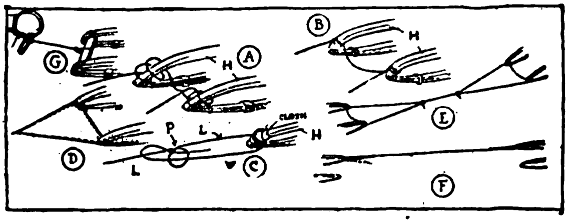
Two hack saw blades mounted side by side will cut a wider slot.



In fig. 2 are shown some right and wrong methods of securing the tow rope to the vehicle to be towed. The best way is shown at G, a piece of wood being tied under and across the frame horns as illustrated, and a single rope connecting it to the rear of the towing vehicle.

To loop the rope under the frame as at D is very bad, as a severe strain would bend the horns inward.

The bowline knot is the best to use at all times as it is easy to make and as easy to untie; it is illustrated at C. In the same illustration, attention is called to the cloth wrapped about frame to prevent chafing.

When a bar of wood is not readily obtainable, and a heavy car is to be towed, the rope may be secured as illustrated at B; two half hitches being used, as shown at A, to secure the rope to the horns of the frame, and the rope between the two horns being left slack. When using this method, the bights also should be as long as possible. Two long bights are shown at E; whilst an undesirably short bight is depicted at D. A shows how the two half hitches are made, and B shows how they look when drawn taut, the slack being shown in the rope between the horns H to prevent their being drawn together.

The knots at A and C are the most useful. Their advantage over other knots is that they will neither slip nor jam.—From Motor Age.

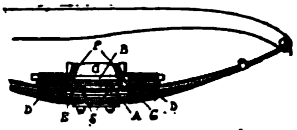


Fig. 3—A temporary spring repair: In fig. 3 is shown how a temporary repair was made upon a spring whose three lower leaves were broken on striking an apparently shallow hole in the road which was filled with water. After the break A occurred, the car was slowly driven to the next farmhouse, where some 2 by 4 blocks, a saw and some baling wire were obtained. The short block E was cut off first and two shallow grooves S were cut into one side of it so that it would clear the spring clips and rest flat on the central portion of the top spring leaf. The sides of these slots were cut with a saw and then finished up with a cold chisel carried in the tool kit of the car. The piece B then was cut off and nailed to the short piece E, so that the sides were flush and its ends extended over the ends of the short block equally distant on either side. The top block C, which was made just a trifle longer than the short bottom block, was cut off and slotted in the same manner as the under block, only the slots were not so wide and farther apart as designated by the letter F. This block then was nailed to the long piece, centrally located with the slots up. The frame of the car was then jacked up so that the injured end of the spring was a little above its normal height, and the blocks were set in position as shown and securely bound into place with the wire D. When this was done a few strands were wound about the two top pieces, as at F, to add to their security; then a few more strands were bound laterally around the whole, as at G. This completed the temporary repair.

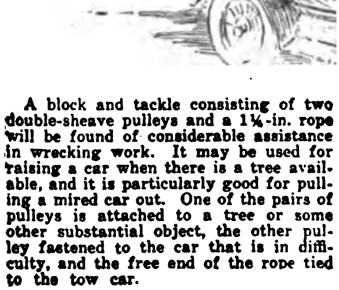
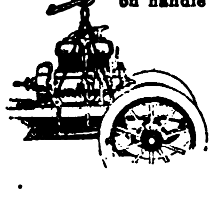


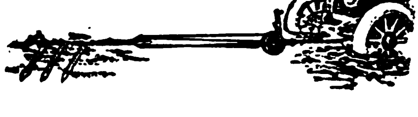
A block and tackle consisting of two double-sheave pulleys and a 1¼-in. rope will be found of considerable assistance in wrecking work. It may be used for raising a car when there is a tree available, and it is particularly good for pulling a mired car out. One of the pairs of pulleys is attached to a tree or some other substantial object, the other pulley fastened to the car that is in difficulty, and the free end of the rope tied to the tow car.

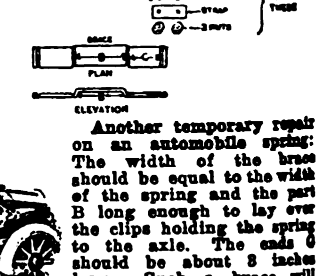


*The Pull-U-Out is a very powerful and satisfactory device for pulling cars out of mud holes, something indispensible when touring. This device is suited for a number of purposes. In addition to a "pull-out" it can be used as a hoist and many other purposes.

A pressure of 80 lbs. on handle will lift 1 ton. An ordinary block and tackle would require 176 lbs. pressure.

Address Pull-U-Out Co. 2018 Market St., St. Louis.





Another temporary repair on an automobile spring: The width of the brace should be equal to the width of the spring and the part B long enough to lay over the clips holding the spring to the axle. The ends C should be about 3 inches long. Such a brace will effectually repair either a front or rear spring.

CHART NO. 297—Miscellaneous Repair Hints. Towing a Car. Temporary Spring Repairs.

*The Pull-U-Out has advantages over the old-fashioned block and tackle, being lighter and more powerful. Can be used for hoisting as well as pulling. Pressure of 80 lbs. on handle will lift one ton. A triplex chain block would require 82 lbs. and an ordinary block and tackle 176 lbs.

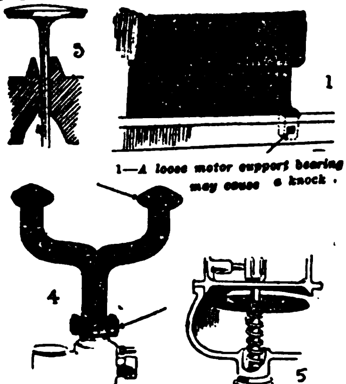
***How To Operate a Gasoline Torch—single jet type.**

Fill about ⅔ full of gasoline; filler plug on this type is at bottom of tank (A). The torch is turned up side down, gasoline poured in and plug screwed up tight, being sure it does not leak.

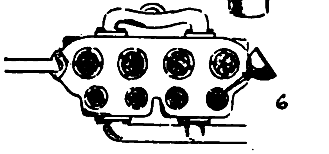
Air is then pumped into tank (A) by air pump plunger (P), being sure gasoline valve (V) is closed. Then hold hand over mixer tube (M) and slowly open valve (V)—gasoline will drip into heater (D). Light this gasoline with valve (V) closed. This heats the pipe (R). After the gasoline in heater (D) has burned up, the heat should be sufficient to vaporize the gasoline causing air and gasoline to flow through pipe L & R from tank (A) to burner or mixer (M) when valve (V) is opened. A match is applied to this mixture and should be blue in color—if yellow then heating is not sufficient and operation must be repeated. It is advisable to protect the flame from wind when heating.

All torches work on the same principle. Some, however have two valves, as per page 711, fig. 1, which is termed a "double-jet." They are also constructed with pots over the flame for melting lead in, these are termed "fire pots."

For brazing a similar principle is used except a larger tank and burner and separate air pump which pumps 75 lbs. into tank—see page 712.



1—A loose motor support bearing may cause a knock.



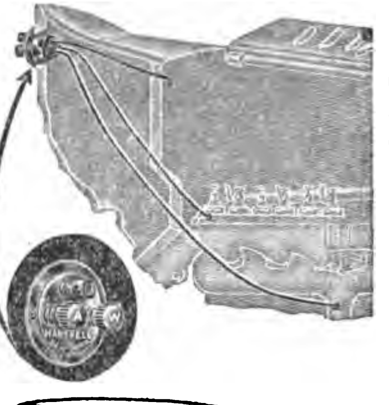
Common Cause of Misfiring

3—A worn valve guide leaks oil and permits extra air to be sucked into the cylinders.
4—A turned or broken gasket may cause an air leak.
5—A sticking air valve will cause misfiring and perhaps backfiring.
6—The cause of misfiring may often be traced to leaky cylinder plugs.

A Carbon Remover and Water Injector.

Fig. 12—This device, it is claimed will remove carbon by injection of steam into inlet manifold which loosens the carbon and permits it to be blown out the exhaust. It also admits air directly into the combustible mixture, which means more complete combustion or power.

It is often desired to paint or repair a top without leaving the car in the repair-shop. A simple support that permits this is a rectangular wooden framework notched to hold the top irons. The top is placed on this framework.



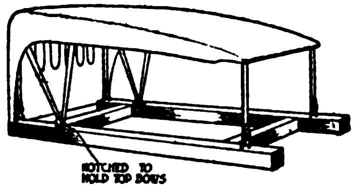


Fig. 20—A tank for testing inner tube leaks for tire repair shop is shown to the left. It is 6 ins. wide and 8 ins. deep.

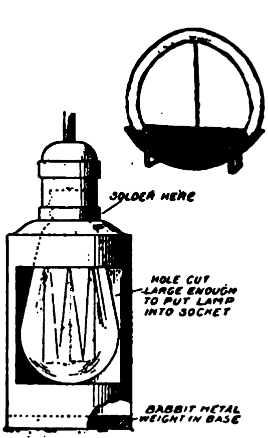
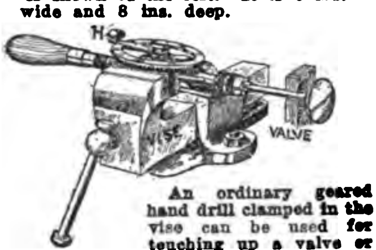
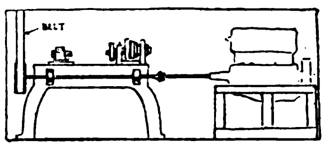


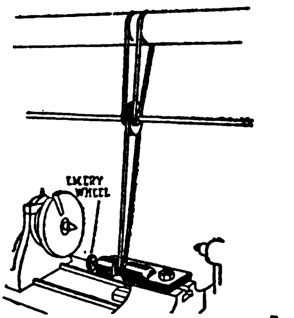
A shop light, made of a can protects the globe and not easily turned over.



An ordinary geared hand drill clamped in the vise can be used for touching up a valve or filing a taper pin when a lathe is not available. A wood "rest" or steadying piece must be placed behind the valve. It can be fixed by a screw or clamped to the bench.

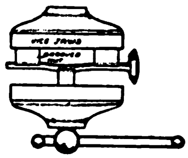


For "running engines in" after they are overhauled the simplest arrangement is probably to connect the front end of the crankshaft to a shaft driven by belt from the line shafting. This coupling may be of the starter crank type. The engine should be supported on a low stand and the driving shaft should be provided with a universal. The shaft is most simply mounted by bolting it to the legs of a lathe or planer, as illustrated, and the shaft is driven directly from a pulley on the line shafting. (see also Ford Supplement.)



A very small grinding wheel for mounting in a lathe may be used for fine work. The wheel is approximately 1 in. in diameter and runs several thousand revolutions per minute, this speed being obtained by a double belt reduction from the driving drum. The intermediate pulley really floats in the air, the shaft it slides on being merely to hold it in case one of the belts should break, thereby destroying its equilibrium.—

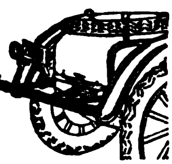
Home made valve spring lifter.



Method of straightening a bent shaft or rod such as a valve stem. The vise is used as a lever. The supports are grooved and adjusted to suit the bend.

CHART NO. 298—Miscellaneous Shop Hints.

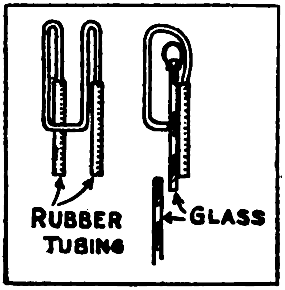
*See pages 711, 712 and 696 for a gas heater. Write Chicago Solder Co., 218 N. Union Ave., Chicago, Ill., for self-fluxing wire solder.



A bumper in the rear as well as the front is now the approved method. The Emil Grossman Mfg. Co. of Bush Terminal, New York, manufacture the bumpers for the rear or front. Write for catalog.

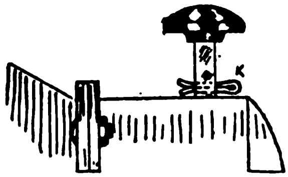
GOOD WINDSHIELD CLEANER.

One of the essentials of bad weather driving is some provision for keeping the top glass of the windshield free from snow or rain. Chemical preparations are sometimes used to give the surface of the glass a greasy surface, so that the rain will run off rapidly, but this method is not effective against snow. Scraping off the surface of the glass is perhaps the most effective method yet devised.



A simple cleaner may be made of a piece of rather heavy steel, or brass, wire about a quarter of an inch in diameter, and a piece of rubber tubing. The wire is bent in the form of a double loop, and a piece of rubber tubing is slipped over each free end of the wire. If the wire is coated with rubber cement, before the rubber tubing is pulled on, there will be no chance for the tubing to come loose.

The middle of the wire loop should rub on the inside of the glass at a point about opposite the middle of the rubber tubes, so that an even pressure will be exerted by the rubber tubes over their whole length on the surface of the glass. (Fordowner.)



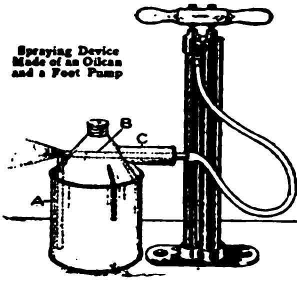
Silencing Mechanical Horns.

Car owners are often annoyed by small boys who persist in sounding the mechanical horn when the car is left unattended. A simple, but effective, method of discouraging this practice consists of drilling a small hole through the plunger rod and slipping a cotter pin through this hole when the car is left alone.

While the cotter pin may be easily removed when the owner of the car returns.

Window Cleaner.

For removing dust from windows the ordinary rubber edge window dryer combined with a nozzle which gives a flat spray the full length of the edge, may be used with a considerable saving of time. The nozzle is made from a piece of copper pipe, which is flattened and flared, as shown, and is then strapped to the handle. The water is turned on and the tool is rubbed up and down the window surface, thus removing all dust and dirt; then the water is shut off and the window is dried by scraping the drops away—



Painting an Automobile Radiator

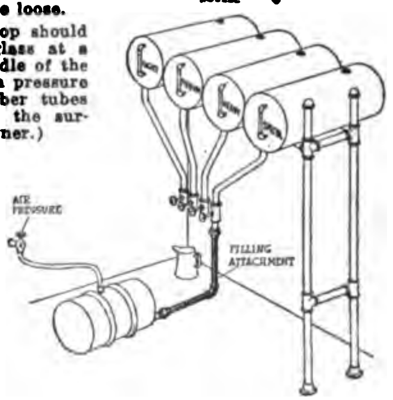
Painting an automobile radiator quickly and thoroughly with a brush is difficult. A homemade spraying outfit similar to the one shown in the illustration made the job easy.

The outfit consists of a ½-gal. oilcan, made into an atomizer by attaching a tire pump to the end of the air pipe B. A piece of small brass pipe. A, was mounted in one side of the can, the upper end of it extending a short distance outside of the top. A second piece of pipe was mounted in a horizontal position in the top of the can, as shown at B. If a handle is attached to the can, as at C, the piece of pipe B may pass through it lengthwise and extend a short distance beyond the end of the handle. Both pipes were soldered to the top of the can, and the screw top was provided with a gasket to make it tight.

When the air is forced through the horizontal tube B and caused to pass across the opening in the upper end of the vertical tube A, the liquid in the can is drawn up and forced out in a fine spray. A mixture for spraying the radiator may be made of lampblack and turpentine. A sheet of paper should be placed back of the radiator to protect the engine, and around the outer edge, to prevent the liquid from bespattering the brass finish.

STEERING POST PULLER

Two wooden blocks clamped to the steering post by a heavy metal clamp offer a convenient brace for a jack, thus permitting the removal of the steering post. After applying a strain to the post by means of the jack, a few blows on the blocks with a heavy hammer so loosen the post that it may be drawn out without injury.—



OIL STORAGE SYSTEM

An oil storage system whereby the oil is discharged by gravity, is shown. It comprises several tanks, as many as there are kinds of oil to be stored, held close to the ceiling on pipe standards, and each pipe connected to its discharge valve. Oil is transferred from the original barrel by air pressure, through a special connection, in the manner illustrated. In addition to facilitating the withdrawal of oil, this method gets the storage tanks up out of the way, and saves much valuable room.—

Rough surfaces, such as garage walls, may be painted or whitewashed quickly and economically by the use of an air spray similar to that used for cleaning motors with kerosene. The paint or whitewash is placed in a bucket and the application of air pressure to the nozzle, whose construction is plainly shown, atomizes the liquid and sprays it against the walls. Valves are provided for regulating both air and liquid flow, and with a little experience it is easy to obtain an adjustment which will allow an even and economical application of paint.—

*Testing Circuits.

The test of electric circuits is simple if one will divide the electric system into units (see also, page 416)—For instance:
(1) Starting motor circuit.
(2) Generator circuit.
(3) Lighting circuit.
(4) Ignition circuit.
(5) The storage battery.

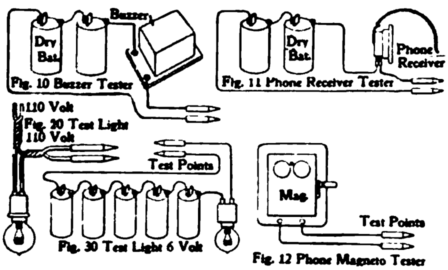
Electric troubles may be in the major parts, as motor, generator, lamps, timer, battery, or **in the wiring connecting parts.**

There are four classes of electrical troubles, namely: an open circuit (page 415); a short-circuit or a ground (page 412), and a poor connection.

The idea then is to start testing at the proper point of the circuit after diagnosing the trouble as explained at the top of page 577. For instance, if starter trouble, start at the battery, then switch, then interior of motor, then back to battery. If generator trouble, start at the generator. If lighting trouble, start at the light switch, then fuse, then wiring, then lamp. If ignition trouble, start at the ignition switch. If battery trouble, start at the battery.

**Circuit Testing Devices.

Circuit testing devices can be divided into two general classifications: visible and audible.



Visible circuit testing devices would include test lights as per figs. 20 and 30, and the ammeter and volt-meter per pages 410, 416.

Audible circuit testing devices would include an electric bell or buzzer (fig. 10), a phone receiver (fig. 11) or a telephone magneto (fig. 12).

The test light can be either a high voltage light from a lighting circuit, as a 110 volt circuit (fig. 20), or a low voltage lamp used with a storage battery as per page 418, or a low voltage lamp with dry cells per fig. 30 above. See pages 418, 403, for tests which can be made with a test light. If a 110 volt lamp is used, then a carbon filament lamp will stand more vibration than a Tungsten lamp. Five cells and a 6 volt lamp will probably be more convenient than the storage battery, as it can be moved about more readily.

The ammeter and voltmeter can be used in many instances where a test light can be used and vice-versa—see pages 416, 410.

The buzzer or bell and phone receiver (figs. 10 and 11) has the advantage that both hands can be used with the test points, especially when testing out different sections of the armature coils. Two dry cells are sufficient.

Test points are explained on pages 399 and 418. The points can be made of steel about 6" long with sharp points so it will make good contact

The magneto tester (fig. 12) generates a high voltage and is adapted for tests which will force a current through a high degree of insulation as poor connections or a leaky path and coil windings. This device is nothing more than a telephone magneto generator with a bell, test cords and test points. It is cranked by hand.

Dynamo and Lines of Force.

Question: How does a dynamo start to generate current when there is no magnetic influence to start with to build up "lines-of-force." On page 267 the explantion is that a magneto starts to generate current because the "permanent" magnets produce lines-of-force.

Answer: The field poles of a dynamo are not permanent magnets as they are soft iron. Permanent magnets are made of steel. Soft iron however, will retain a small amount of magnetism. When generator was constructed it was first run as a motor, which gave it the initial magnetism, due to current flow around the wire wrapped around the field poles, thus producing "electro-magnetism"—see page 325. A slight amount of magnetism is left in the poles and always remains there, called "residual" magnetism. Therefore when generator armature is driven as a generator and field circuit is connected to the brushes, even though the residual magnetism is very slight, there is sufficient lines-of-force for generation or production of e. m. f. at the brushes, and as the armature revolves in this ever so weak a field the lines-of-force are cut and the e. m. f. builds up as the speed increases causing current to flow through the field winding and is thus "electro-magnetized" stronger and stronger.

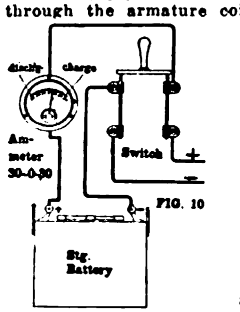
It is advisable when overhauling a generator to run it as a motor after repairing—see page 424.

The above generator generates alternating current just the same as a magneto, but the **commutator** is arranged so that the polarity is kept definitely positive and negative at the brushes or "direct" current.

Loose Commutator Connections.

One can tell if generator is generating its proper output by observing the ammeter. One should learn just what the maximum output should be. If it generates a very low amperage, say about 2 amperes, then at times none at all—the trouble may be due to a loose connection and sometimes that loose connection is at the point where the end of armature coil is soldered to the segment; which, although apparently securely soldered may be loose.

One method of testing, is to use a test light and test points—place one test point on commutator segment connected with the suspected loose armature coil and the other on the segment 180° apart, or on extreme opposite side of commutator which is the other end. If on passing the current through the armature coil in this manner, there will likely be a slight spark or arc at the point where loose—test all segments in like manner and resolder any that are loose.



To Find Polarity of Rectifier.

The charging wires from a rectifier, if connected wrong (use a regular dash type ammeter) will show 30 amp. If connected correctly will show about 6 amp. (Motor World.)

CHART NO. 300—Useful Information For The Electrical Repairman. See also, page 429.

*It is advisable to obtain a Wiring Manual—see adv. back of book. **For testing open circuits, short circuits, grounds, armature and field coils per pages 402, 403, 418, 577. (Motor Age.)

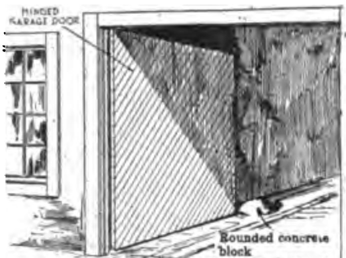


Fig. 30: This Concrete block will save backing and driving into door.

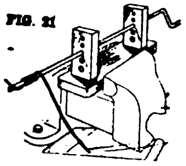

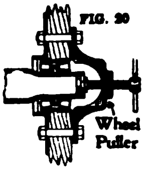

Fig. 21. Spring Winder.

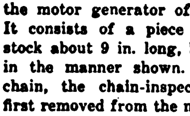
Springs of various sizes may be wound on the spring winding outfit illustrated. A cast-iron frame supports two uprights that act as bearings for the spring winding spindle. These spindles are tool steel rod, having a diameter somewhat smaller than the inside diameter of the spring to be wound. One end is bent to form a crank and handle, the other being notched to receive the spring wire.

***Fig. 20. Rear Wheel Puller.**

A special puller is required for the removal of the Dodge rear wheel. After the removal of the outside flange and the rear axle, the frame of the puller is bolted onto two of the flange bolts. The plunger on the end of the screw fits inside the rear axle, housing, giving a leverage that permits the ready removal of the wheel. The frame is made of cast iron, reinforced by ribs; the screw is a ¾-in. bolt.



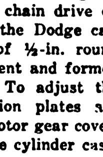


Fig. 22. Generator Spanner Wrench.

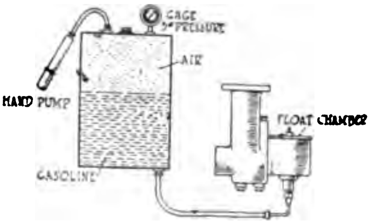
A spanner wrench for facilitating the adjustment of the silent chain drive on the motor generator of the Dodge car. It consists of a piece of ½-in. round stock about 9 in. long, bent and formed in the manner shown. To adjust the chain, the chain-inspection plates are first removed from the motor gear cover Then the set-screw on the cylinder casting and the strap holding the motor to the hand hole cover plate are loosened. By means of the spanner wrench the eccentric bushing is turned until the chain has the proper tension. When properly adjusted the chain should run without perceptible noise.-

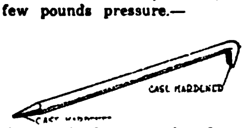
Fig. 24. Generator Gear Puller

A puller for removing the generator gear on the Dodge car is shown. The housing is made of cast iron, cut away at the base to engage the gear and provided with a ¾-in. set-screw for obtaining a leverage on the generator shaft.

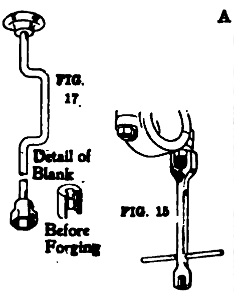


FLOAT VALVE TESTER

This illustration shows a device for determining whether the float valve of the carbureter leaks. It is designed particularly for pressure systems, although it may be used for the ordinary gravity system by simply removing the pressure. It consists of a tank partly filled with gasoline and provided with an air gage and hand pump. The carbureter is attached, the pressure raised to the required amount, and then the carbureter is allowed to stand for several hours to determine whether any leakage takes place. Float valves which may not leak at all when tested under a small gravity head, will leak badly when put under a few pounds pressure.—



A pinch bar 18 in. by ⅝ in., handy for removing gears, etc.



A Shellac Bottle.

No. 17. Crankcase Wrench.

The retaining nuts on the crankcase may be quickly removed or replaced by the aid of this wrench. The handle is made of ½-in. round stock bent in the form of a bit-stock, as shown. The upper end is fitted with a hand rest; the lower end with a socket for engaging the nut. A short piece of round stock, slightly larger in diameter than the nut to eventually be turned, is drilled, as illustrated in the smaller sketch. It is then heated and formed over the nut it is to fit, casehardened and secured to the handle by a pin. —

Fig. 15. Crankshaft Bearing Wrench.

It is often difficult to get a socket wrench thin enough to fit between the nut and the bearing housing of the connecting-rod or crankshaft bearing. Or if thin enough to do this the wrench is too weak to properly tighten the nut. A solid S-wrench may be used, but is not as satisfactory as the socket for this purpose. A solid socket wrench, cut away in the manner illustrated, possesses the required strength and has all the advantages of the full-socket wrench. As the connecting-rod nuts are not the same size as the main bearing nuts, the wrench should be made double-ended and fitted with a removable handle.-

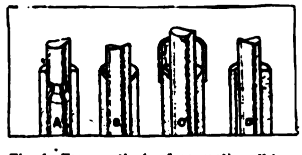


Fig. 4—Four methods of preventing oil loss from valve tappet guides

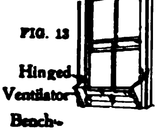
Many engines lose oil from the tappet guides, and in Fig. 1 are four methods of dealing with this nuisance.

In method A the tappet itself is doctored, a groove being ground in the center This groove is of peculiar design, the upper portion being sharp cut and the lower part gradually chamfered, the idea being that the oil escaping past the rounded portion is met by the sharp edge when the tappet is descending, and is forced down with an action similar to the scraper ring on a piston.

In B a deep recess is countersunk in the top of the tappet guide, and forms a slight well where oil can accumulate. If there is still a tendency for the oil to overflow, the idea can be carried a step further, and we arrive at Fig. C, where the well has been increased by soldering to the top of the guide a collar made from a piece of brass tube ⅛ inch in depth and of such diameter as to be just slipped over the head of the guide.



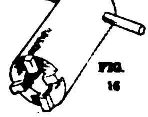


Fig. 13. Window Ventilator

Some method of ventilating the repairshop should be provided, and a simple form of window ventilator is shown. It consists of a piece of an old windshield glass, held in an inclined position on the window sill by two triangular supports, and permits the window to be raised and the shop ventilated without causing a serious draught on the mechanic.-

Fig. 16. Valve-Cap Wrench.

A wrench for removing slotted-head valve caps may be made from a bar of steel 2 in. round and 6 in. long. A ¾-in. hole is drilled through the center of the piece and the jaws filed on the lower end, as shown. A transverse hole drilled in the upper end permits the insertion of a bar ½-in. round for a handle. The threads of the cap should be smeared with a paste made of graphite and oil before replacing the cap.—Hudson

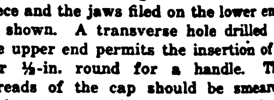

Fig. 14. Valve Tappet Adjustment.

The valve tappets of the Maxwell may be readily adjusted by means of special wrenches provided for that purpose. Two standard 626-X check nut wrenches are purchased at any supply store, and bent, after heating, in the manner shown. After loosening the lock-nut the adjusting screw may be turned until a gage registers the proper clearance. This should be from .006 to .009 in.—

CHART NO. 302—Miscellaneous Repair Shop Hints. (Motor World.)

Charts 301 and 303 omitted (error in numbering). ** See page 742 for Buick wheel puller.

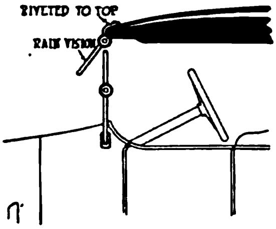

Fig. 6—Rain vision windshields are common on closed cars but unusual on open ones. It is a simple matter, however, to add this feature. The upper section of a windshield is mounted on the front of the top, two specially made brackets being used to hold it in place. It catches the rain and the regular windshield protects the driver from the wind.

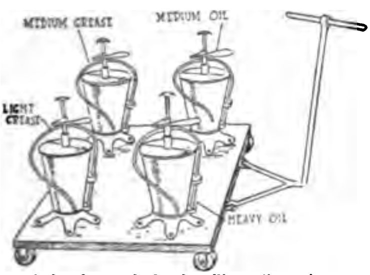
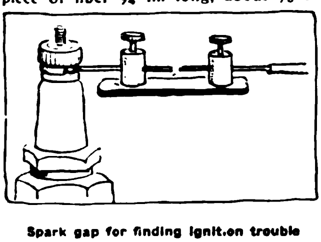


A handy truck for handling oils and grease either in the service station or garage may be made by building a small wooden truck mounted on castors and placing on it small tanks equipped with self-measuring pumps. In the device shown the Weaver bucket pump is used. The self-measuring feature enables the oil and grease to be sold at the curb or in the garage in the same way that gasoline would be from a wheel cart.—

Ignition Tester

To find which cylinder is missing, a piece of fiber ¼ in. long, about ⅛ in.



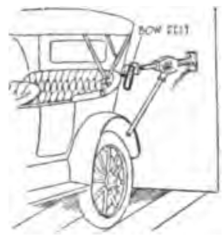
Spark gap for finding ignit.on trouble

thick and ¼-in. wide is taken, and near the ends are inserted cable terminal posts. Through each post is passed a copper wire, the ends at the center being adjustable through lateral movement of the wires. One of the wires has a loop at the end for attachment to a plug. The ignition cable is attached to the other post. With one of these on each plug and the wires at a varying gap, it is possible, especially in a dim light or darkness, to see the action of the plugs.

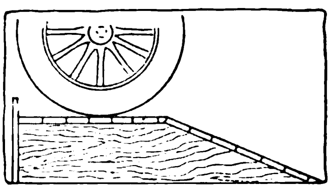
Fig. 1—Listening for rear axle hums; the hands are placed in front of the ears to intercept the sounds

Various Axle Hums Defined

The adjustment of axle gears can best be determined by sitting in the rear seat and holding the hands over the ears (Fig. 1). Should the sound from the axle be a steady hum and not too loud the gears may safely be said to be adjusted properly. If, however, there is an occasional stress in the sound, that is, a steady hum interrupted with a rather loud note, the adjustment may be incorrect. It will be found in testing in this manner that the gears may sound well when the car is running at uniform speed, slow or fast, but that as soon as a pick-up is desired a stress in the sound will be heard. Then again the gears may sound well except when coasting, which is another ailment which may be corrected by adjustment. If after trying various adjustments, perhaps taking in the whole range, the gears still give a characteristic loud note at intervals, it may be that one or more teeth are broken or the gears are slightly out-of-round.



Many times an ordinary jack may be used to advantage in straightening bent parts. For example, one of the rests for the top bows was bent in a slight accident and it was quickly straightened by backing the car up close to the garage wall, as shown, and using a jack.—

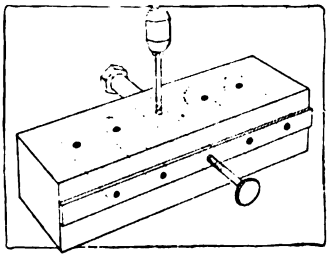


Box Substitute for a Pit.

While not new, the substitute for a pit illustrated is worth describing because of its merit. Two heavy wooden boxes, one for each wheel, with a slope of about 30 degrees, and a flat space on top are used. The boxes are constructed of 1½- or 2-inch planks; the height is about 10 inches and the length about 4 feet. Such boxes will support even a heavy car.

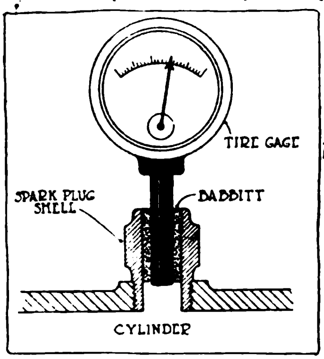
Jig for Cotter Holes.

A jig for drilling cotter pin holes in bolts and pins may be made of a piece of square stock in which there are several transverse holes for receiving various sizes of pins. At right angles to each one of these is a hole through which the cotter pin drill is inserted. The distance that the cotter hole is from the end of the pin is determined by the adjustment of a stop screw which is carried in a plate in the back.



Compression Tester.

A compression tester is necessary for accurately determining the condition of valves and pistons as regards their tightness. A cheap but satisfactory one may



Compression tester made of tire gauge and spark plug shell

be made by combining a tire gauge and a spark plug shell. The gauge may be fastened to the shell by pouring babbitt or lead in between the two or a special reducing nipple may be used. The gauge, of course, is placed in the spark plug hole when a cylinder is to be tested. A weak cylinder can be readily indicated even if the normal compression in pounds is not known, by the fact that it will register less than the others. The use of this device is very important; it should be employed whenever any irregularity is noted in the operation of the motor. Leaky valves, pistons and valve stem guides may cause a miss or a jerky action that ordinarily would be blamed on the carburetor or ignition.

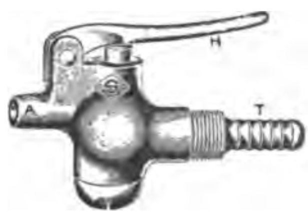


Fig. 4—An automatic blow cock —used in connection with an air storage system for dusting out cars, cleaning engine and parts. T—connects with air line. H—handle. A—blower opening. (Stevens Co., N. Y.)

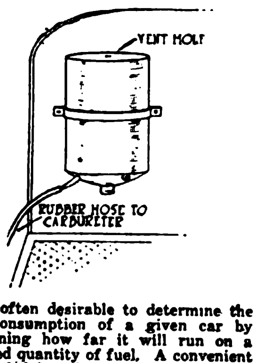
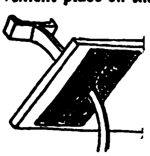
When quoting prices on repair work it is advisable to keep a statement of work necessary, marking after each item the cost. Keep original with owner's signature and give copy to him.

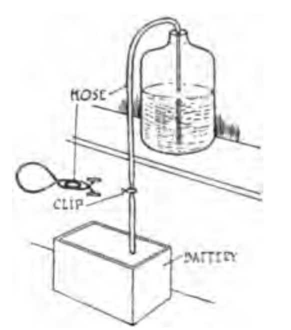
Extra equipment: include here the tools left in his car, then there can be no dispute. Put them in stock room. This plan can be elaborated upon—see also page 600.



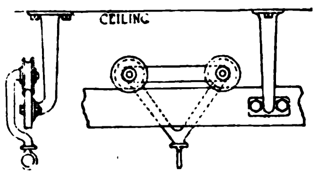
It is often desirable to determine the exact consumption of a given car by determining how far it will run on a measured quantity of fuel. A convenient means of doing this is to take an ordinary ½-gal. kerosene oil can and place in it a quart of gasoline. A rubber tube running to the carbureter is then attached to the spout and the can is inverted and tied securely at some convenient place on the motor or dashboard.



A cold draft preventive—a piece of sheet rubber placed as shown.

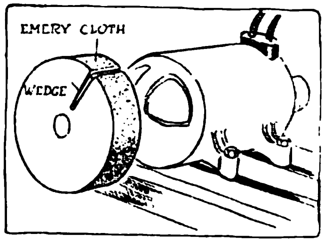


The principle of the syphon may be used in many places in repairshop work. For example, it provides a simple method of drawing distilled water for the storage batteries. A glass tube extending to the bottom of the bottle is inserted in the cork and a rubber tube is attached as shown. The end of the glass tube must extend below the bottom of the bottle, consequently it is advisable to place it on a shelf. The tube may be made long enough to reach to the storage batteries. The flow of water is controlled by a simple spring device which pinches the tube. This may be made, or purchased at a drug store. To put the syphon in operation it is merely necessary to suck on the tube until it is filled with water. Once this is done the water will remain in the tube and the syphon will always be ready for instant operation until the bottle is emptied. The same principle may be applied for drawing gasoline from a tank, oil from a crankcase, electrolyte from a storage battery, and is adaptable to many other uses. Of course, it is usually more convenient to drain a gasoline tank or crankcase in the ordinary way, but sometimes the syphon principle will be found quicker.

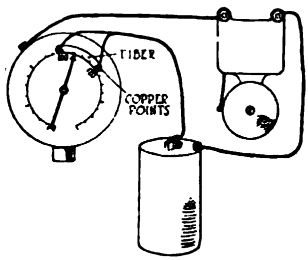


An overhead railway for repairshop use may be patterned after those in use in large butcher shops. It consists of a track made out of stock about ½ x 2 in. and suspended from the ceiling by arms at frequent intervals. On this track is placed a cap, to which the block and tackle is attached.—

A grinding wheel for doing special work can be made by attaching a wooden wheel to the electric drill and wrap-



ping a strip of emery paper around the periphery. The paper is fastened by cutting a notch in the wheel and holding the ends of the paper by driving a wedge into the notch.



It is a very simple matter to build a device which will cause a bell to ring when the pressure in the air tank reaches the desired maximum or minimum, thus reminding the man in charge that the compressor should be turned off or on. The indicating hand on the air gage completes a circuit by touching a metal pin when it moves to either extreme, and thus makes the bell ring. These pins are mounted in a small fiber block, which is riveted to the face of the gage. The two pins are thus completely insulated from the gage and are connected to one terminal of the bell. A short piece of wire runs from the other terminal to the battery and the return wire is attached to the casing of the gage, so that current flows through the casing and the hand to one or the other of these metal points.

Fig. 7—Another engine cleaner: Parts may be readily cleaned by a gasoline spray or aspirator, actuated from the air pressure line. This spray comprises a short length of copper tubing, about ¼ inch in diameter, having a piece of 1/16 inch brass tubing soldered onto its side. The air line is connected to the larger tube, and the smaller tube is connected to the gasoline supply. When the air is turned on, a suction is created in the smaller tube, drawing gasoline from the can, and forcing it onto the part to be cleaned. (see also fig. 5, page 744.)

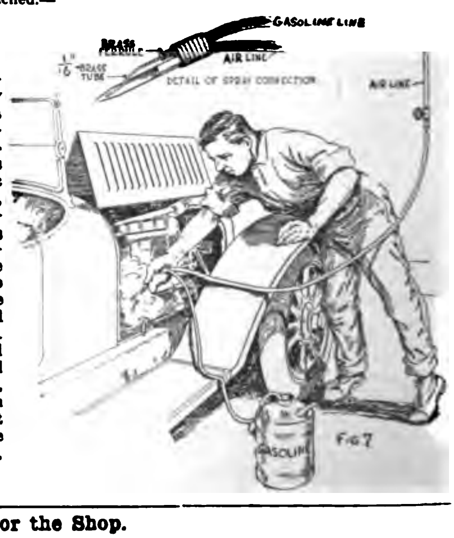


CHART NO. 305—Useful Devices and Repair Hints for the Shop.

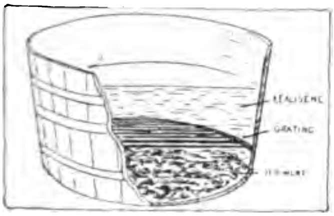
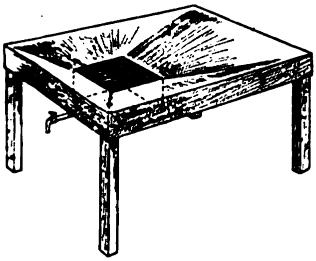
Kerosene Tub

A large tub of kerosene will be found convenient for washing parts. The tub should have a metal grating 4 or 5 in. from the bottom, so that whatever sedi-

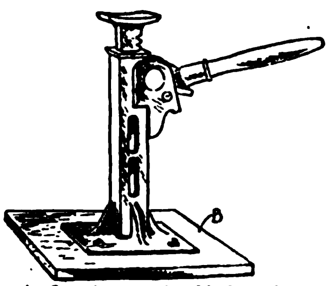


Kerosene tub with metal grating

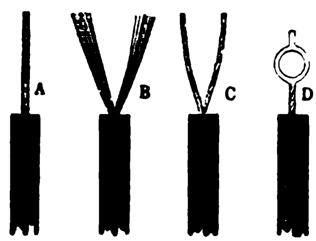
ment settles is not stirred up each time a part is washed. The presence of the grating insures clean liquid for a considerable length of time, for just as soon as a part is washed the grit and dirt settles below the grating, leaving the liquid clean.



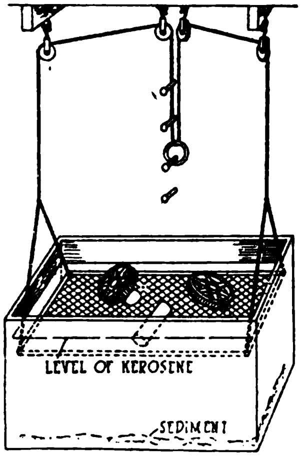
A roughly made table, covered with tin or zinc and with a well in it for holding kerosene, makes a handy arrangement for cleaning parts. There is a drain at the bottom for removing the sediment.



A flat block should be placed under a jack when used around a car to prevent turning over and sinking in the ground.



Four steps in making loop end: A, insulation removed; B, separating the strands; C, twisting wires into two leads; and, D, the looped end dipped in solder. (Motor Age.)



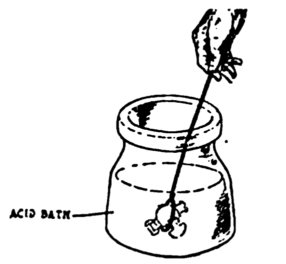
Combination cleaning tub and drainboard for removing the dirt from parts. It is usual to make the tubs and drainboard separate, but by installing a screen in the tank whose height may be readily raised or lowered, all the advantages of drainboard are obtained, together with considerable economy of space and some added conveniences.

Fig. 7.

Fig. 9—To assist in removing heavy truck wheels a simple skid can be made by placing a 2-in. board on top of a series of rollers made of old shafting or heavy pipe. Chocks are fastened to the board to prevent the wheel rolling.

Fig. 10—This is the "ball and spring" oil regulator, as explained on page 198. Note how the adjusting screw increases tension on spring through the part (C). Dirt beneath this ball (B) check valve will cause a drop in pressure, and may be removed by snapping the ball (B) up and down a few times with a piece of wire (W) inserted through the oil passage.

Fig. 16—To remove wheels from a truck axle when stuck or rusted on.



Cleaning Brass Parts.

Small brass parts, such as pet cocks, carburetor parts, etc., may be made to look like new by dipping them in the following bath; Nitric acid, 75 parts; sulphuric acid, 100 parts; lampblack, 2 parts, and salt, 1 part. This solution should be mixed and kept in an earthenware or glass jar, and the parts should be thoroughly rinsed and dried after dipping—(see also pages 401 and 508.)

No. 7—Gasoline, or kerosene, forced by air pressure onto the parts to be cleaned, quickly removes all dirt and grease. A system for doing this is illustrated. The cleaning liquid is held in a metal tank placed beneath the inclined cleaning troughs in the manner shown. An injector type nozzle, connected to the air line and to the liquid, permits the liquid to be drawn from the tank and forced onto the part to be cleaned, after which it drains back to the tank to be used over and over again. During the periods that the cleaning outfit is not in use the dirt settles to the bottom and may be scraped out—see also fig. 7, page 740.

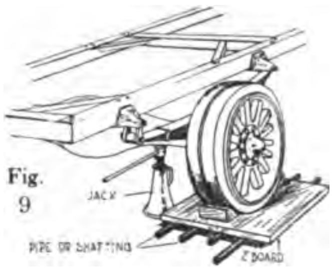


Fig. 9

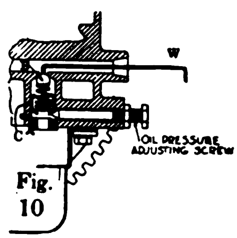

Fig. 10

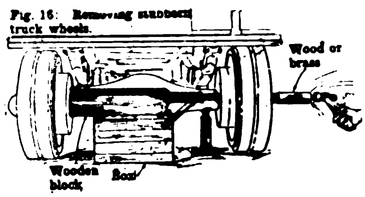

CHART NO. 306—Miscellaneous Shop Hints.

***When soldering wire connections** clean the wire with emery or sand paper, then twist the two wires together and use a non-acid flux where there is a high degree of insulation or soldering acid of a solution of zinc chloride will do. Then apply hot soldering iron—see also, page 711.

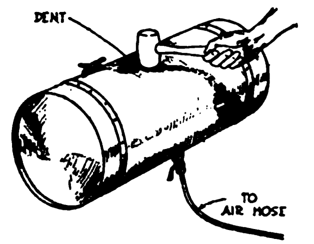

Fig. 17—A dent can be removed from a gasoline tank by plugging vent, filling with water and applying 20 lb. air pressure. A lead or wood mallet is used by tapping gently around outer edge of dent.

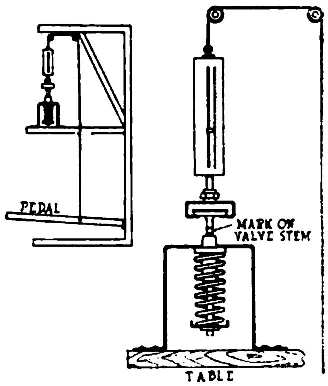

Fig. 2—When engine is overhauled, the old valve springs should be tested to see that they have not weakened, and whenever a new spring is put in, it should also be tested to see that it supplies the correct pressure. The illustration shows a simple means of determining whether a spring is in good condition or not. The apparatus consists of a bracket in which is mounted a valve guide, valve, spring, spring seat and retaining key. Two marks are placed on the valve stem, one indicating when the compression of the spring is zero, and the other when it has been compressed a certain amount, say ⅛ inch. The number of pounds required to compress the spring ⅛ inch may be ascertained by writing to the factory. When everything is in place, the pedal is depressed and the valve is raised until the lower mark on the stem is on a level with the top of the valve guide, at which time the pull as registered by the spring scales should be the amount called for by the factory.

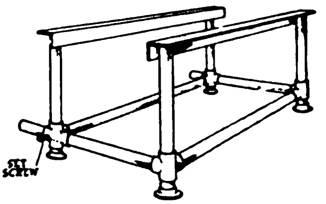

Except for the two angle irons, which carry the motor arms, this stand is made entirely of pipe fittings. The left member may be slid to the right or left to provide for motors of different widths This is possible because the horizontal openings in the cross-shaped pipe fittings are large enough to take the cross pipe. Set screws are used to lock the stand after it has been adjusted to the desired width.

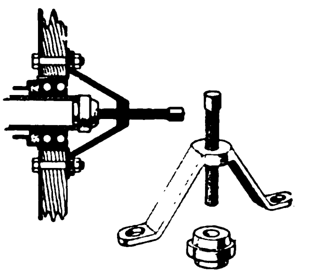

Fig. 2—Rear wheel puller: This puller is used to remove the rear wheels of the Buick. The wheel flange and axle are removed and the puller bolted to the flange bolts. A steel button is then placed in the rear axle tube, and the pressure applied by the central screw. By having several sizes of steel buttons, and making the flange bolt holes oval, this puller may be used on many cars.

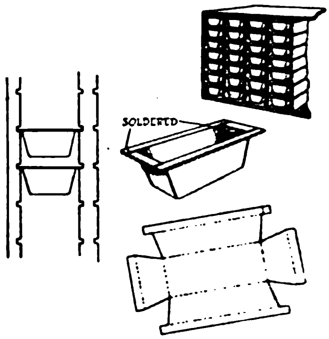

Small parts, such as screws, bolts, washers, nuts, gaskets and the like, are conveniently kept in tin drawers, as illustrated. The drawers are cut from a single piece of tin and are soldered, as shown by the heavy lines. The drawers slide in grooves cut in planks placed vertically. The grooves are made with a saw and chisel. The advantage of this method of storing parts is that the construction of the receptacles is very inexpensive and maximum convenience is afforded. It is possible to see what is in the various drawers without pulling them out, which is a feature peculiar to this design and saves considerable time when the exact drawer a certain part is in is not known.

A suggestion for making a hoist to raise and lower transmissions where considerable of this work is being done.

Speedometer Pointers.

When speedometer pointers vibrate—look for loose unions, connection, flexible shaft bent too sharp, lack of lubrication, gears not properly meshing.

Failure to indicate speed—look for same causes as above. Also for broken link in shaft.

Noisy; lack of lubrication or above causes. **(see also page 518.)**

To Put a Lamp Reflector in Condition.

When reflector becomes dull it may be polished or buffed. If plating is thin and will not stand buffing—the old plating must be removed and re-plated and polished by an electro plater. If a good heavy plating is put on, it can be rejuvenated and be practically new again.

Buick Spring Compressor.

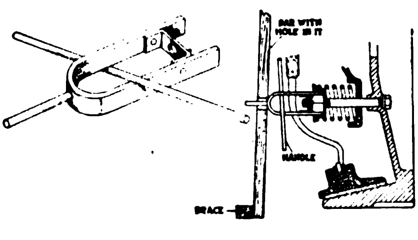

Fig. 4. Combined wrench and spring compressor: Though designed primarily for replacing the clutch bolt on the Buick D-28, this tool may be adapted to almost any job that requires a spring to be compressed before the nut is replaced. The wrench proper is a U-shaped piece of steel, bent to just fit the face of the nut, and held together by a cross strap. A rod, placed in the manner shown, permits a wooden lever to be used to compress the spring, after which a steel bar, stuck through the legs of the U is used to screw the nut in place.

CHART NO. 307—Miscellaneous Shop Hints. (Motor World.)

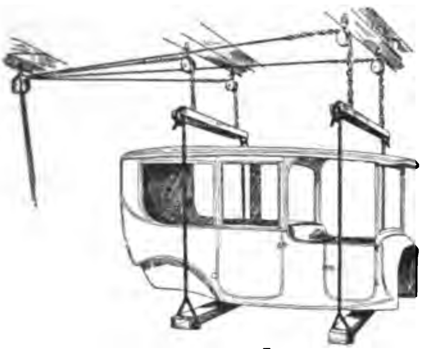

Fig. 1—Closed bodies may be removed without strain by the aid of the hoisting cradle illustrated. Two cross pieces are attached to separate chain hoists and are so spaced that they hang 2 ft. from the ends of the body to be removed. First one end of the body is pried up, and a lower cross-member slipped beneath it. Then the other end is raised, and the other lower member put in place. The steel stirrups are then used to attach the lower and upper cross pieces, after which the body may be raised and the chassis rolled from under.

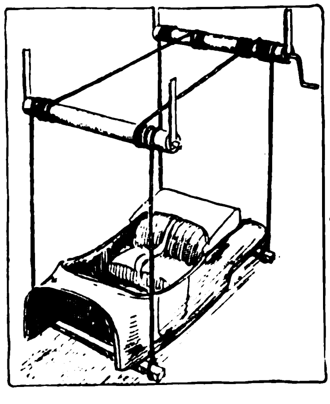

Turning one crank lifts all four corners of the car body at the same time

Fig. 2 — Another hoist for raising a body in the minimum time is illustrated. The body is supported by the hoist until the overhauling is completed, when the chassis is rolled back under and the body lowered in place again. The hoist consists of two 4-in. metal rollers about 5 feet long, one for raising the front of the body and the other the rear. These are suitably supported in a wood frame and are placed about 10 feet apart. The hoisting is done by a large crank attached to one of the rollers. All four ropes are wound around this sheave, and two of them run to the other sheave which is merely used as an idler. Seven-eights hemp rope is used. The body may be attached to the ropes by either fitting hooks to the rope ends or looping the ends of the repes and using two cross bars under the body, as illustrated.

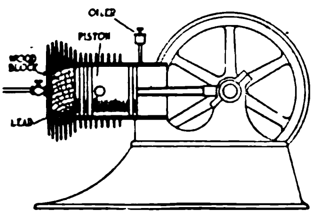

Fig. 6—A serviceable *air-compressor was made out of an old one-cylinder, air cooled stationary engine with very little work. In order to raise the compression pressure it was necessary to minimize the clearance between cylinder head and piston. This was done first by fitting a conical wooden block to the piston head and holding it in place with three ¼-in. cap screws. Then the space surrounding it was filled with lead. The intake valve of the engine is still the intake valve and the discharge valve is a ball check valve operating on a hard rubber seat in the discharge pipe, as close to the cylinder as possible. The exhaust valve opening was plugged up and all excess fittings were removed from the engine. The piston was fitted with step rings and a force feed oiler was substituted for a drip type. The compressor will fill a 16x48-in. tank to 158 lb. in 25 min. with a 1-hp. engine. The bore and stroke are 3½x3⅝ and the speed is 225 r.p.m. (Motor World.)

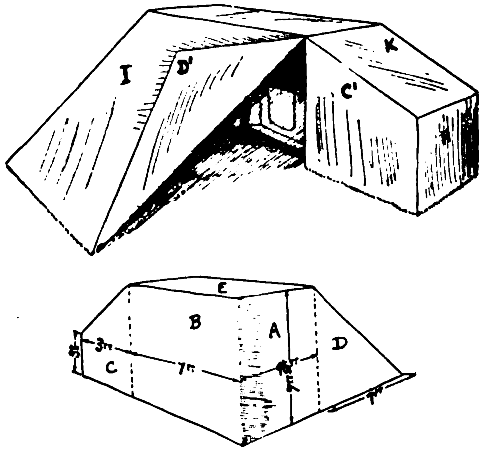

Fig. 8—A servicable tent for touring: Although this subject was fully treated on page 516, this being such a servicable outfit it is mentioned here as a timely suggestion, although out of place in this chart.

Use 8 oz. duck which comes in 36-inch widths and can be purchased at 20c per yard.

Dimensions of tent in square feet: A—4½'x 7'=31½'; B—7' x 7'=49'; C—3'x5¼'=15¾'; C¹—3'x5¼'=15¾'; D—7'x7'=49'; D¹—7'x 7'=49'; E—4½'x7'=31½"; H—4½'x3½'=15¾'; I—7'x8'=56'; K—4½' x 4½'=20¼'; Total 284½' sq. feet or approximately 31¾ yds. at 20c per yard making $6.35. (Motor Age.)

See page 541 explaining symbols of feet (') and inches ('').

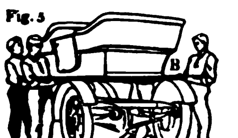

Fig. 5 — **Removing a** body: Showing how the body of a car can be easily lifted from or onto the chassis, and conveniently transported about the garage or shop.

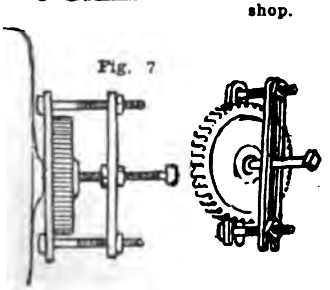

Fig. 7 — A gear puller for removing tight gear wheels. The illustration explains its construction and action. (also see page 606)

How To Run a Lathe.

"First Year Lathe Work" and "How to Run a Lathe"—price 10c each—supplied to readers of this book by the South Bend Lathe Works, South Bend, Indiana.

CHART NO. 308—Miscellaneous Repair Shop Hints.

***A motorcycle engine can also be utilized for a compressor.**

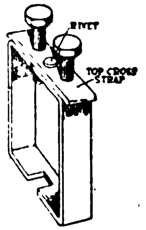

Fig. 1.

Fig. 1—This is a simple tool for compressing the clutch springs on the Reo when assembling the clutch. It is a strip of flat iron, bent into a square, and riveted together by a cross strip as shown. Holes are drilled and tapped at each side of the cross piece for the pressure screws. In addition to holding the ends of the top together, the cross strip also furnishes sufficient material to give the pressure screws a good purchase. The lower cross strip should be notched in the manner illustrated.

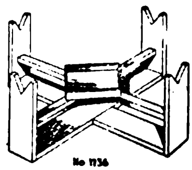

Fig. 3.

Fig. 3—Though designed for work on the Ford rear axle, this stand could readily be adapted to the requirements of many makes of axles. The ends of the axle are supported on notched uprights, about 30 in. from the floor and the torque tube is placed on either of two uprights similarly notched.

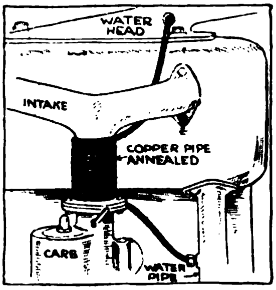

FIG. 2—HOT WATER JACKET FOR MANIFOLD

Fig. 2—Method of heating a long inlet pipe. Annealed soft copper pipe, small size is connected with discharge pipe from water pump, wrapped around manifold and connected with head.

Heating the Mixture on Old Carburetors.

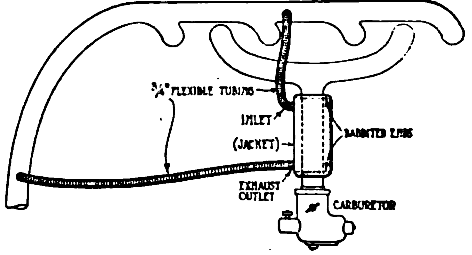

Fig. 10—Improving old type carburetors which were designed for gasoline of higher vaporizing qualities and long inlet pipes.

Many of the old model carburetors do not work well on the present low grade gasoline. If too ancient, it is best to get a new model, but where in good condition the older models can be improved by adding a hot air jacket as shown in fig. 10.

Use a pipe of some kind and slip over the intake manifold—about ¾ of its length. Weld gas tight at each end (sheet iron can be made into a pipe) and pour light layer of babbitt in each end to close up any holes or cracks.

A ⅜, ½ or ¾ inch (larger the better) flexible pipe is then attached to top and bottom of jacket to exhaust pipe as shown, or lower pipe can extend to lower part of engine—see page 157.

Fig. 11—Another method of heating the carburetor mixture on old cars that have a long inlet manifold. A ⅜ or ½ inch copper pipe is tapped to the exhaust manifold and run down along the intake manifold, being held away from the latter slightly by asbestos pads. Asbestos is then wrapped around the manifold and pipe and the heat thus obtained will help to prevent the gases from condensing in the manifold at the point where it branches out to the cylinders.

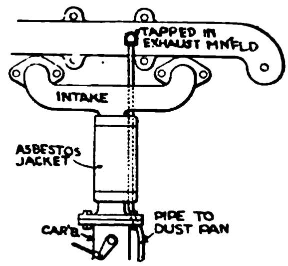

Fig. 11.

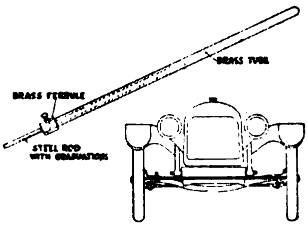

Fig. 4.

Fig. 4—The brace rod from an old windshield may be made into an excellent wheel alignment tram. After cutting the rod to a length about 2 in. less than the distance between the front wheels, a brass ferrule is soldered to one end. This ferrule is then drilled and tapped to carry a thumb screw in the manner shown. The adjustable part of the tram is a piece of ¼ in. drill rod, marked off into $1/16$ in. divisions as shown, and placed within the tube.

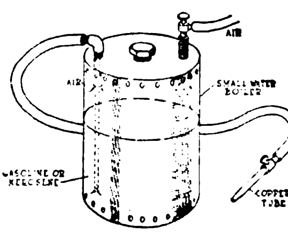

Fig. 5.

Fig. 5—This is a cleaning tank, in which gasoline or kerosene is forced by air pressure in a form of a spray onto the part to be cleaned. The container is an old hot water heater boiler. Air pressure is applied through a tire valve soldered to the tank, and the cleaning solution is drawn up through a small tube to the outlet pipe. A length of rubber hose, terminating in a copper tube, fitted with a valve, completes the outfit. Either gasoline or kerosene may be used as a cleaning solution, but the latter is preferable.

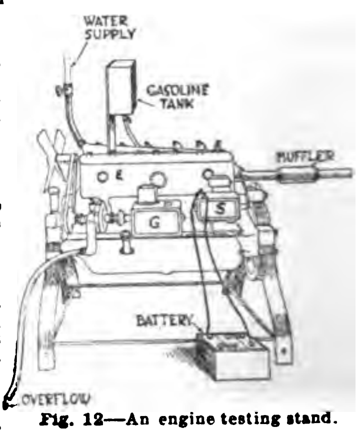

Fig. 12—An engine testing stand.

By supporting the engine on a cast-iron stand, and operating it from an auxiliary gasoline tank, storage battery, water supply, etc., the performance of the engine may be observed and the necessary adjustments made without difficulty.

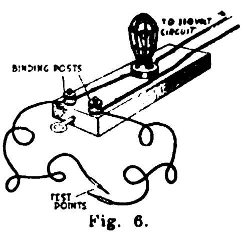

Fig. 6.

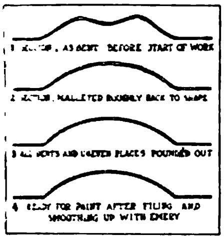
Fig. 6—This is a portable test lamp, used in conjunction with a 110-volt lighting circuit, for testing lighting and ignition circuits on the car. It consists of a wooden base, on which is mounted a porcelain socket carrying a 16-candle power lamp, connected to the lighting circuit as shown in the wiring diagram. The test points are connected to the binding post, and any metallic connection between the two causes the lamp to light. Hence if a wire is O. K., the lamp will light, when the test points are placed on each end of the wire. If there is an open circuit, it will not light. Similarly short circuits and grounds may be determined. By short circuiting the two binding posts, the lamp may be used for inspection work.

CHART NO. 308-A—Miscellaneous Shop Hints.

(Motor World.)

Metal Straightening.



The four steps in removing a dent from a sheet of metal

There is but one secret to sheet metal straightening; to support all parts except that which is to be straightened, and to go slow, working the metal back to its original form by light blows.

To do this requires many special tools, some of them taken directly from the tinsmith trade, others can be developed on the job.

The Tools.

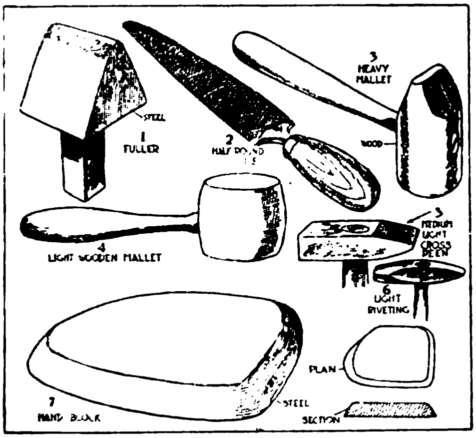
1—**The Blacksmith's fuller.**—This is used as a hand anvil, either in conjunction with the light mallet, or the light hammer, particularly to remove small dents. The combination of flat surfaces with the rounded edge will cover a wide variety of work.

2—**Half round file.**—After all dents or indentations have been removed by use of the mallets, hammers and hand anvils, this file is used to remove any small pits or hammer marks.

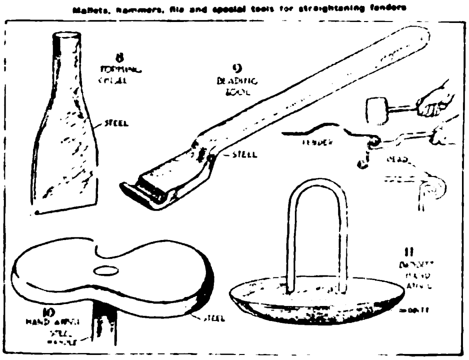
3—**Heavy wooden mallet.**—Used in the preliminary straightening to roughly form the metal back to shape. The flat wooden surface does not dent the metal on flat or crowned surfaces.

4—**Light wooden mallet.**—The most useful tool of all. After the metal has been pounded back to its original shape, the light mallet, in conjunction with some one of the hand anvils, is used to smooth up the work.

5—**Medium cross poen hammer.**—A tinsmith's hammer, used to still further smooth up the surface. Wooden mallets will not remove all of the smaller indentations. Hence this hammer must be used as it strikes the required concentrated blow over a limited area.



Mallets, hammers, file and special tools for straightening fenders



A few of the strangely shaped tools used in repairing fenders

6—**Light riveting hammer.**—Any minor indentation, not smoothed by No. 5 hammer, is taken out by the light riveting hammer. The cross poen is used to finish corners, prior to filing.

7—**Hand block.**—A steel block, roughly about 4 in. square, and 1 in. thick, with the corners rounded and beveled. The curves and beveled edges vary, so that some part of the block may be fitted to almost any part of the work. This and the light wooden mallet are the most used combination.

8—**Forming chisel**—Made in an infinite variety of widths, shapes and sizes. The one shown is used to form sharp corners, or edges. One with a half-round edge is used to re-shape a groove. By grinding the edge to the desired form, the metal may be readily driven to that form.

9—**Beading tool**—The side strips on most fenders are held in place by rolled-in edges. When bent, these edges open. After straightening to the original form, the bead may be again closed by the aid of this tool, and a mallet or hammer.

10—**Hand anvil.**—An irregular shaped steel plate or block, mounted on a steel handle. The edges are beveled, and will fit almost any curved surface.

11—**Babbitt hand anvil.**—Made in an infinite variety of forms by pouring melted babbitt into an unbent portion of the part to be straightened. When hard, the shape is that to which it is desired to form the bent portion. Make handle as shown.

Reshaping Bent Metal.

It is not usually advisable to attempt to straighten mudguards and lamps having broken surfaces.

The first step is to work it roughly back to its original shape with a heavy wooden mallet. Care must be taken not to break the surface or to draw it beyond the original shape.

A hand anvil of some sort should always be used in conjunction with the hammer or mallet to support the edges of the bent surface. Many light blows, rather than few heavy blows, should be applied, and the blows should be drawn, rather than applied dead on. The main thing is to go slow to feel the dents with the hand anvil, and to direct the straightening blow to the point of bend.

After the surface has been malleted to approximately the original shape, the smaller dents should be removed, using first the small mallet and then one of the metal hammers. This is slow work.

Filing.

By passing the hand over the surface, many of the smaller dents may be felt and removed. Some, however, will still remain. These may be located by filing the surface down. The file will hit the high spots and pass over the low spots. Then the low spots may be pounded up to shape.

Finally it will be found that the file will touch all of the surface except the smallest indentations. Then file the whole surface down to a smooth surface and polish with emery paper.

The four steps in this work are shown on this page, the section being that of a crowned mudguard. But mudguard, lamp or body, the principle is absolutely the same.

Painting.

Before applying the paint, the surface must be thoroughly cleaned with turpentine. This removes all grease that would otherwise prevent the paint from sticking. If the surface is that of a mudguard the under side should also be cleaned and painted to prevent rusting.

For hurry-up jobs a quick drying enamel or a black japan may be used to paint the repaired section, the latter, of course, being only suitable for use on black guards or parts The japan, mixed in turpentine, will dry in about 15 min., and after a few washes cannot be detected from the rest of the finish.

Straightening Bodies.

Upholstery must be removed or the body raised to get at both sides of the surface. Another difficulty is that two men are often required—one to hold the hand anvil and the other to use the mallet or hammer. The co-operation between the two must be perfect or the anvil will not be back of the hammer blow and the surface will be still further bent. Body work is more difficult.

CHART NO. 308-B—Straightening Sheet Metal Parts. Tools Required and Methods—(see page 731). With a small investment in tools, a little practice and care in their use, a new department may be developed that will show a profit, and also feed other departments. (Motor World.)

See index for "top-repairing."

Truck Chassis; Chain and Worm Drive.

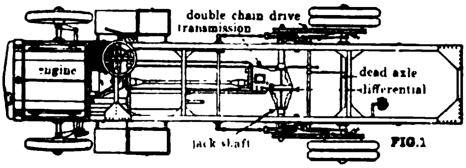


Fig. 1—Top or plan view of a truck chassis using a double chain drive. Note the rear axle is a "dead" type of axle and the differential is mounted on the jack-shaft—see pages 18 and 20. The engine is a four cylinder engine. In fact, most truck engines are four cylinder—see page 747.

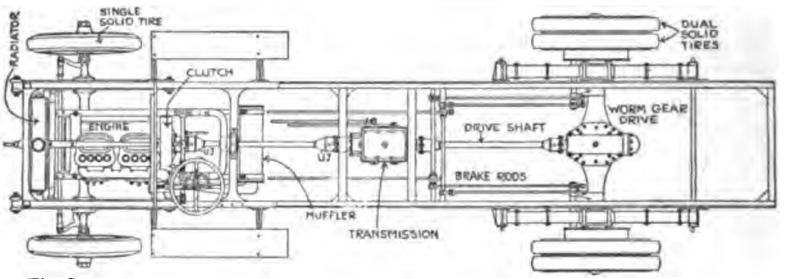

Fig. 2.

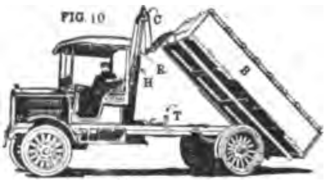
Fig. 2—Top or plan view of a truck chassis using a worm gear drive. Note the rear axle is a "live" type of rear axle. The differential is mounted on the axle shafts. See fig. 3, page 750 and pages 32, 35, 21.

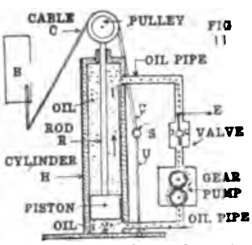
Dump Body and Hoist.

A dump body is used for hauling coal, sand, gravel, etc. The body is made to fit on a hinge at rear of chassis as shown in fig. 10. **A hydraulic hoist,** which derives its power from the engine raises the



front end of body. The operator can raise body and dump contents in about thirty seconds. Hoists which can be operated by hand are also in use.

Principle of operation of the hydraulic hoist is shown in fig. 11. It is essentially identical in principle of construction to that of a hydraulic elevator. **To raise body:** An oil pump (gear type) at the base of the cylinder (H) draws oil from the

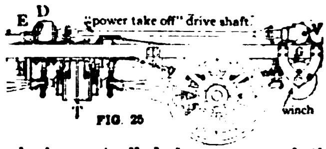


top of the cylinder at (1) and forces it into the lower part at (2), raising the piston which in turn raises the rod (R) to which is attached grooved pulleys, in which grooves the cables (C) are placed. One end of cable is attached to a stationary rod (U) and the other end to body. As the rod (R) is raised, the body is also raised. **To hold body at any desired angle:** The oil pump is shut off and valve closed. **To lower body:** The drive of oil pump is shut off and valve (by-pass valve) is opened by a lever (E). The weight of the body forces piston down, driving the oil back to upper part of cylinder. **The oil pump is driven** from gears in transmission by a special and separate arrangement whereby car is not driven when in operation. The cylinder is usually filled within ⅛" of top with ice machine oil.

Winch Equipment.

A winch, fig. 25, is a drum located under rear end of frame, supplied with 200 or more feet of ⅝" cable, for unloading and loading heavy material and for various other purposes.

The power for driving the winch (on the F. W. D. truck) is taken from gears in the transmission (T) through D, which is equipped with a separate clutch to a "power take off" drive shaft. To gears in housing (V) which connects to winch through a spur gear (G).



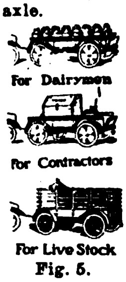
The winch is controlled by means of the clutch foot pedal, after clutch in D has been engaged. The winch may be operated while truck is either standing still or in motion, but not when transmission is on high speed. Di. winch drum 7¾", length 22¾", total gear reduction to winch, 33.2:1.

*Trailers.

Trailers are attached to rear of cars and are now extensively used. They are particularly desirable where goods of relatively light weight and great bulk have to be carried. The trailer can be adapted for many uses.

There are three general designs as follows: The **four-wheel trailer** (fig. 5) has a large possible field of utility and can be used in practically any service, for instance, freight and baggage, dairymen, contractors, live stock, pianos and furniture, plumbers and painters, farm products, camp outfits (see page 516).

The **two-wheel trailer** has the load balanced on its axle.



For Dairymen

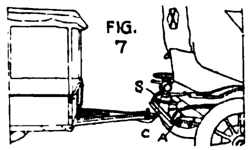
For Contractors

For Live Stock

Fig. 5.

The **semi-trailer** also uses two wheels but the load is not balanced over its axle, rather the front end of the load rests on the tractor vehicle.

Trailer attachments: Fig. 7 shows trailer attached to rear of a car by means of a piece of angle iron (A) which is attached to springs (S). This is not recommended as the strain is too great on the springs. **Fig. 6** shows two methods which are better. C is one type of coupling.



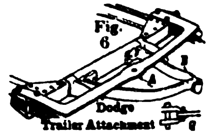


CHART NO. 309—Trucks; Chain and Worm Drive. **Trailers. Dump Body with Hydraulic Hoist.**

*See also, pages 822, 516.

INSTRUCTION No. 47.

COMMERCIAL CARS: Trucks; types and construction. Truck Chains, Worm Driven Rear Axles. Trailers.

**The Automobile Truck.

It is interesting to note that the automobile truck and delivery wagon manufacturers have increased at a very rapid rate, greater in proportion than the passenger car.

Probably the subject of trucks will interest many of our readers as it is fast taking the place of horse drawn vehicles. There isn't much to be treated in this subject, however, as the truck as a whole, is precisely the same principle as the pleasure car—with the exception of minor details of construction which will be taken up in their respective order.

Therefore for one to master the truck construction and operation, he has but to refer to the subjects of **engines, carburetion, ignition, lubrication, operating a car, etc.**

We will classify the commercial cars into two divisions; motor delivery and trucks.

The motor delivery is usually an automobile of the pasenger car class, with a special delivery body, as illustrated on page 16. Inasmuch as this type of car was treated in previous Instructions, it will not be further dealt with here.

The truck is constructed along the same lines, except the chassis is heavier and chain or worm drive is usually employed.

Trucks are made in sizes from ½ ton capacity to 10 tons and over. The greatest number in use being the 1 to 2 ton capacity.

How to select a car for commercial use is treated on page 528.

The motive power. Trucks are propelled by either gasoline engines or electric motors.

The electric type is dealt with on page 477. See also page 484.

Truck Engines.

The general principles of the engines are identically the same as used on pleasure cars; the ignition, carburetion, clutch and all parts, with minor exceptions as governor and starter, and the drive principle, is identically the same. Therefore, if the reader will master the above subject he will then understand the construction of a truck.

Four cylinder engines are used mostly on trucks. Some few manufacturers use the two-cylinder-opposed type engine, but not six, eight or twelve. See page 833 for a typical 4 cyl. truck engine.

The four cylinder engine is more efficient for truck and tractor use, than a six or twelve cylinder engine. The four has less parts, simpler to care for and as the speed is less than that of a pleasure car the four cylinder engine is the adopted type for trucks and tractors.

Ignition must be positive and simple and as the speed is limited, and due to the governor action on the carburetion mixture to cylinders, the magneto is the adopted type of ignition for most trucks—see pages 255, 277, 832, 312, 285.

Starting is usually by means of the "impulse" starter—see pages 832, 277, 255.

Governor. Most all high grade trucks use governors—see page 839. **Gasoline feed** is usually the gravity principle.

Truck Drive.

The drive method is usually one of two methods; the double chain or the propeller shaft. See page 746.

The double chain drive has the advantage of a solid or "dead" rear axle but has the disadvantage of a chain, which causes considerable wear and jerky action.

The worm driven rear axle is considered the best. A "live" axle is used, but constructed in such a manner that it is as substantial as a "dead" axle.

See page 748 for the "four-wheel drive" truck on page 678 for the "internal" gear driven axle.

Speed of average truck is 9 to 17 m.p.h.

Gear shift is usually the S. A. E. standard, page 490.

Gear ratio—Three speeds forward are usually provided, giving ratios in the gearbox of 4 to 1, 2 to 1 and 1 to 1; and with a rear axle ratio of 10⅓ to 1 the total reduction is 41⅓, 20⅔ and 10⅓ to 1. The face of the gears is on an average about 1½ inches wide.

***Details of Three Models.**

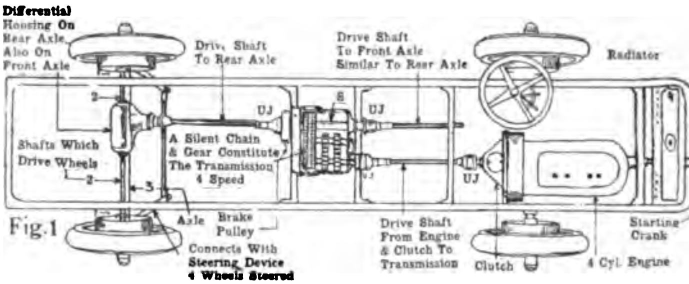
Capacity, lbs.	2,000	4,000	7,000
Price	$1,575	$2,200	$3,000
Wheelbase, in.	128	148	168
Tires, front	34x3	36x4	36x5
Tires, rear	34x4	36x6	40x5
Bore	3½	4⅛	4½
Stroke	5	5¼	5⅛
Horse power	19.61	27.20	32.40
Speed, r.p.m.	1,700	1,300	1,200
Speed, m.p.h.	22	17	14
Gear, ratio in high gear	7¾-1	8½-1	10¼-1
Final drive	Worm	Worm	Worm

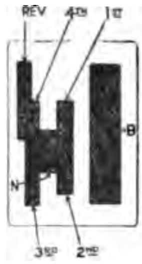
Operating a Truck.

It would be merely a repetition to go into details here as to operating a truck, because it is identically the same principle as explained in operating a pleasure car under instruction No. 34.

Trailers—see pages 746, 822.

*The prices are now considerably more. **See also, pages 822, 825, 821, 484.





Nash Quad Truck.

Drive method: All four wheels are driven by means of two drive shafts leading from the transmission (fig. 1). to a differential housing (fig. 2) mounted on "dead" rear and front axles.

In order that the front wheels can be turned for steering, universal joints (B, fig. 3) are connected to shaft flanges (F. fig. 2). There are internal gears in all wheels by which they are driven. All four wheels are steered, see fig. 3.

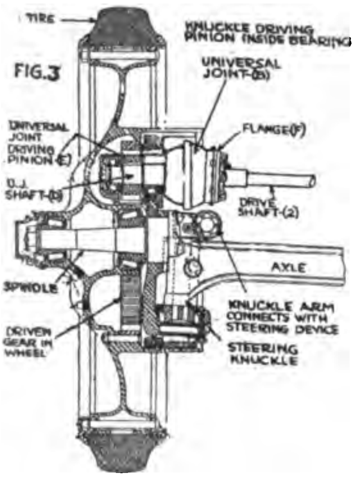


Fig. 3—One of the 4 wheels illustrating how the shaft (D) of universal joint (B), on which is a pinion (E) drives internal gear in wheel.

Steering is by connection in usual way of the knuckle arm with steering device.

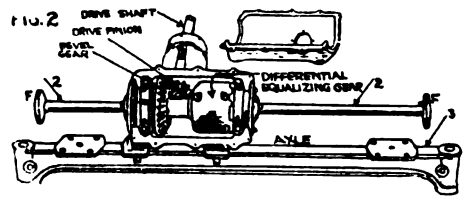

Fig. 2—Illustrates the method of placing the differential housing on the "dead" front and rear axle with drive shafts (2). which drive the universal joint (B, fig. 3) by flange connection (F).

Specifications of the Nash Quad.

Engine is (Budda) 4 cylinder; L type cylinder 4¼x5½. 28.9 h. p.; **Ignition** is type "G4" Eisemann magneto, page 285; **Carburetor**—the model "L" Stromberg, see index; **Governor** is the Simplex, see index, this governor cuts off at a speed of 14 miles per hour or engine speed of 1500 revolutions; **Clutch** is the Borg and Beck, page 42; **Brakes** are internal expanding in each wheel and one external contracting on drive shaft. **Tires** solid rubber 36x5; **Wheel base** 142 and 124 inches; **Tread** 56 inches; **Capacity** of truck is 4000 lbs., maximum is 5200 lbs; **Fuel tank** 26.7 gallons with reserve tank of 5 gallons; **Water capacity**, 11 gallons.

F. W. D. Truck.

Drive: Power from engine (fig. 20), is transmitted through a Hele-Shaw clutch (see fig. 4, page 40), to main transmission, thence through a silent chain to a sub-transmission, thence to front and rear "live" axle through drive shafts P. The front and rear axles are similar to other automobile "live" rear axles, except it is necessary to have universal joints connected with spindle of front wheels so that the front wheels can be turned for steering. The steering device connects with the front wheels, not the rear. (See fig. 60 and 61, page 690 for steering device used).

The locking center differential: A feature of this truck is a center "locking differential" in the sub-transmission. Normally this differential is in action to compensate for the difference in speed between the front and rear axles when turning corners. Thus, by the center differential action tire economy is assured. Should the truck be in a position where the rear or front wheels are slipping, the center differential can be locked by means of a lever (L), operating a clutch connecting with each drive shaft, so that the differential action is thrown out of use and all four wheels driven at the same speed. When truck has been extricated from the soft spot, the locking lever (L) is released and differential is again in action. If one of the axles is permanently damaged or disabled the propeller shaft (P) can be disengaged and other axle used. There are also differentials in the front and rear live axles.

Specifications of F. W. D. Truck.

Model B, 3 ton; Wisconsin T-head, 4 cylinder, bore 4¾"x5½" stroke with cylinders offset ¾" and rating of 36.1 h. p.; **Ignition,** Eisemann high tension magneto with impulse starter; **Carburetion,** Stromberg model G; **Governor,** Pierce (page 840), adjusted for maximum speed of 14 m. p. h. on high speed; **Tires,** 36x6; **Gasoline tank,** gravity feed, 30 gallons; **Gearshift,** same as fig. 1, page 490. **Load distribution,** designed so that 45% of total load is carried on front wheels and 55% on rear wheels. **Transmission gear ratio,** 1:1 on high, 2:1 on second, 4:1 on low and 4:13:1 on reverse. **Total gear reduction** 8.9:1 high, 17.80:1 on second, 35.60:1 on low, 36.07:1 on reverse.

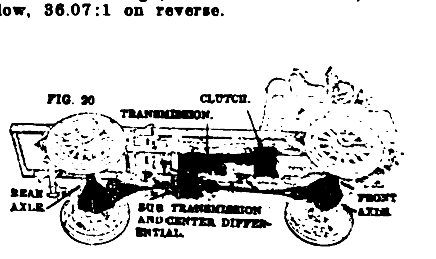

CHART NO. 309X—Explanation of Two Four Wheel Driven Trucks.

Nash Motor Co., Kenosha, Wiscn.; Four Wheel Drive Auto Co., Clintonville, Wiscn. Another well known make is the Duplex Truck Co., Lansing, Mich.

Truck Chains.

Baldwin roller chain "master link" with cotter pins and an extra roller link, for coupling.

Roller type chain: The truck chain is usually what is termed a roller type of chain. The roller part is clearly shown in the illustration. This is the part which fits in between the teeth of the sprocket.

1 ton truck; pitch 1";	di. roller 9/16 or 5/8";	width roller 5/8 to 3/4".
2 ton truck; pitch 1¼";	di. roller 5/8 or 3/4";	width roller 1/2 to 3/4".
8 ton truck; pitch 1⅝";	di roller 1";	width roller 3/4 to 1".
5 ton truck; pitch 2";	di. roller 1⅛";	width roller 7/8 to 1¼".

The pitch is measured from center to center of link, when roller type. The **width of roller** is measured along its length and the **diameter** is measured cross-wise, (or refers to its thickness).

To remove a chain the master link cotter pin or sometimes a wire clip is removed and the master link withdrawn.

On some chains the parts are detachable and the. chain can be lengthened or shortened with ease, whereas with the solid chain the task is not so easy—a special tool must be used.

Care of Chains.

If chains could be protected from dust and be run in an oil bath, they would last much longer, but no method of doing this has yet been successfully devised. A case or housing cannot be fitted around the chain, because the construction would also require it to contain the brakes as well as the sprocket, and to surround the axle.

When chain becomes too slack the chain and sprocket are bound to suffer in consequence.

When chain is worn an uneven or jerking motion is imparted to the drive system when slowing down, coasting and suddenly picking up speed etc. Therefore a chain should be well lubricated and kept adjusted.

Cleaning and Lubricating.

Tallow gives a chain the best protection against dust and grit. It is melted and chain (after being cleaned by soaking in kerosene) is laid in the liquid tallow—hang it up to dry and then wipe off the surplus grease—see also, page 741.

Teeth of sprockets when worn may be remedied in some instances by reversing.

A new chain will stretch—a link should be removed after it is well set. The rivets are cut with a chisel. Master links should be carried.

Adjusting chain tension—slight play is necessary, but equal slack should be in each chain. They should be loose enough to run easy without climbing the sprocket tooth. Adjustment is usually made by the radius rod, or large adjusting screws provided for the purpose. (see page 20 showing radius rods equipped with right and left adjusting device).

The enlarged section in middle portion of radius rod is an enlongated nut, which is tapped with both right and left hand threads. The rods have threads cut on them to correspond. Turning the nut in one direction lengthens the rod and turning it in the opposite direction, shortens it. The principle is identically the same as in a turn buckle, this however is a much stronger construction.

Truck Tires. Rear Axle and Spring Lubrication.

Tires—several forms and types of solid tires used for truck service are shown in the tire instruction, see pages 555, 560 and 561. See page 741, how to remove a truck wheel.

Truck Rear Axles.

There is very little to be said about the chain driven rear axle as the wheels revolve on the spindle of the dead axle—usually on roller bearings. See page 31 for illustration of a dead axle and page 20 for a jack shaft—also page 746.

The worm driven rear axle is the popular type in use and as an example the Sheldon is explained on pages 750, 751, and the Timken, page 762.

Springs.

Springs—inasmuch as the springs of a truck are subjected to considerable strain, they should be kept in good condition. A method usually employed is to raise the frame of car with a jack as shown in fig. 12, which causes the leaves of spring to separate—graphite is then inserted between the leaves and wiped dry after removing the jacks. The spring clip nuts should be tight.

A Truck Gear Box Alignment.

When replacing the gearbox on trucks having separate jackshaft brackets (as in the chain drive Mack), it is advisable to test the jackshaft and gearbox alignment (fig. 13). To do this, cut two disks of 1-64 in. galvanized iron to fit the outer bores of jackshaft brackets, and drill a small hole through the center of each. These disks are placed in the outer bores of each bracket, and a fine thread passed through the drilled holes and the gearbox in the manner illustrated. Measurements from the outside of the bearings to the thread show when the alignment is perfect.

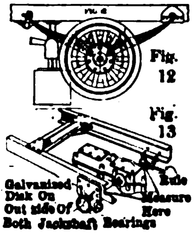

Fig. 12

Fig. 13

The Powrlok or M and S Differential.

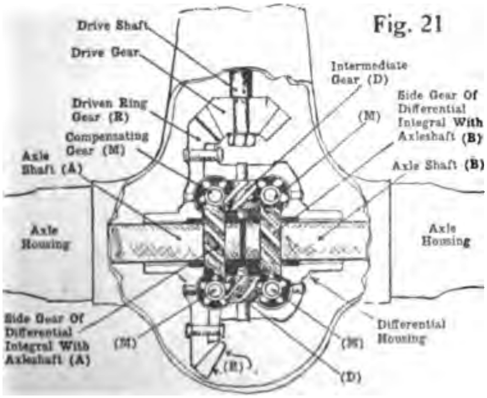

Fig. 21

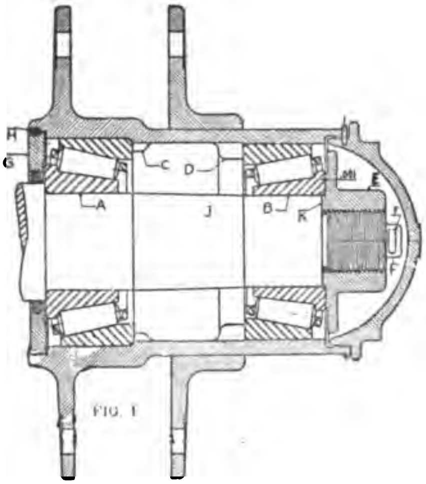
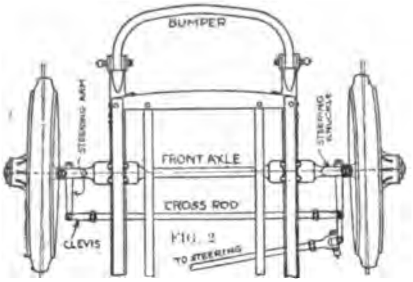
With an ordinary differential as shown on page 34, when one rear wheel gets into a soft spot it will turn or spin. With this differential, nothing of the kind happens because the angle of the worms (D and M) is such that, while the side gears on axle shafts (A and B) can drive the worms, the **worms cannot drive the gears on axle shafts** (A and B), and as a consequence the differential is locked, or axle is like a solid axle so far as the movement of the wheel in relation to the differential is concerned.

When both wheels are firm on the ground and can travel freely, the differential is enabled to act in the usual manner when turning corners, etc., by reason of the fact that the **gears on axle shaft (A and B) can drive the worms.**

This device prevents skidding to a great extent and insures positive traction at all times. (Mnfgr's Powrlok Co., Cleveland, O.)





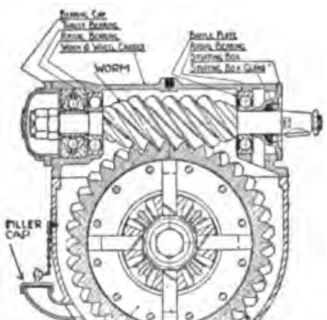


FIG. 3 AXLE HOUSING

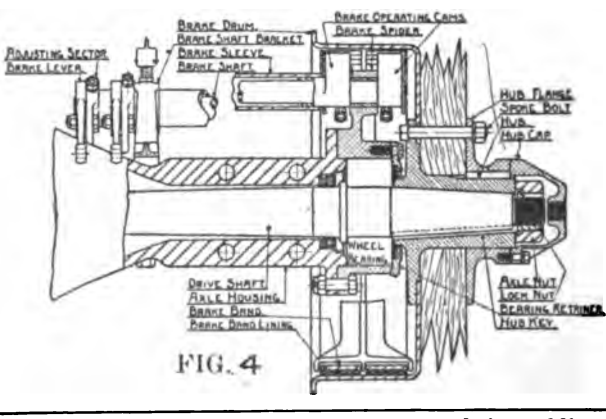

FIG. 4

Front Wheels.

Fig. 1—To mount front wheel bearings—taper roller: (1) insert bearing (A) in the hub and press against shoulder (C). (2) screw retainer (G) in place and lock with screw (H). (3) insert bearing (B) and press against shoulder (D). (4) mount hub on spindle (J) and tighten nut (E) against shoulder of axle (K). (5) there should not be more than 1-1000 inch clearance between nut (E) and bearing (B). To secure this fit, the hub should not be able to slide back and forth. There should be no endwise movement of spindle, but the bearings should not be bound and the hub should move freely. Shoulder on nut (E), could be filed down if hub does not fit freely. If wheel revolves freely you know adjustment is o. k. If not try another nut, having shoulder (K) more full.

Care must be taken that inner bearing seat is tight against the collar on the spindle. Test by moving wheel from side to side.

Fig. 2—Wheel alignment—To test; jack both front wheels up—with chalk held in fixed position against tires, spin wheels, drawing line around the tire. The distance between the lines measured at the front of the wheel should be from ⅜ to ½ inch less than in the rear.

To "**take in**" or "**let out**" on **wheel alignment**—Loosen clevis jam nuts on end of cross rod. Remove pins—screw clevis either in or out as needed. If steering knuckle is bent or steering arm is bent, replace it. If cross rod is bent—straighten before re-aligning wheels. Front wheels are "cambered" so wheels are little closer together at the bottom than at the top. See page 683 for "camber" and "toe-in."

Rear Axle.

Is of semi-floating type (see page 33.) Axle is mounted throughout on ball bearings except that straight roller bearings on the wheels are sometimes provided. Lubrication of the worm gears is very important. To put oil into housing—(see figs. 3 and 5)—unscrew filler cap and pour oil in until it overflows. When new it may be necessary to add oil every two or three weeks, if oil level goes down. Drain old oil every 5,000 miles and flush out with gasoline and thoroughly clean. Heavy oil such as 600W (steam cylinder oil) is best for worm gear lubrication.

Removing Rear Wheels.

To remove rear wheels, a wheel puller (fig. 6, chart 309-B) is provided. Jack up axle, unscrew cap screw (A), remove hub cap (B), remove drive shaft nut (C), press out disc (D), replace hub cap (B), insert set screw (E), and jam against drive shaft (F), tap back of wheel (G).

Do not attempt to pull wheel off by simply tightening up on the set screw. Be sure to tap against rim of wheel on inside, after you jam the set screw against the shaft, otherwise you are liable to strip the threads.

Replacing Rear Wheel.

In replacing wheel on shaft, put key in position in key way, then place hub over shaft with key way in hub in line with key on axle shaft. You may not be able to get nut (which jams key) screwed in far enough at first, because the hub will not be far enough up on shaft. Do not attempt to draw the hub up with key jam nut alone, but drive wheel on and take up with the nut as hub creeps on the shaft. When hub is well up in position, take off outer nut, jam the key tight against the bearing with jam nut and then place outer nut back in position before putting on hub cap.

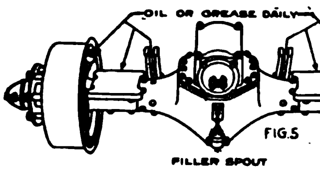
Removing Worm and Wheel Carrier.

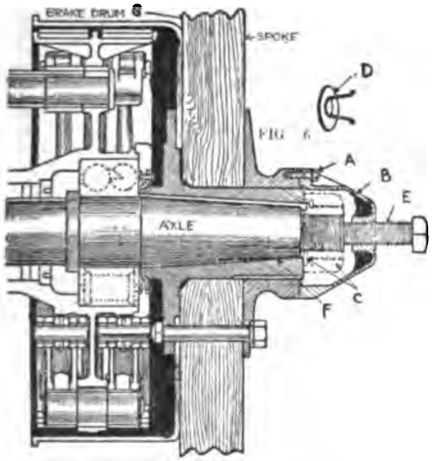
They come out as a unit complete with worm gear, differential, etc. (fig. 7, chart 309B.) Before lifting out carrier, the axle shaft must first be removed and the carrier unbolted from the axle housing.

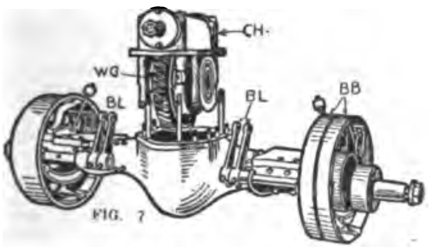
Procedure: Jack up wheels and remove; take off wheel bearing retainers by unbolting them from brake spiders, (fig. 8); pull out axle shafts, remove

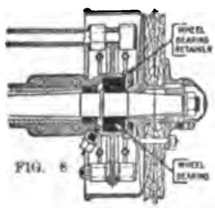
HART NO. 309-A—Adjusting, Removing and Assembling a Truck Rear Axle. (Sheldon worm drive type as an example.)

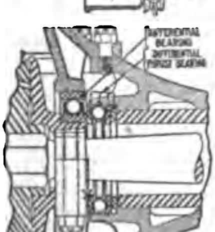
ee page 762 for Timken Worm Drive Truck Axles.











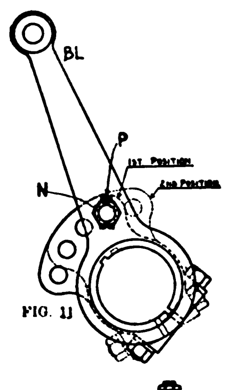


Fig. 9.—Top view of carrier and housing. Bump housing on top at points marked by black squares to loosen carrier from housing.

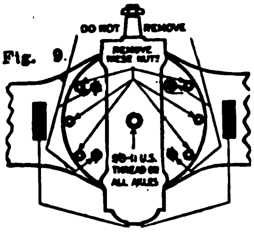


nuts which fasten carrier to axle housing marked "remove" (fig. 9.) These nuts are all near the outside edge. Do not disturb any of the other nuts, as they have nothing to do with carrier removal. Fit an eye bolt (any blacksmith can make) into the hole in top of carrier (fig. 9) and lift out carrier with chain hoist by means of this bolt. If entire axle lifts up with carrier, bump housing lightly on each side of carrier with heavy bar at points marked by black squares (fig. 9), applying force downward. Do not use small hammer or hit too hard.

Do not destroy gasket by driving chisel between carrier and housing.

On W-30 and W-50 axles, used on 3 and 5 ton trucks, there is a thrust bearing on each side of the differential as shown in fig. 10. Be careful they do not fall into housing when carrier is lifted out. They can be held in place by reaching hand in axle tubes and smearing with heavy grease, while carrier is being lifted out. It is important that right hand bearing is re-assembled on right hand side and left hand bearing on left hand side Do not interchange.

Reassembling.

Reassembling: Remove drain plug and wash out carrier and housing with gasoline and clean thoroughly. See that all parts are clean. See that gasket between carrier and housing is in perfect condition. Set carrier back in place. On W-30 and W-50 axles put thrust bearings on same side from which removed. On these axles they must be put in place before carrier is dropped in, and must be held until carrier gets down far enough to keep them in their proper position. This can be done by smearing with heavy grease as before mentioned. Bend a short hook of ¼ inch iron, insert the hand holding the hook in axle tube and hook over bearings at bottom, at point X, fig. 10, applying sufficient pressure, pulling towards you to keep bearings from falling out.

Bolt carrier in place. Put axle shafts in place, making sure that the hex part of shaft is shoved well back in hex part of differential case.

Replace wheel bearings, first washing them with gasoline. Pack bearings and also brake spider, with grease. The grease will then work into and through bearings when shoved back in place. Put on wheel bearing retainers and draw up tight. Replace wheels, being sure key that fastens hub to axle shaft is driven up well. Refill housing with oil. Run axle by hand by twisting on the front end of worm shaft to make sure it is in good condition before attaching the universal joint.

Brakes.

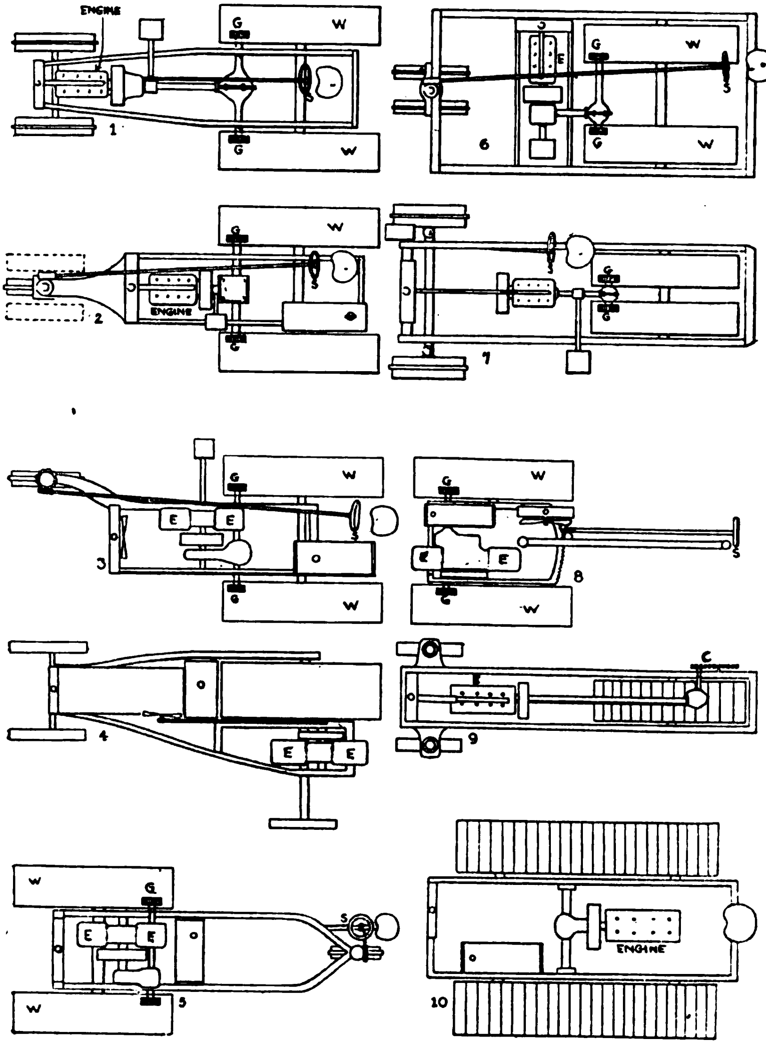
The foot brake is the regular service brake The hand brake is the emergency and for use when it is desired to set brakes while car is standing still. Both brakes on Sheldon axles are internal type, on the small axles they are of the cam type and on the larger sizes the "wrap-up" type. In this latter type the brake action gradually increases automatically.

Adjustment: Equal adjustment is essential. There is no adjustment in the brakes themselves (it being all in the parts which pull the brake levers.) On the late type axles the adjustment is made by a sector attached to the brake pull lever, as shown in fig. 11. To tighten up on the brake levers, simply take out bolt which fastens the sector to the lever, and move the hole in the lever one hole (towards the rear) on the sector.

On older type axles the adjustments were made by simply tightening up the pull rods.

In braking the truck with the engine with switch off and on low gear, care must be taken. If you intend using engine and low gear on a hill, engage your low speed before you reach the incline, because changing gears while a truck is rapidly descending is apt to strip the gears. The engine used this way makes a powerful brake and saves the brakes. The spark should be given just before reaching bottom of incline in order to start engine before actual bottom is reached.

CHART NO. 309-B—Sheldon Truck Axle—continuation of chart 309-A.



***Tractor Designs.**

1—Four-wheel tractor design with two large driving wheels in rear and two smaller steering wheels in front. The front wheels vary in diameter and also in tread. They are generally placed farther apart than shown.

2—Four-wheel tractor design in which two front wheels are so close together as to really serve as a single wheel.

3—Three-wheel tractor design with two large driving wheels and one steering wheel located at one side and in front. The diagram shows a two-cylinder engine.

4—Three-wheel tractor design with a double steering wheel and one very large rear wheel for driving. There is a second rear wheel made quite small for balancing.

5—Three-wheel tractor design using two large driving wheels and one very small wheel in rear for steering.

6—Four-wheel tractor design with large driving wheels in rear and relatively small front wheels for steering. Note the cross method of engine mounting.

7—Unusual tractor design, with two large steering wheels mounted very far apart and with two driving wheels placed very close together at the rear.

8—Two-wheel tractor design to which you can couple any piece of farm machinery. The entire power plant is mounted between the two driving wheels.

9—The combination wheel and caterpillar tractor, with a single caterpillar for driving in the rear and two steering wheels in front.

10—The short caterpillar using a caterpillar, or flat wheel construction at each side. This design has been on the market for some time.

E—is the engine; G—gears driving internal gears in rim of tractor wheels; W—tractor drive wheels. S—steering.

What a Tractor Must Do.

1st—Must work efficiently after six years.
2nd—Must reduce horses to the minimum.
3rd—Must supplant horses.
4th—Must cultivate row crops.
5th—Must plow and cultivate, both.
6th—Must handle two plows under bad conditions and three under good conditions.
7th—Must operate 7- or 8-ft. binder at 2½ to 3 m. p. h.
8th—Must have power to operate road grader, manure spreader etc.
9th—Must have belt power to operate any hay-baler or 24- to 28-in. threshing separator with self-feeder and wind stacker; must operate corn sheller, feed grinder, sawmill, etc.
10th—Must cost less than $1,000.
11th—Must weigh less than 5000 lbs. and be guaranteed one year.
12th—All working parts in oil; self-steering; direct drive for all speeds and belt pulley; speed enough for plowing and road work; low center of gravity.

Class of Work.	LIGHT WORK.	HEAVY WORK.
BELT WORK	Pumping, Washing, Cream Separating, etc.	Feed Grinding, Ensilage Cutting, Shelling, Shredding. Threshing, etc.
HAULING	Hauling People, Farm Produce, Merchandise, etc.	Hauling Grain, Building Material, etc.
FIELD WORK	Planting, Cultivating, Mowing, Raking, etc.	Plowing, Discing, Harrowing, Drilling, Harvesting, etc.

HART NO. 310—Tractor Designs. Diagrams Showing the Different Principles Used.
Motor Age.)
See page 829 for tractor drive methods.

*THE TRACTOR: Class of Work. Medium Size Tractor for General Farm Work. Gasoline-Kerosene Carburetors.

Fuel: The tractor was formerly propelled by a steam engine, but is now usually propelled by a gasoline engine, which uses gasoline or kerosene for fuel. *Two methods of using either gasoline or kerosene is explained in chart 311.

The engine can be either a multiple cylinder, vertical or horizontal opposed type. The 4 **cylinder engine** is used quite extensively and for the same reason as it is used on trucks, per page 747. The engine varies but in a few details from that used on automobile passenger cars. See page 832 for a typical 4 cyl. tractor engine—see also page 831.

The engine ignition is generally by means of magneto and with an "**impulse**" **starter**—see pages 832, 255, 277, 275, 747. The **governor** is used, as the tractor engine does not vary in speed so much as an automobile—see pages 839 and 832.

The drive systems differ however, but the same underlying principles such as clutches, jack shafts with differentials, etc. are employed, but of much heavier and larger design**—see pages 829, 830.

We would advise the reader to send for catalogues of some of the leading tractor manufacturers. These catalogues will give the reader the information on the drive methods and the instructions in this book on engines, ignition, etc. will give sufficient information on the engine. In this way one can gain a good working knowledge of tractors. The two gasoline-kerosene carburetion principles are explained on pages 754, 827 and the air washer on page 828.

A leading concern who has agreed to send descriptive catalogues, pertaining to tractors, to our readers, is the Minneapolis Steel and Machinery Co., Minneapolis, Minn. manufacturers of the famous "Twin City" tractors—see page 832. Other tractor manufacturers are Holt Mfg. Co., Peoria, Ill.; C. L. Best Tractor Co., San Leandro, Calif.; Yuba Mfg. Co., 433 Calif. St., San Francisco, Calif.

The address of three leading gas engine magazines are: The Gas Engine, Cincinnati, Ohio.; Gas Review, Madison, Wiscn. Gas Power, St. Joseph, Mich.

What a Medium Size Tractor Will Do.

The medium-size, medium-priced tractor, operating under average conditions will plow one acre 7 in. deep on 2½ gal. of gasoline and ⅛ gal. of lubricating oil. This, in brief, is the result of an extensive inquiry made by the United States Department of Agriculture embracing data received from 200 tractor users in the corn belt in Illinois.

The information is given in bulletin (No. 719) of the department, which is entitled "An Economic Study of the Farm Tractor in the Corn Belt," and which includes information from the users of tractors of various sizes and on various sized farms.

Best Size Tractor to Purchase.

Belt work represents 50 per cent of the total work of a tractor. For belt work to be thoroughly efficient the engine needs about the **same power** as is required for four **plows**, making the three and four plow outfits the best sizes for general utility on the farm.

Another important conclusion drawn from the data collected indicates the size of tractor most suitable for a given size farm and lays particular emphasis on the fact that the medium-size, medium-priced tractor "appears to have proven a profitable investment in a higher percentage of cases than any others." The sizes recommended for various sizes of farms are:

Acreage of Farm	No. Plows Handled
200 or less	3-plow
201-450	4-plow 3-plow second choice
451-750	4-plow 5- and 8-plow second choice

It is further noted that the smallest farm upon which the smallest tractor in common use—the 2-plow machine—may be expected to prove profitable, is one of 140 acres.

The bulletin further states, that the chief advantages of the tractor for farm work, according to the operators, are (1) its ability to do heavy work rapidly, thus covering the required average in the season; (2) the saving of man labor, and (3) the ability to plow to a good depth, particularly in hot weather. The chief disadvantages are put down as difficulty of efficient operation and packing of the soil when wet.

One significant fact brought out is that the purchase of a tractor seldom lowers the actual cost of conducting the farm and that the purchase of the tractor usually must be justified by increased yield.

With regard to the number of days a tractor is used, the report gives figures which vary from 49 for the 2-plow machine to 70 for the 6-plow machine. Nearly 45 per cent of the tractor users report that they do custom work for others, which would seem to indicate that the tractor is too large to be kept busy on the home farm. The life of tractors, as estimated by their owners, varies from 6 seasons for the 2-plow machine to 10½ seasons for the 6-plow outfits.

Repairs Cost 4% of Purchase Price.

The longevity of the tractor brings up the question of repair expense, and in this connection the bulletin points out that though no accurate statistics are available on this, it would seem fair to count upon probably less than 4 per cent of the initial cost annually. This represents the average for farm machinery generally.

Under favorable conditions a 14-in. plow drawn by a tractor covers about 3 acres in an ordinary working day. Under unfavorable conditions large gang plows will cover less ground per day per plow than will the small ones. Plows drawn by tractors do better work on the whole than do plows drawn by horses, the average depth in Illinois with tractors being 1½ in. greater than with horses. It is stated that the tractor displaces about one-fourth of the horses used on the average farm.

Power Required Depends Upon The Soil.

The resistance that soil offers to the passage of a plow bottom varies from 2 to 20 lbs. per square inch, depending upon the character of the soil.

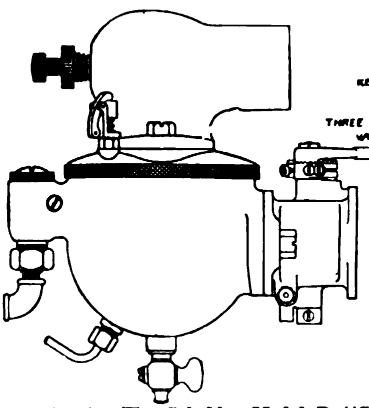
This being so, a bottom which requires a pull of only about 400 lbs. at the draw bar to turn a furrow 14 in. wide and 6 in. deep, may require as great a pull as 850 lbs. in a soil of different constitution, or a maximum of nearly 1700 lbs. in the most intractable soil.

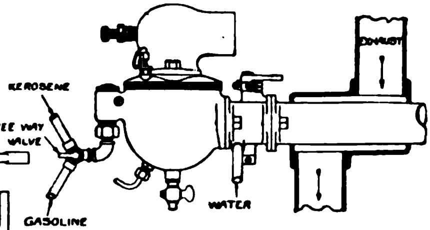
Therefore the **power of the tractor** must be determined by the **character of the soil and the number of plows it pulls.** One should secure a soil map of his locality from his State Agricultural College and post himself on the relative condition of the soil in his neighborhood and the power required before purchasing a tractor.

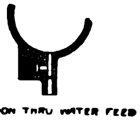
*See also page 829 for "Tractors;" 826 Ford Tractor; 827 Holley Kerosene Carburetor for Tractors. See page 831 for kerosene difficulties.

**The tractor engine must stand continued running at, (at least) three-quarter power for an aggregate of several hours steady running, therefore the bearings and parts of engine should be heavier and capable of withstanding this strain—see page 839 for "tractor drive methods" and 831 for "Transmission of power" and page 832 for a "typical tractor engine."

**Schebler Kerosene Carburetor—Single Type.







Schebler Model D (single) carburetor: The successful use of kerosene is not a problem of the carburetor alone, but involves both the carburetor and a proper design of engine.

It is absolutely necessary and must be understood, that kerosene can only be burned with the application of the proper amount of heat.

It is also advisable on some sizes of engines to heat the **incoming air to the carburetor,** and we find that it rarely occurs that too much heat can be applied to the air supply.

Fig. 1. The Schebler Model D "Single" Carburetor, with special water throttle for use with kerosene on tractor and stationary engines.

The intake manifold must be kept as hot as possible, perferably by the exhaust heat, for if heat is not applied, there will be a precipitation on the walls of the manifold.

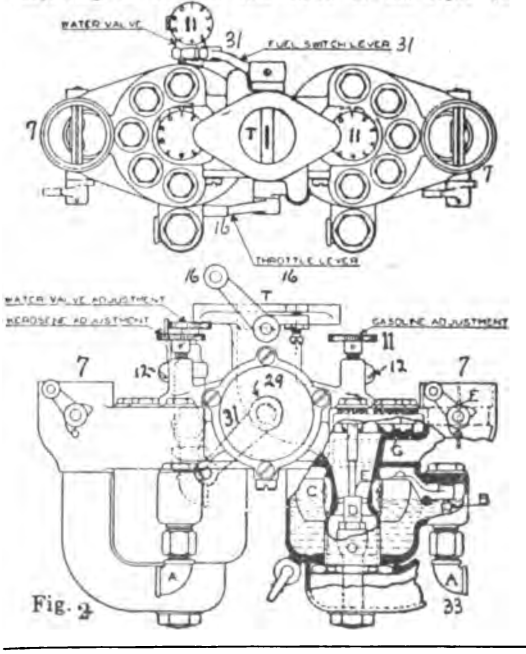
Heat on the manifold has two objects: First, to aid evaporation of the heavier parts of the fuel; second, to neutralize the *refrigeration produced by the evaporation, so that the incoming charge of gas introduced into the engine, is in an intimate mixture and at a uniform temperature.

Users of kerosene have always found it advisable to use water to prevent pounding under heavy loads; and also, water injection prevents excessive deposits of carbon. In this water or kerosene throttle attachment, there is a small hole in the carburetor side of the throttle, through which may be introduced a stream of water controlled by any suitable type of needle valve. While the engine is pulling a load, this needle valve which controls the supply of water from any suitable source, should be opened only sufficiently to remove the pound. When engine is stopped, water must be shut off. The engine must be started and warmed up on gasoline and then can be switched over to kerosene.

**Kingston Kerosene Carburetor—Double Type.

Kingston double carburetor: (shown in fig. 2.) This carburetor is so constructed that either gasoline, motor spirits, kerosene or distillate may be used by shifting of lever No. 31, which operates fuel switch valve No. 29 from one side to the other. The construction of carburetor with two bowls allows gasoline fuel to be supplied to one bowl and kerosene, motor spirits or distillate to the other, so after starting engine on gasoline and after it is warmed up, a switch to the other fuels can be made instantaneously by the shifting of lever No. 31. Then if engine refuses to pick up load, a switch back to gasoline can be made at once.

Adjustment: The fuel supply to each bowl is controlled by needle valves No. 11. The method of adjusting is to turn this valve to the right (first loosen lock screw No. 12) until it is down on valve seat. Then turn back to left one complete turn for preliminary starting. To adjust needle valves correctly, engine must be running up to speed, set spark lever in retarded position and follow out these operations: First turn the needle valve slowly to the right until the engine starts to backfire through carburetor. Then slowly turn to the left until the engine picks up maximum speed. Also notice the exhaust coming from outlet. After engine warms up and proper adjustment has been made, the exhaust should show up clear, no smoke to speak of. Too much fuel produces black smoke.



When engine is operating right, tighten lock screws No. 12. The needle valve lock spring is intended to hold adjustment of needle valve, but to make doubly sure that needle valve is held in proper adjustment the lock screw No. 12 should be set up tight. The needle valve is the only adjustment on the Kingston carburetor.

The auxiliary air is controlled automatically by ball valves see page 152, which takes care of the mixture at all speeds above or below normal speed so that after the adjustment is once made on the needle valves no further adjustments are required.

Stop valve at each of supply tanks should be shut off when tractor isn't being operated. The float valve in carburetor might stick or fail to keep supply of fuel to bowl or float chamber cut off, and it would mean that the carburetor would flood and fuel would run out and be wasted.

For tractor use—fuel must be connected to both bowls from both tanks when operating tractor.

Air washer: The Kingston carburetor (Kekomo, Ind.), uses an air washer, called the Bennett type, manufactured by Wilcox-Bennett Co., Minneapolis, Minn. See page 828 for principle and purpose.

CHART NO. 311—Carburetors for the Use of Kerosene or Gasoline.

*Cause; as the fuel is drawn through inner pipe, heat is required to evaporate it, consequently heat is drawn from pipe, leaving it cold, evaporation then stops—for this reason extra heating is supplied. (see also pages 155 and 158.) **See page 827 Holley kerosene carburetor and page 831.

Note; it is practically impossible to start an electrically ignited engine with kerosene when engine is cold. Kerosene does not give off vapor until heated nearly to the boiling point of water—it must be heated and kept heated, otherwise it will condense.

INSTRUCTION No. 49.

OTHER TYPES OF ENGINES: Motorcycle, Marine, Stationary Engines. Two Cycle Engine. Diesel Engine. Motor Bob. Re-designing Old Cars. Service Cars. Steam Cars.

Other types of engines are motorcycles, marine, stationary, Diesel, two-cycle, aero, etc. We will not attempt to give detailed explanations in this book—as it would require too much space to properly treat the subject; but to those who are interested in the above subjects we would refer them to Dyke's Motor Manual.

*Motorcycle Engine.

The motorcycle engine is usually a four cycle type of engine and is made with one, two and four cylinders. The air cooled cylinder is in general use. The "twin type" cylinder is the most popular and cylinders are usually placed 42 to 45 degrees apart. Why they are placed 45 degrees apart and such subjects as firing orders, etc. is fully explained in Dyke's Motor Manual, together with complete details of valve timing, driving systems, clutches, transmissions, etc.

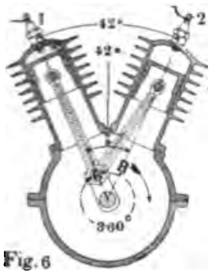


Fig. 6

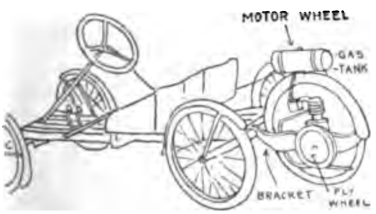
A twin cylinder motorcycle engine.

The connecting rods are usually placed on one crank pin, sometimes there are two crank pins—in the latter case the firing impulse would differ. The fly wheels are usually enclosed in the crank case. (see fig. 7, page 74, and Insert No. 3.)

The four cylinder motorcycle engine is also in use and is very similar to the automobile engine, but smaller and lighter.



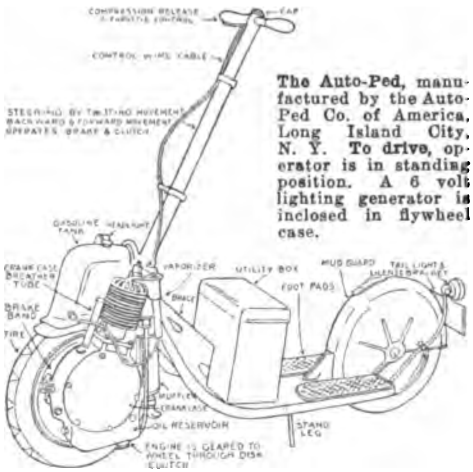
A "Motor-Wheel."

The Smith Flyer is a light motor vehicle made from a four-wheeled buckboard with a Smith "motor wheel" attached to the rear.

This machine though its entire weight is but 135 lbs., is capable of running at 20 to 25 m. p. h. and runs from 50 to 60 miles on 1 gal. of gasoline.

The control consists of a small thumb lever attached to the steering wheel and clutch and foot brakes are the same as those on a regular automobile. The wire wheels are fitted with double tube clincher tires and are 20 in. in diameter. The wheelbase is 70 in. and the tread is 30. The motor wheel is lifted about an inch off the ground by means of the clutch and is cranked by a handle on the drive wheel. By letting out the clutch the wheel is dropped to the ground. Price of this outfit is $135.00.

In winter the wheels can be removed and sled runners attached, making it a motor sled.



The Auto-Ped, manufactured by the Auto-Ped Co. of America, Long Island City, N. Y. To drive, operator is in standing position. A 6 volt lighting generator is inclosed in flywheel case.

Marine Engines.

Marine engines are also built along the same lines as the automobile engine when of the four cycle type, but with the addition of a governor on large engines.

The smaller types of marine or motor boat gasoline engines are frequently of the two cycle type. The two cycle type of engine is explained on page 756.

The marine engine is built heavier than the automobile engine because it is run most at full speed or power for long periods of time, however, on the modern marine engine it is capable of varying speed by use of the throttle and spark the same as the automobile engine.

The ignition for marine engines is similar to the automobile engine, but in many instances the "make and break" system page 260, and oscillating type, page 264, also K. W. is used. On the small two cycle type the jump spark with vibrator coil and battery is used to a great extent, also the make and break system described on pages 214 to 216. In fact, the make and break system is used quite extensively on large four cycle type of marine engine because it is of the low tension type and is not affected by dampness, which is the case where high tension current is employed. If high tension is used, then it must be well insulated because of dampness.

The carburetion is similar, but on some of the larger types of marine engines a double carburetor, using gasoline to start on and kerosene to run on is quite often used (page 754).

The clutch is used between the engine and reverse gear, and is practically the same principle as an automobile clutch.

A gearbox is some times employed which gives one speed ahead with a lower ratio than the direct drive. The reverse gear is also employed. Sometimes, however, the propeller itself is made so the blades will shift at various angles or pitch, (which

*See also pages 843 to 846, and Insert No. 3.

—continued on page 757

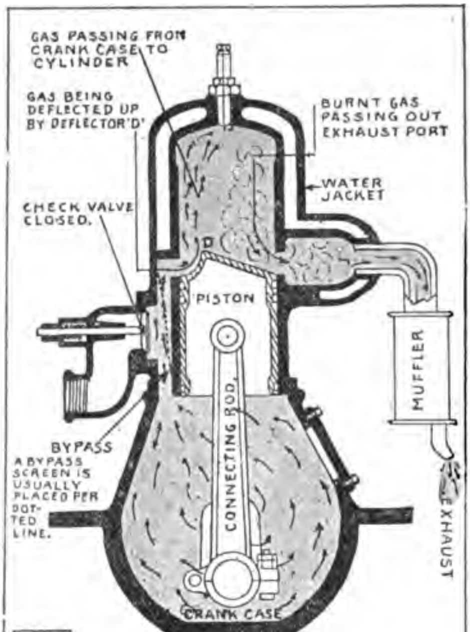


FIG.1.

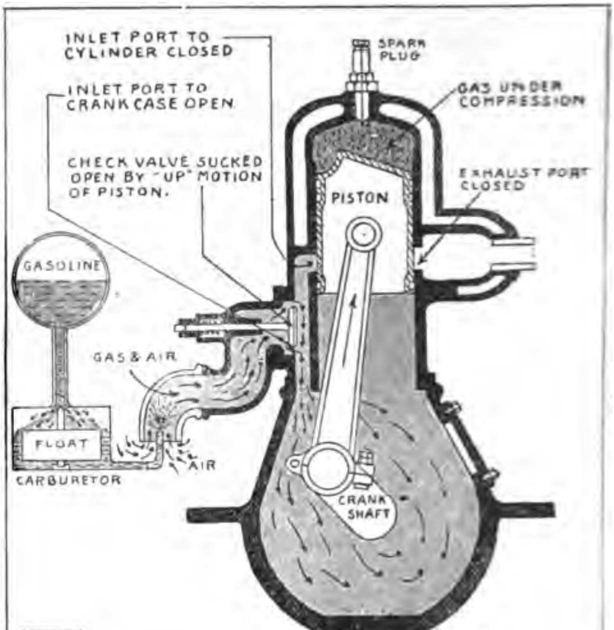

FIG 2

Two port two-cycle engine.—Fig. 1. Piston is now at bottom of its stroke. Notice two things are occurring; (1) gas entering cylinder from crank case through "by-pass" port; (2) combusted gas is passing out exhaust port.

Fig. 2. Piston almost at top of stroke. Note two things occurring; (1) gas is being compressed and spark just about to take place; (2) fresh gas is entering crank case from carburetor through inlet port to crank case.

***Therefore with two movements of piston, one up and one down, or one revolution of crank, four actions took place; (1) intake of gas into cylinder; (2) exhaust; (3) compression and intake to crank case; (4) explosion.**

When the piston travels up, a vacuum is formed in crank case which causes the gas to be sucked in through crank case inlet port or check valve.

When piston travels down a pressure is formed in crank case (5 to 9 lbs), which forces the gas in crank case through "by-pass" into cylinder.

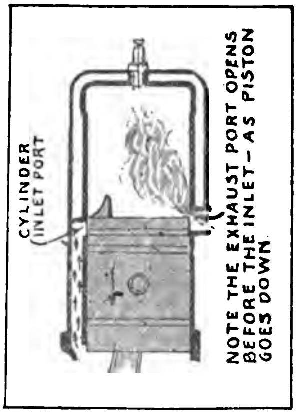

Fig. 4. Note the exhaust port on a two-cycle engine opens slightly before the cylinder inlet port or "by-pass" opens.

A "baffle plate" (D) prevents fresh gas from heading towards the exhaust.

Note when piston is down, pressure in crank case forces the check valve of carburetor to close (fig. 1). When piston is going up, the vacuum formed in crank case sucks check valve open (fig. 2.)

***On a four-cycle type of engine this would require four movements of piston or two revolutions of crank. (see page 58.)**

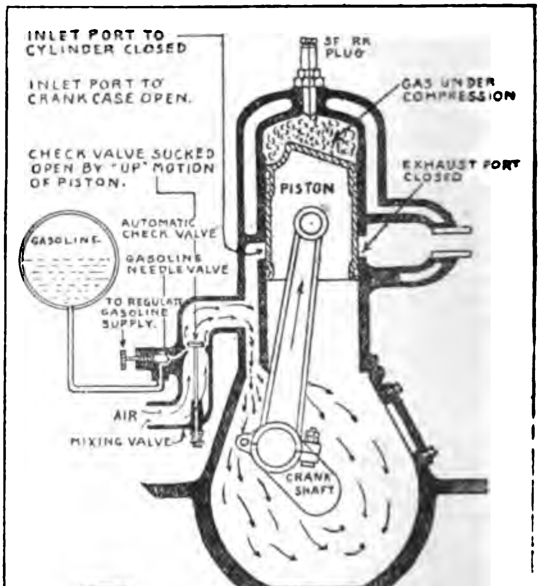

FIG.3.

Fig. 3. When a mixing valve is used the check valve is a part of the mixing valve.

When a carburetor is used with a "two port" type of engine a check valve must be used as shown above (figs. 1 and 2). A carburetor can be used however with a three port type without a check valve as the port is opened and closed by piston.

CHART NO. 312—Principle of the Two-Port Two-Cycle Type of Internal Combustion Engine.

(See page 757 for other details of a two cycle engine.) A very satisfactory two cycle engine used on a motorcycle is made by Cleveland Motorcycle Co., Cleveland, Ohio.

—continued from page 755.
reverses the direction of propulsion) in the place of a speed gear and reverse.

Stationary Gasoline Engine.

This type of internal combustion engine is usually of the four cycle type. The cylinders are large in diameter and the stroke is usually larger than the bore. The speed is slow (160 to 600) but constant.

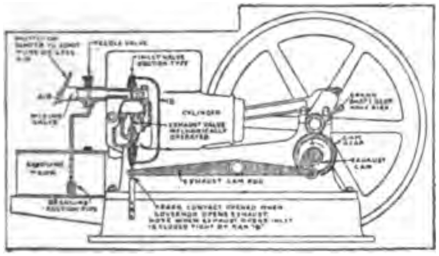

Fig 3—A horizontal engine (Witte), with a rocker arm for operating the exhaust valve mechanically. The inlet valve is automatic but when the exhaust valve is opened, note the bar (1B) closes inlet tight, although a spring is also provided.

A governor is used to keep the speed at a certain number of revolutions and it is due to the governor action on a stationary engine that you will hear exhausts at uneven intervals.

***Governors are divided into two general types**; the "hit and miss" type and the "throttling."

The "hit and miss" principle is generally used with engines using gasoline as fuel and the "throttling" type, with engines using kerosene or lower grades of fuel.

The reason why the "throttling type" governor is used with kerosene engines is due to the fact that kerosene, when used as a fuel, enters the combustion chamber almost in the form of a liquid, while gasoline enters more in the form of gas. The combustion chamber on a kerosene engine accordingly must be maintained at a fairly high temperature to properly vaporize the fuel and this temperature should also be fairly uniform.

It is the writers opinion that the reason trouble is experienced from carbon formation, where it is attempted to burn kerosene in a "hit and miss" governor engine, is because the combustion chamber on such engines cools off quite frequently during the time that explosions are cut out. This trouble, can of course, be avoided by using pre-heater in the fuel line on such engines, but this is a make-shift arrangement and not generally satisfactory. The "throttling type" governor is best as it comes nearer maintaining a uniform temperature.

The fuel may be either gasoline, naphtha, kerosene or any one of the many other petroleum products of low grades, when properly heated. Natural and artificial gas are also used.

Ignition is usually jump spark on small engines and wipe spark, page 215, or similar to the "make and break," on larger engines.

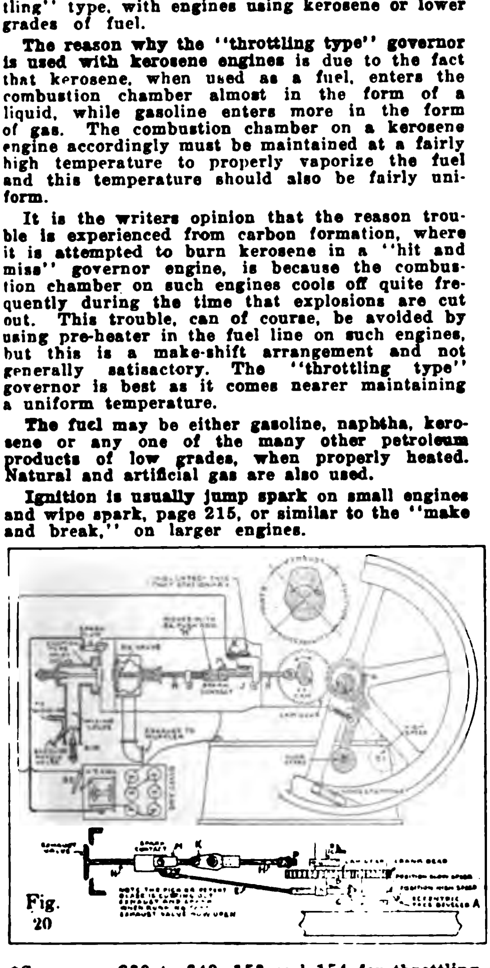

Fig. 20

On some of the engines using a low grade fuel, no ignition device is used, as for instance the Diesel engine. On others, a hot tube is preheated and serves for ignition. The latter requires complete vaporization of the fuel—all of which is covered in Dyke's Motor Manual.

The "hit and miss" governor action is shown in fig. 20. **When speed of engine increases** more than governor is set for, the ball (B), by centrifugal action, assumes position (B1). This causes eccentric sleeve (A) to allow pick-blade (E) to catch in notch part of (M). This holds open the exhaust valve and also prevents the spark contact (M) coming in contact with (K), cutting off the ignition. **When the speed decreases**, the ball (B) assumes slow speed position which causes eccentric (A) to move out from hub of fly wheel and disconnect "pick-blade" or "detent-rod" from notch in (M) and the engine fires again and exhaust valve assumes its regular work until speed increases again, at which time the same action is repeated. This cutting in and out by governor is why the uneven impulses one notices on a stationary engine.

Throttling type governor controls the admission of gas into the cylinders instead of cutting off the spark. Principle is shown on page 154, fig. 5, and pages 840 and 841.

Aero Engines.

Differ but little from the regular automobile engine, see pages 900 to 920.

**Diesel Engines.

Are used quite extensively for stationary purposes. It is also the type used on submarines. The fuel is a low grade of oil and ignition is accomplished by air compressed to several hundred pounds pressure, resulting in its temperature being raised sufficiently to ignite the fuel injected into cylinder. (see pages 758 and 587.)

Two Cycle Engine.

The two cycle type of engine is especially adapted for small powered launches, where light weight and medium power are the main requisites.

The two cycle engine is divided into three types; the "two port" which is adapted for slow speed, the "three port" high speed and the combined "two and three port," suitable for power work.

The fuels most generally used are gasoline and kerosene, and on heavy duty commercial boats a still lower grade of oil is used; but on larger heavy duty engines of this type, the four cycle principle is most generally employed.

The two cycle or "valveless" type of engine derives its name from the fact that the gas is let into and out of cylinder through "port-holes" as they are uncovered by the piston. These ports take the place of valves as used on a four cycle engine.

During two movements or strokes of the piston, the four operations of, intake, exhaust, compression and explosion occur. (see page 756.)

On a four cycle type of engine, page 58, this would require **four movements** or strokes of the piston.

The terms two-cycle and four-cycle are not appropriate. Originally the terms were two-stroke-cycle and four-stroke-cycle, and these were the more nearly correct. See page 756.

Gas Producers.

Are not internal combustion engines, but are generators of gas from hard coal, coke or charcoal.

There are two types, the pressure type and the suction type. **The pressure type** stores the gas into a tank or gasometer. The gas is then supplied to any regular type of gas engine as a fuel.

With the suction type, the gas is generated in the gas producer, then passes through a washer and is then drawn into cylinder of engine by suction of piston. See Dyke's Motor Manual.

*See pages 839 to 842, 153 and 154 for throttling type governors. **One manufacturer of the Diesel Engine is the Busch-Sulzer Diesel Engine Co., 2nd and Utah Sts., St. Louis, Mo.

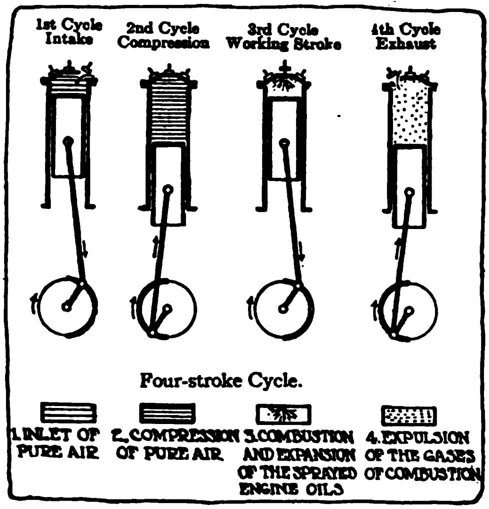

Fig. 1—Diagrammatic illustration of the principle of the four-stroke cycle Diesel.

Diesel Four Cycle Operation.

Stroke 1—Admission. During this stroke the piston travels downward and the cylinder is filled with air only—at atmospheric temperature and pressure, no fuel being introduced into the cylinder during this stroke.

Stroke 2—Compression. During this stroke the piston travels upward and the air taken into the cylinder during the preceding stroke is compressed to about 500 pounds per square inch, resulting in its temperature being raised to about 1000 degrees Fahrenheit, or sufficient to positively ignite any liquid fuel injected into it. No fuel is introduced into the cylinder until the completion of this stroke.

Stroke 3—Power or working stroke. When the piston has reached the upper end of the compression stroke (or slightly in advance) the fuel valve opens and a measured quantity of fuel oil is gradually injected into the cylinder through the atomizer which breaks it up into a finely divided spray, the orifices in the atomizer being so proportioned that at full load the admission of fuel is distributed over about 10 per cent of the power or working stroke, the rate of admission being such that there is no appreciable rise of pressure within the cylinder beyond that of compression pressure.

The quantity of fuel oil delivered to the atomizer chamber is adjusted to the various load requirements by the action of the governor upon the fuel pump.

The injection air at 750 to 950 pounds per square inch is furnished by a small two or three stage compressor, driven from the engine shaft. To prevent the possibility of preignition, this air is thoroughly cooled before being delivered to the atomizer.

When the measured charge of fuel has passed into the cylinder, and during and following combustion, the gases expand and drive the piston downward. When the piston reaches the lower end of the stroke (or slightly in advance) the exhaust valve opens and the remaining pressure is released to atmosphere.

Stroke 4—Exhaust. During this stroke the exhaust valve remains open, the piston travels upward and the products of combustion are expelled from the cylinder, completing the cycle.

Principle of the Diesel Engine.

The general arrangement of the valves and fuel injection apparatus of the Diesel motor, as illustrated in Edward Butler's book on "carburetors, vaporisers and distributing valves," is shown in fig. 2.

The cylinder C has very little clearance between the top of the piston F and the bottom of the combustion chamber B at the end of the compression stroke, at which moment the injection valve operated by the lever J will be opened, to permit the injection of a charge of fuel forced (during about 20 degrees of the crank revolution) from the supply pipe P assisted by an atomising charge of super-compressed air through the pipe D.

The cage containing the injection valve is water-jacketed, water entering and leaving by pipes W.

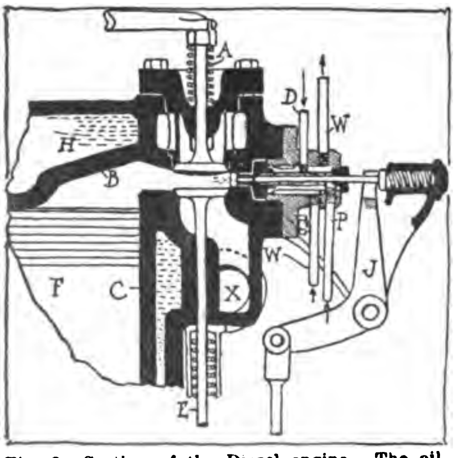

Fig. 2—Section of the Diesel engine. The oil is forced into the cylinder by air pressure.

The operation of the air admission valve A and the exhaust valve E is mechanically controlled in the conventional manner. The movement of the fuel-admission valve is very slight, giving a narrow annular opening for the entry of the oil. Surrounding the valve spindle are a series of brass washers perforated parallel to the spindle by numerous small holes.

The oil is pumped into the space around the valve spindle near its middle, and by capillary action finds its way between the washers and into the perforations.

The air for fuel injection is admitted behind the oil; and because of its high pressure, blows the oil into the cylinder when the valve opens.

The amount of oil admitted is regulated by the governor, which controls the time of opening of a by pass connecting the discharge and suction sides of the oil pump. At light loads the oil is pumped to the fuel valve for part only of the admission period, and air alone will enter past the valve for the remainder of the period.

How To Make a Service Car.

A service car is necessary in all up-to-date garages. It bears the same relation to a service station as does an ambulance to a hospital. It is a traveling representative of the service station and should impress the public that quick, clean and efficient service is given.

Any old chassis can be utilized for the purpose and by following the dimensions in table, fig. 7 a very attractive and serviceable car can be constructed.

One very important point to bear in mind is that the service wagon must be attractive in appearance—clean, well-painted, and it must run smoothly and quietly.

It will be one of the best investments you can make.

Painting: For example, cars giving Chalmers service are painted English vermillion, with black hood and running gear. Hudson service cars are white, with black trimmings. If the dealer is giving service on a particular make of car he should find if a standard service color is used. If not the car may be painted any bright color that will give distinction.

Fig. 1—After studying hundreds of service cars in dozens of the largest cities and many smaller ones, Motor World believes that a design of this general kind is best. Note particularly the method of carrying the towing pole, the jack mounting on the running board and the location of the several spot lamps.

Fig. 2—Here is a detail drawing of the body shown above. The lettered dimensions on the drawing are given in the table fig. 7; the figures refer to the location of the various tools and accessories.

Fig. 3—An alternative type of body, built especially for very light chassis, often is desirable, in which case the arrangement can be made something like this. This is a body that is used quite successfully by the Chevrolet company in Detroit. There is an almost endless variety of arrangements, and in laying out a car a shop foreman should be guided by the particular class of work he expects to be called upon to do.

Fig. 4—This is a view of the interior of the service car shown in fig. 1. Note the chocks and the neat arrangement of the tools, the seat at the right not being shown, so that the compartments are visible.

Fig. 5—This is a detail drawing of the jack mounting shown on the service car illustrated in fig. 1. In this case 5-ton jacks are carried, though any size can be substituted. Get them big enough to care for the heaviest work to be done and they will also serve for light work.

Fig. 6—The service jacks can be carried bolted to the running board, like this, thumb-screws being used for quick action.

Fig. 7—This table of dimensions, which is to go with the drawing fig. 1, has been compiled after a careful and critical study of hundreds of service wagons. The figures given are intended to be for average requirements of the average service car built on the various chassis which are listed in the table.

CHART NO. 318—A Service Car; How To Construct. (See pages 821 and 822 for converting Ford car for Commercial use.)
(From Motor World, by Mr. S. Thornton Williams.) See page 732, "Towing in a Car."

Re-Designing and Speeding Up Old Cars.

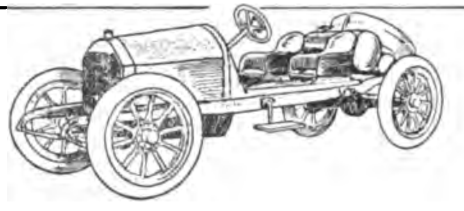

Fig. 1—Usual form of racy roadster with bucket seats

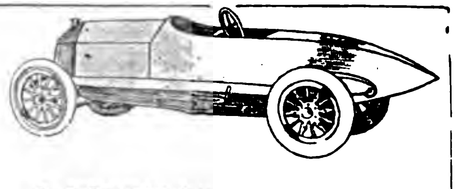

Fig. 2—Type of body designed for minimum wind resistance

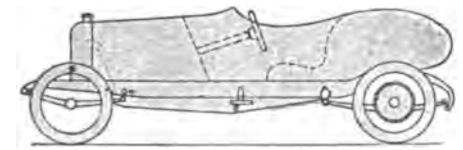

Fig. 3—A suggested body design for class and wind resistance lowering

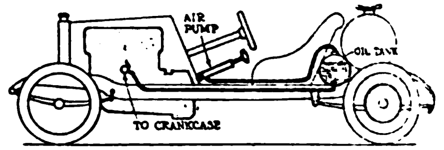

Fig. 4—One way to fit auxiliary oil system when tank is at rear

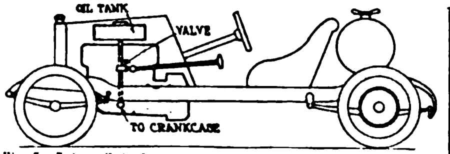

Fig. 5—Extra oil tank at top of motor, supply from which is controlled by a valve

Generally speaking, the replacing of the old body with a raceabout type is the most important consideration in rejuvenating an old one, but usually the steering column has to be lowered and sometimes a leaf removed from each of the springs to make up for the lighter body, although this latter is not essential by any means. All too often, old cars have springs that are too weak for the heavy bodies with which they were originally burdened, and these prove just about right for the lighter bodies.

Changes in the valve timing are often made to assist in the speed possibilities, and sometimes different axle gears are used so as to raise the ratio between engine and wheels. It must be borne in mind, however, that many chassis and engine changes of this kind will work to the disadvantage of the car for slow running. They will serve to make the machine faster, but they hamper the engine's ability at low throttle running. In other words, it will not have the flexibility on high gear.

Body being the first consideration in making a speedster, it might be well to take up some of the possible designs. For Fords* the combinations offered by concerns making a business of this kind of work are indeed attractive. You can get a complete outfit of radiator, hood, floor boards, rear gasoline tank, and body in the neighborhood of $100, and it is surprising what a difference these make. Other concerns make a specialty of the body proper exclusive of radiators, hoods, tanks, etc., and it is also possible to get bucket seats alone, so that, with a little ingenuity quite a presentable racy-roadster can result from combinations with old chassis.

Dressing up the cars: The illustrations herewith are suggestions as to how to dress up the chassis in several ways. Many of the most attractive of the types that have come to our attention have been made by enthusiasts, with the assistance of a tinner or other tradesman of similar experience. The usual form of racing roadster is shown in fig. 1.

This has bucket seats that are attached directly to the floor with gasoline and oil tanks and tires carried at the rear in a way that adds to the appearance. The dash is sloped slightly, and the steering wheel brought down so as to make steering easy with the seats in this low position. Sometimes running boards and mudguards are entirely eliminated as shown, with steps at the side to assist in getting into the car, while often the owner prefers to have the mud-guards as a matter of protection. They retard the speed a little where fast driving is the thing most sought, but it is a question if they do not also add to the appearance. Usually the hood is sloped somewhat as an added feature. Undoubtedly a high, narrow radiator (page 190) also does its part in improving the looks, but this is carrying the alterations to quite an extreme.

**Wind resistance is quite a factor in hampering the speed of a car, far more of a factor in fact, than most motorists realize. To attain greatest speed, the head resistance, by which is meant the surface against which the wind strikes, must be made as small as possible, and the body must be so smooth along its length that there are no obstructions against which the wind can strike and thus form eddies. In other words, the air should be allowed to slide along the body without having to come in contact with lamps or other obstructions.

Getting streamline effect: This is the streamline idea, and in order to carry it out best, the radiator should be as narrow as consistent with proper cooling, the hood should slope, and the rear should taper. If a taper tail is fitted, this forms the most perfect form of body so far as wind resistance is concerned, providing the rest of the body conforms with it. Tires and gasoline tanks obstruct the air, and wherever possible they should be placed within the tail, if one is fitted. It is not always easy to keep some parts from offering wind resistance, for generally the spare tires have to be carried outside. Two body designs that carry out the wind resistance reduction theory very well are shown in figs. 2 and 3.

Thus, even if the engine and gear ratio are not altered at all, more speed is obtainable by cutting down the wind resistance and fitting the lighter body. Usually from 10 to 15 miles per hour is added to the possibilities of the vehicle by these changes alone and sometimes, with engine specially tuned for speed work though timing and valves are not altered, it is possible to get even more. The reduction in wind retardation, however, permits of raising the gear ratio sometimes where it would not be practicable to do so otherwise. Often if a car is fitted with a standard ratio of 4 to 1, say, this can be raised to 3 to 1, if the other factors have first been changed.

Some of the mechanical points that can be changed are the carburetor setting, adjusting it so that while it may not allow the engine to throttle down so well, it works better at the higher speeds. Usually this is the result of making the mixture leaner, and it ordinarily has the added advantage of preventing the engine from getting so hot.

The magneto or other ignition apparatus can also be altered to conform to the higer speeds, this usually being a matter of setting the timing ahead a slight amount, the exact extent of which depends entirely upon the engine.

More power, and consequently more speed, is often obtainable by reducing the vibration through accurately balancing the pistons.† In other words, a set of pistons of exactly the same weight should be used if possible. Often speed bugs have gone so far as to drill the connecting-rods in order to

CHART NO. 314—Re-Designing and Speeding Up Old Cars. (From Motor Age.)

*See also Ford Supplement. **See also, page 587. †See also, pages 818, 813, 792

—continued from chart 314.

lighten these reciprocating parts as much as possible, but this ordinarily is not advisable, for the rods are undoubtedly weakened thereby, and not being designed for such treatment, they often will not stand the strain (determined by amount of stock in rods).

Extra lubrication is often advisable where the owner wishes to maintain excessively high speeds for any length of time. This can very simply be attained by rigging up an auxiliary supply that will feed directly into the crankcase. An easy scheme to employ is shown in fig. 4, chart 314. A hand pump is pivoted to the floor of the car as indicated, and an air line runs from it to the top of the oil tank at the rear. The delivery pipe from the oil tank to the crankcase runs from the lower side of the tank, and thus the air pressure due to the hand pump forces the excess oil to the engine.

Sometimes an auxiliary oil tank is fitted to the engine and under the hood if there is room. There is a pipe connecting from the bottom of this to the crankcase, and a valve is interposed in the pipe to allow of controlling the oil from the seat by means of a rod.

Such auxiliary devices as these and the altering of the camshaft and valves are extremes to which the average man cannot go, although they are conducive of surprising results where intelligently carried out. (see Ford Instruction.)

Fig. 2—An exclusive MOTOR AGE design for a four passenger touring roadster

Racing Car Exhaust Effect.

Fig. 6—The low rumble in the exhaust of a racing car is due generally to the design and construction of the engine. One method to obtain this effect is to magnify the sound as in fig. 6. This shows a large sheet steel cylinder, A, fitted with a conical-shaped head into which the exhaust pipe is led as shown. The end of the exhaust pipe should be flared, as shown at B. The rear end of the cylinder A is covered with a metal cap into which several holes have been made.

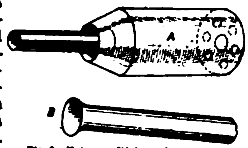

Fig. 6—Noise amplifying exhaust to give racer sound to small engines

We have seen this arrangement used very successfully on a small high-speed engine, the exhaust of which sounded like a high-powered racing car. Many of the racing cars give out a metallic sounding exhaust because the exhaust pipes and headers are made of thin metal. This thin metal will vibrate under the periodic exhaust impulses and set up a peculiar ring of its own. Of course, the thinner the exhaust pipe the better will be its radiating effect.

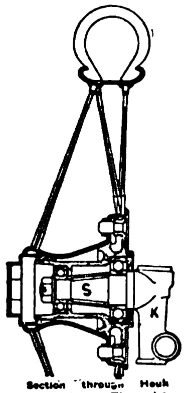
Addresses of Body Builders.

Following are the addresses of a few concerns who specialize in bodies made to order: Charles E. Schutte, Lancaster, Pa.; Auto Remodeling Co., 1501 Michigan Avenue, Chicago; Detroit Auto Products Co., 38 Sherman Street, Detroit; Lehman Mfg. Co., Cannelton, Ind.; Auto Sheet Metal Works, 2301 South Wabash Avenue, Chicago; Wright, Cooler & Hood Mfg. Co., 4867 North Clark Street, Chicago, etc. Submit sketches for quotations from the above concerns.

Note. Above names secured from trade magazine advertisements.

CHART NO. 314-A—Re-Designing and Speeding Up Old Cars—continued.

The different methods employed are shown in the dotted lines. For instance in the Buick model 30, the idea is shown whereby bucket seats are installed and a cowl is built around the seats. The gear ratio is changed to 2¾ to 1.



Section through Houk wire wheel. The wire wheel hub is shown in black

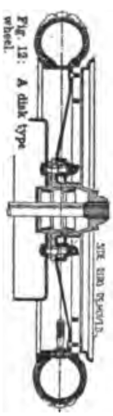


Fig. 12: A disk type wheel.

Fig. 12

Wheels.

Wheels are divided into four classes: Wood, wire, disk and steel spoke wheels. The latter type being confined to motor truck use.

The wood wheel predominates but does not possess the lasting qualities of metal, and costs less.

If wood spokes become loose and squeak, the cause is usually due to dryness, from lack of washing. To remedy, swell spokes by soaking well with water. **If this fails,** try plan per page 810. **When wood spokes break,** new one can be fitted.

Wire wheels are lighter and are generally of the demountable type. The triple spoke construction is the favored type.

When wire wheel spokes break or become loose new ones can be inserted or loose ones tightened similar to bicycle spokes. **Hub caps on wire wheels** must be tight, otherwise there will be an intermittent clicking noise.

Disk wheels are now popular and add considerably to the appearance of a car. The steel disk is usually dished and welded or bolted to the felloe. The hub is usually bolted to the disk. See also, fig. 12.

Manufacturers of wire wheels: Houk Mfg. Co., Buffalo, N. Y.; Great Western Wheel Co., La Porte, Ind.

Adjusting Timken Worm Drive Truck Axles.

To adjust worm: Bearings on either end of worm shaft are set to allow a slight end play which is taken up by expansion of the worm when in operation. **If end play is too great,** causing excessive wear in bearings, adjust by means of cup "A", fig. 1. First loosen bolts "C" and "D", next remove lock "B" and turn adjusting cup "A" towards left (as you sit in car) until end play is approximately .015".

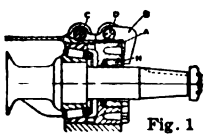

Fig. 1

To adjust differential bearings, remove carrier from housing. Loosen cup bolt "F" (fig. 2) and lock "G", then turn adjusting ring "E" until properly adjusted. **Make adjustments on left-hand bearing only.** Do not touch right-hand differential bearing, as it will disturb proper meshing of worm and gear.

Wheel bearings are adjusted so that when you grasp rim of wheel at top and bottom in a perpendicular line you can feel a barely perceptible shake.

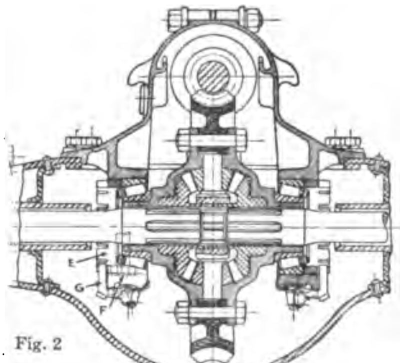

Fig. 2

Examine wheel bearings in hub about every 5,000 miles and see if properly adjusted and lubricated. **To lubricate wheel bearings,** fill hub full with a light grease, free from acid and grit.

To lubricate worm and worm gearing fig. 3: Remove filler cap and pour in oil until level with opening. Examine condition and amount of oil weekly. If it contains grit or is so thick it will not circulate, drain housing by unscrewing plug at bottom. Run kerosene through to cleanse, then refill with oil.

The worm wheel revolving in the oil carries it to the upper part of housing fig. 4. The worm in revolving throws the oil to the sides where it is caught by troughs marked by arrows. The oil runs by gravity to front and rear of housing and is drawn through the bearings by their pumping action and from there flows back to starting point.

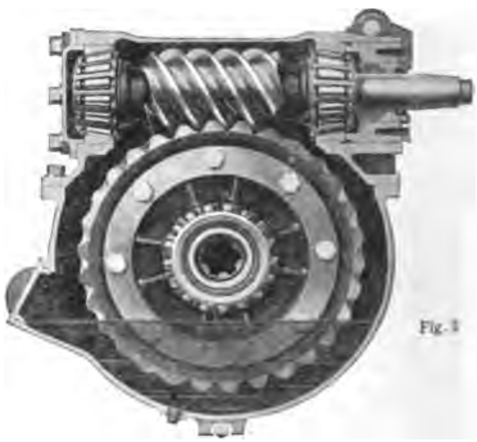

Fig. 3

Once every month remove axle housing plate and clean out the oil ducts with a wire. Although the housing is dirt proof the oil may become so thick it will not circulate. **When replacing housing plate** coat the washer on it with shellac and tighten all bolts.

Occassionally an axle will leak oil at forward end of worm shaft. If so, draw up on packing gland "H", fig. 1.

Oil to use: Do not use oil which will clog the oil passages. Use only high grade oil, free from acid and grit and that will stand a cold test of zero or below.

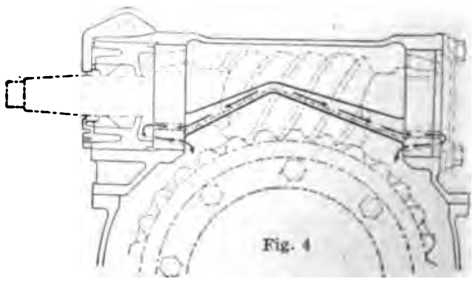

Fig. 4

CHART NO. 315—Wheels. Timken Worm Drive Truck Axles. No. 6456, 1 ton; Nos. 6551-6552, 1½ and 2 ton; Nos. 6650-6652, 3 and 3½ ton.

Timken-Detroit Axle Co., Detroit, Mich., Manufacturers.

The Stanley Steam Car.

Engine—double acting, taking steam at each end of cylinder. Slide valve—built in a unit with rear axle and driving through a spur gear on differential (GD) (fig. 8). Crank shaft spur gear (DG) is the drive gear on engine.

The valves which control the admission and exhaust, are operated from eccentrics on the crank shaft and through a link motion (LM), through (LSS) which is connected with left pedal (fig. 2) and controls the range of motion of the valve.

There are three passages when the valve is open for a large part of the stroke. This admits steam at boiler pressure and shuts the valve a certain distance before the piston reaches the bottom of its stroke. For the rest of the traveling the piston is driven by the expansion of the steam. Pressing the pedal (T) forward until it catches or hooks up causes the valve to close earlier. This means that less steam is taken from the boiler and the piston is driven a longer distance by the expansion. This, of course, is more economical of steam and the condition for normal running.

The longer valve opening is used for starting and practically for nothing else. With the pedal pressed forward the operation of the valve is reversed so that the engine will run backwards, this giving the reverse motion.

After leaving the engine, the steam goes to feed water heater thence to the top of the radiator, upon passing through which it condenses into water and this water flows back to the main tank. Differing load and road conditions entail the loss of some steam, and it is this loss which has to be made up by refilling the water tank. However, sufficient water can be carried for 200 to 250 miles of ordinary running, or, in other words, it takes this amount of ordinary running before the slight loss of steam is equivalent to the whole tank full of water, which is about 20 gal. and is placed underneath the car, below frame.

Boiler—Fire tube type. The flues being welded by the acetylene process to the bottom head.

Burner—Just as we have to open the throttle when we want more power from the gas car, so do we want more heat from the burner when we want more power from the steam car.

How kerosene is used: The kerosene under pressure is first led through a long coil placed on top of boiler, where the exhaust gases of combustion yield up part of their waste heat, by preheating the kerosene. From this top or heating coil the kerosene passes by way of the automatic control and main burner valve to the vaporizer (located in the fire) here the hot kerosene is transferred into a true gas and after being mixed with a definite amount of air is burned with the blue "Bunsen" flame.

Questions Answered Relative to the Stanley Steam Car.

(Q-1) Where is the engine located?

(A-1) The engine is located on the rear axle and supported from the rear axle differential housing. It is swung at other end, from the car frame by means of a spring strap hanger.

(Q-2) How does engine drive rear axle?

(A-2) The engine frame made up of four members, are carried through the differential housing, turning in an oscillating block at that point. Thus the engine and rear axle become a unit. The gear teeth of the engines main drive meshing with those of the differential.

(Q-3) What is the ratio of gearing?

(A-3) This depends upon the size, power and type of car employed, in the older models it is 2:1 and in the later models 1½:1.

(Q-4) Where is boiler located?

(A-4) The boiler is located in front of the dash, underneath the hood and behind the condensor which is also a radiator.

(Q-5) What steam pressure is usually carried?

(A-5) All stock cars, regardless of model operate on 600 pounds pressure normally. However for speed purposes this pressure is run up as high as twelve hundred to fifteen hundred pounds.

(Q-6) What is the average time required to raise sufficient steam pressure when cold?

(A-6) The initial time of steaming a car when cold will take approximately fifteen minutes. This includes filling of the tanks and boiler, as well as the raising of steam pressure.

(Q-7) What time if standing awhile after having been used?

(A-7) No time whatever required for raising running pressure. Inasmuch as that pressure has been maintained.

(Q-8) What is the fuel consumption?

(A-8) One of the Stanley five passenger, big touring cars was run for three consecutive months, making an average of twelve miles per gallon of coal oil. On long runs, this figure is increased as high as sixteen or seventeen miles per gallon of coal oil.

(Q-9) How are the various speeds controlled?

(A-9) From zero to the world record, is obtained by the opening of the throttle, the handle of which is located on the steering wheel. There is no other movement on the part of the operater for increasing or retarding his speed, other than the throttle.

(Q-10) What is the water capacity and consumption?

(A-10) The water capacity is 20 gallons carried in a tank, beneath the car frame and filled through a radiator. This capacity is sufficient for a days run. We have known it to go as high as 350 miles.

(Q-11) Mention the control levers, valves, etc.

(A-11) When starting out with a car, a valve is opened which places the car under automatic control from that time on. When brought to a stop, this valve is closed. The operating controls are the throttle, the service and emergency brakes and reverse.

(Q.12) Where are control parts located?

(A-12) The throttle subimposes on steering wheel. The foot brake, usual position. Reverse, a foot brake. The emergency, a handle brake, located on the side of the car.

(Q-13) What are the advantages of a steam car?

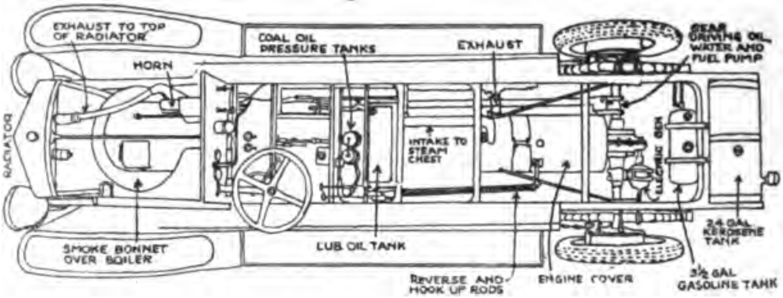
(A-13) Entire lack of vibration; freedom from gear shifting; absence of clutch; absolute flexibility; more power per weight than is possible in gasoline cars; a car that cannot freeze up in winter weather; simplicity of controls, but 32 moving parts, counting the wheels, low cost of upkeep; greater tire mileage; small depreciation factor; no smoke or steam visible in cold weather.

(Q-14) What are its disadvantages?

(A-14) These have in later models been overcome, but formerly they were: shape of hood; necessity for firing up; likelihood of freezing; nenessity of taking on water every fifty miles (before condensing system used); steam in street.

Note:—The above questions were answered by Mr. M. H. Ward of the Stanley Motor Car Co. of St. Louis, Mo. Mr. Ward also supplied other data for this subject.

Fig. 1—Plan view.



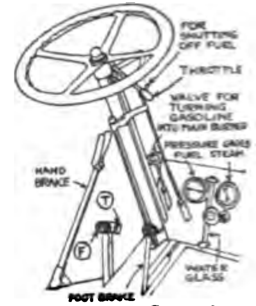


Fig. 2—Control.

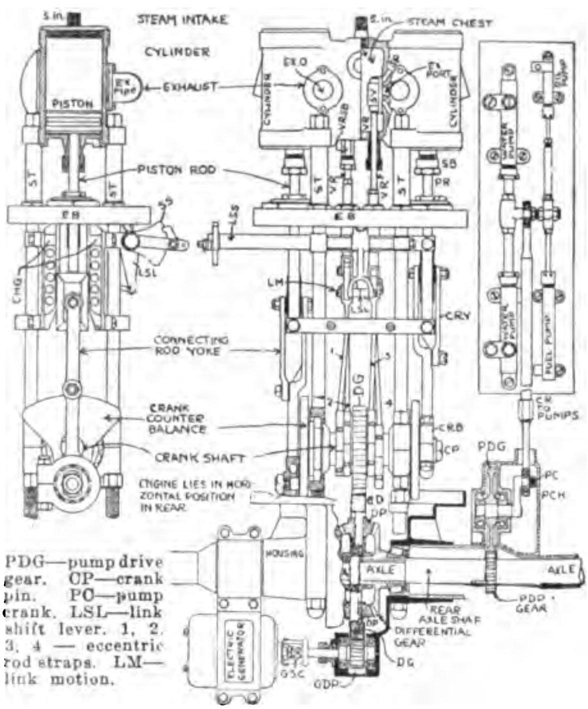
Fig. 2—Control of car: The left pedal gives the two valve positions for forward running and the reverse. (T) is pressed forward half way after starting and left there. (F) is the reverse pedal, and is pushed full forward when car is reversed. The right pedal operates the service brake, the lever, the emergncy brake. The throttle is the only control used while running. A little lever partly concealed by the throttle lever, is for shutting off the fuel when making a long stop. When starting from dead cold, the valve turning gaseline into the main burner is used. On dash the left gage shows the fuel pressure and is seldom looked at. The right gage is the steam pressure. In the center is the water glass that is only carried as an emergency indicator in the event of any trouble in the water feed system.



PDG—pump drive gear. CP—crank pin. PC—pump crank. LSL—link shift lever. 1, 2, 3, 4 — eccentric rod straps. LM—link motion.

Fig. 3—Stanley engine, rear axle and pump gear. The pumps are really mounted forward on chassis and are driven by a crank off rear axle. Electric generator also rear axle driven.

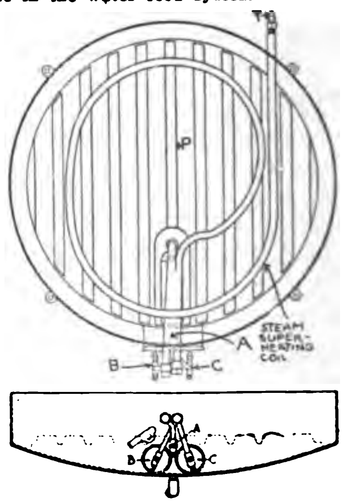


Fig. 4—Stanley Burner—A is the gasoline nozzle for the pilot light and B & C the two main burner nozzles for coal oil or main fuel.

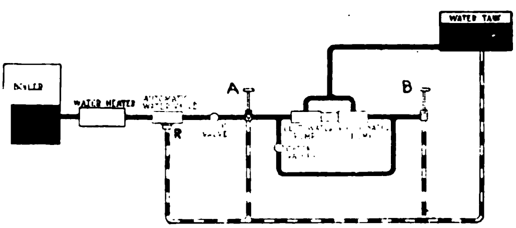

Fig. 5—Diagram of water system of Stanley steam car. Water is pumped towards the boiler by one or two pumps, according to the positions of the hand valves A and B. After reaching a proper level in the boiler the release valve R is opened and the water then goes back to the main tank, whether the pumps are both working or not. In practice the left pump always is in use subject to the automatic control, and the right pump is hardly ever called into service, but doubles the supply for emergency use.

Uniform water level; when water reaches a certain height, it is forced to return to the supply tank, by an automatic by pass, thermostatically operated.

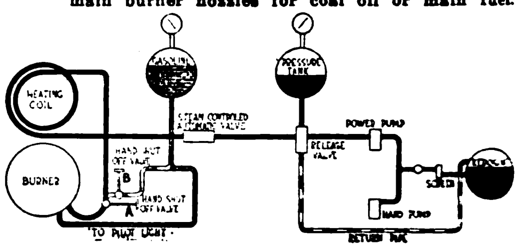

Fig. 6—Diagram of fuel system of Stanley steam car. The gasoline only supplies the pilot light which never goes out and the consumption is small, so the size of the tank is exaggerated in the cut. Kerosene, the operating fuel, is carried in the rear tank and pumped to the pressure tank from which the burner takes its supply. When the steam pressure reaches a predetermined point the supply of fuel is cut off and the kerosene pumped is allowed to go back to the main tank. The heavy black line in the cut indicates the kerosene supply, the broken black line the return lines for surplus, and the grey lining gasoline.

CHART NO. 316—The Stanley Steamer. DG—spur drive gear on engine; GD—differential gear in mesh with it; DP—differential drive pinion; DG—(lower) differential gear mesh with generator; CR—connecting rod; CRY—connecting rod yoke; SV—slide valve; CHG—cross head guides.

The Doble Steam Car.

How the Doble Differs from the Stanley.

1st—Doble boiler is of the water tube type. Stanley boiler is of the fire tube type.

2nd—Doble boiler consists of 28 sections, placed in an insulated casing, Stanley boiler is in reality a big drum standing over the burners.

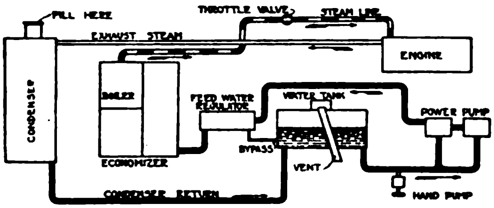

Fig 3—Water and steam piping diagram of the Doble steam car. The cycle of operations is as follows. Water put into the condenser flows to the water tank by gravity. It is pumped by a power pump through the regulator and economizer into the boiler, where it is changed to steam. Steam from the boiler passes through the throttle into the engine, thence to the condenser, where it is reduced to water again

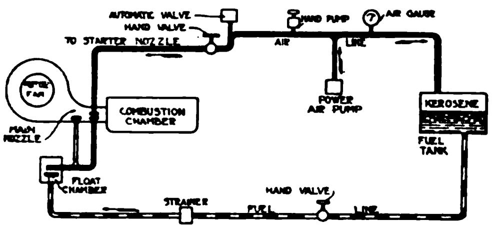

Fig 4—Air and fuel piping: Air pressure of 2 lb. per square inch is maintained in the fuel tank. The blower motor is started through a switch, after which speed is regulated automatically by the steam pressure

3rd.—Doble has no pilot light, (mixture ignited by electric spark.) Stanley has only a pilot light for ignition.

4th—Doble uses kerosene for both starting and running. Stanley uses gasoline for starting, kerosene for running.

5th—Doble slide valve used only for admission of steam to engine cylinder. Stanley slide valve regulates both admission and exhaust.

6th—In the Doble the exhaust steam goes direct to radiator. In the Stanley the exhaust passes through a feed water heater before it goes to the radiator.

Features of the Doble.

Sectional boiler; 20 sections used for generating steam and 8 sections used for feed water heater or economizer.

Absence of pilot light: This is a radical departure from the usual construction.

Kerosene for starting; as well as for running.

Wide pistons; necessary on account of pistons having to open and close exhaust port (similar to a 2 cycle gasoline engine) and is termed the uniflow principle.

Absence of eccentrics; valve gear is a modified form of the "Joy valve gear" in which modification the "correcting" and "anchor links" are eliminated, thus simplifying the construction.

Final drive (gear ratio) is almost 1 to 1, viz: 47 teeth in drive gear and 49 in differential.

A condenser is provided so that the steam is reconverted into water—and used over and over again.

Lubricating oil is mixed with the water for lubrication of cylinders.

A Motor Bob—Wheel Drive.

Riding board 14" wide x 1¼" thick. 2—7" strips may be used, but a single plank is best. Two 1x3" pieces trengthen it. Two **running boards** hung on steel brackets offer foot rest for passengers. Sleds should be made of hard-wood with steel runners.

Engine motorcycle type. Mounted in frame of ⅝" round stock per fig. 3. Weight of bob is not carried on the wheels, therefore two heavy coil springs forces wheel to ground (fig. 1), by pull on frame.

Also note the skid chain on motorcycle wheel to give it traction. Steering is shown in fig. 2.

Propeller Drive

is shown in fig. 4. Not recommended for narrow gage bobs. Has advantage over the wheel in that wheel has difficulty of obtaining traction in soft snow or broken roads. Better ask some aeroplane propeller manufacturer if propeller is used, as to revolutions and size.

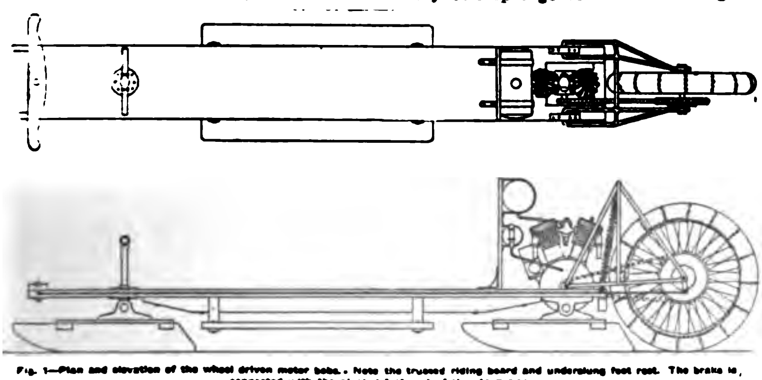

Fig. 1—Plan and elevation of the wheel driven motor bobs. Note the trussed riding board and underslung foot rest. The brake is, connected with the pivoted foot rest of the steersman

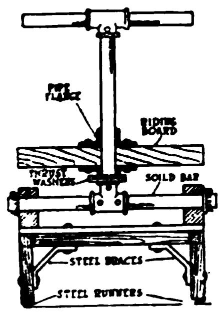
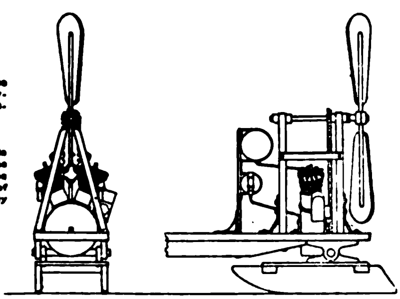


Left—Fig. 2—Detail of the front bob mounting, showing the steering mechanism

Right—Fig. 4—A simple method of mounting the propeller at the rear. The standards are made of 2-in angle irons, rigidly braced



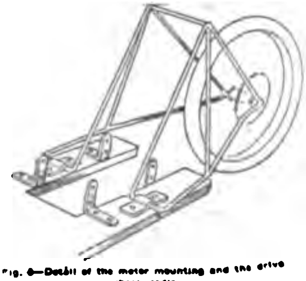


Fig. 6—Detail of the motor mounting and the drive wheel cradle

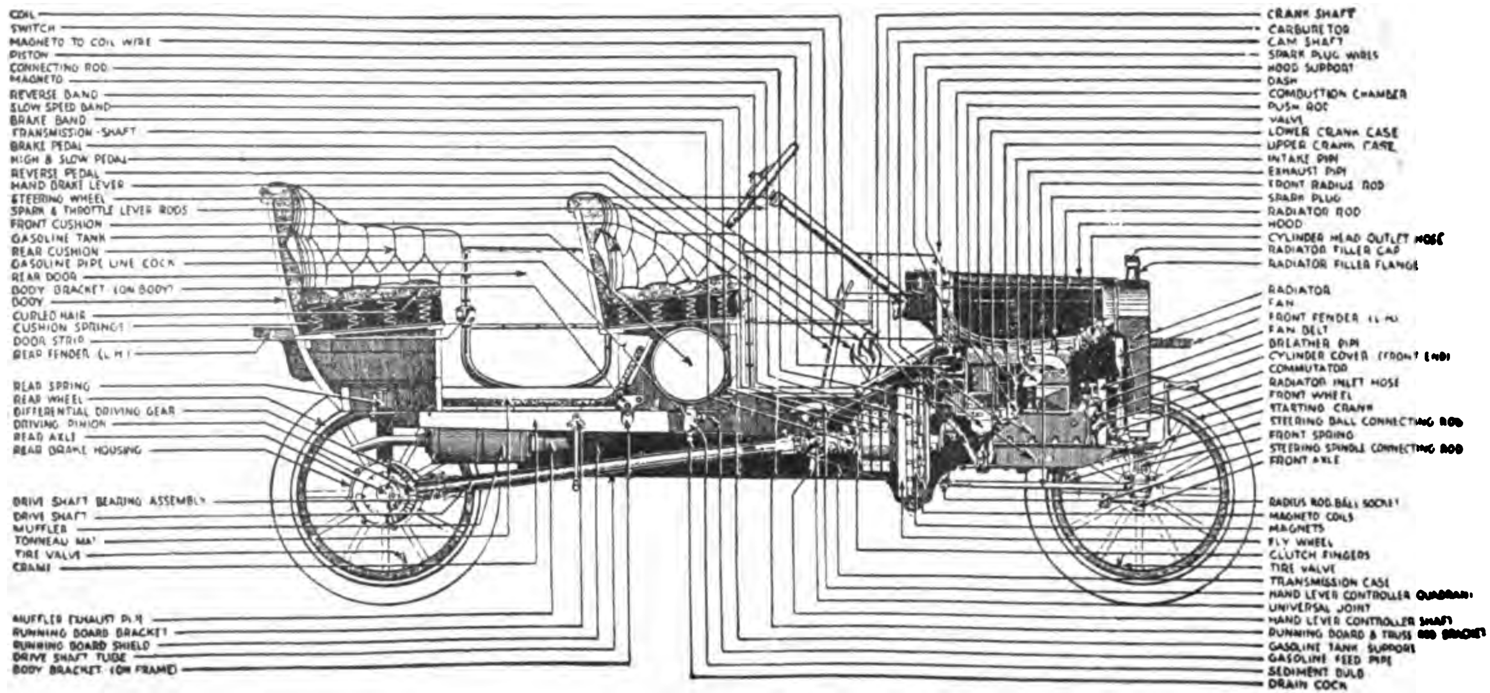
CHART NO. 316A—Doble Steam Car. A Motor Bob. (Automobile.)

The Doble steam car is manufactured by the Doble-Detroit Steam Motor Car Co., Detroit, Mich. Stanley, by Stanle Steam Car Co., Newton, Mass.



Specifications of Ford Car.

Axles; (front) I beam drop forged from Vanadium steel. **Rear axle;** semi-floating enclosed in a tubular steel housing. **Differential,** three pinion type.

Bodies are in 5 styles; runabout, 2 passengers; touring car, 5 passengers; coupelet, 2 passengers; town car, 6 passengers; sedan, 5 passengers.

Brakes; dual system. "Running" or "service" brake on transmission controlled by the foot. "Emergency" or "hand brake" is the expanding type in drum of rear wheels. Controlled by hand lever on left side.

Clutch, multiple steel discs operating in oil. Control—On the left side of car. Three foot pedal controls, low and high speeds, reverse, and brake on the transmission. Hand lever (for neutral, and emergency brake) on left side of car. Spark and throttle levers directly under steering wheel.

Cooling—By thermo-syphon water system. **Lubrication;** gravity and splash, see pages 772 and 197. Oil is poured into crank case through breather pipe on front cylinder cover.

Ignition, see pages 803 and 265. Gasoline capacity 10 gallons.

Engine, 4 cylinder, four cycle 3¾ bore x 4 inch stroke. 22.5 S. A. E. horsepower rating. Cylinder head detachable. Cylinders enbloc. Lower half of crank case one piece pressed steel. All interior parts reached by removing plate on bottom of crank case. Three point suspension of power plant. Valves on right side of engine.

Springs, semi-elliptic.

Transmission; spur planetary gear type.

Wheels wood artillery type. **Wheel base,** 100 inches. Standard tread 56 inches. Cars will turn in 28 foot circle. Tires 30x3 front, 30x3½ rear, clincher type.

Later Changes on Ford.

(1) fitting of a new style radiator; (2) sloping hood; (3) crowned fenders; (4) fan with shield around it; (5) electric vibrator type horn operated from magneto; (6) speedometer bracket no longer fitted; (7) 60 inches or "Southern" tread, no longer made.

Cost of Operating a Ford.

Gasoline, 22 miles per gallon; **Lub. oil,** 400 miles per gal. Tires average 4000 to 5000 miles. City license $3. State license $3. Summing up, say for 4000 miles running would have; 182 gal. gas, at 25c, $45.50; 10 gal. oil at 50c, $5.00; license for one year $6. Tires and tubes 2, at $14 and 2 at $17, $62. This would make a total of $118. for 4000 miles. If 150 miles per week was averaged this would make a cost of $112. for 26 weeks or $18.50 per month. Washing and storage extra if kept in a garage. (Figures approximate).

CHART NO. 317—Sectional View of the Ford Car Showing the Names and Location of Parts.

FORD INDEX—Continued.

(Illustration on page 766 courtesy of ''Fordowner.'')

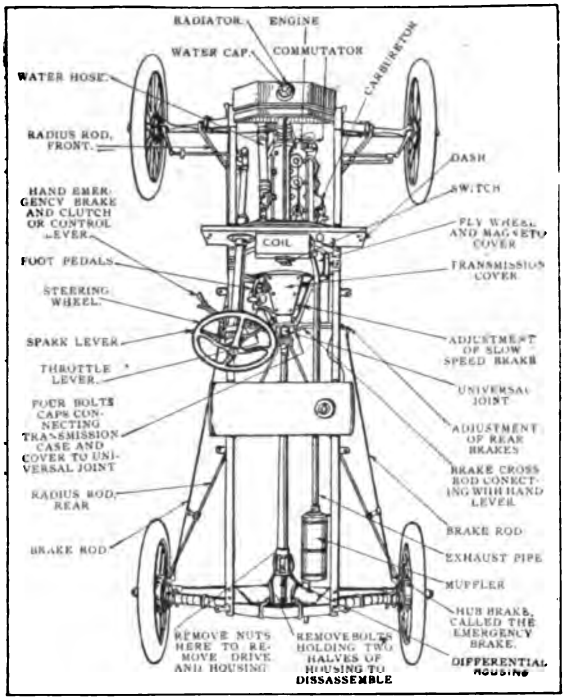

Fig. 2—Chassis.

Construction.

The Ford chassis is divided into units—such as; the front axle system; the rear axle system; the engine and transmission unit; and the dashboard, which includes the steering column. It is well to remember these units when making repairs to cars, for it often is necessary to remove the entire unit from the car when a certain part is to be repaired. For example; when repairing an axle shaft, it is necessary to remove the entire rear axle system, in order that shaft may be removed.

FORD TORQUE AND H. P. TABLE

R. P. M.	Speed in miles per hour: Car	Speed in miles per hour: Truck	Pounds Torque	Horsepower
300	7.5	4	35	2
400	10	5.25	57	4.5
500	12.5	6.55	69	6.5
600	15	7.9	73	8.5
700	17.5	9.2	78	10.40
800	20	10.50	81	12.35
900	22.5	11.85	83	14.30
1000	25	13.15	82	15.60
1100	27.5	14.50	81	16.66
1200	30	15.80	79	18.30
1300	32.5	17.10	77	19
1400	35	18.45	73	19.66
1500	37.5	19.75	70	20
1600	40	21.05	65	20
1700	42.5	22.40	60	19.40
1800	45	23.75	53	18.30
1900			47	17

The torque and horse-power figures were obtained with a wide open throttle. They represent only the maximum power that can be developed at the given speeds. As the throttle is seldom wide open when driving car, speed is rarely indicative of the horse-power the engine is developing. Notice the torque (pounds pull) begins to drop off at 900 r. p. m. The engine exerts its greatest pull at this speed—see page 535.

Ford Data—Condensed.

	*1918 1919	1917	1916	1915	1914	1913
Touring	$525	$360	$440	$490	$550	$600

cam gear diameter ....5⅓ in.
crank shaft gear ....21 teeth
crank shaft gear diameter ....2⅔ in.

‡Magneto Speed and Voltage.

The Ford Magneto varies in voltage, amperes, and cycle, with the speed of the engine. Table gives the variation compared to the speed in the engine and the speed of the car and truck:

R.P.M.	Miles per hr. Car	Miles per hr. Truck	Volts	Amperes	Cycle
100	5	2.63	5	6.1	26.4
400	10	5.26	9.8	7.9	52.8
600	15	7.89	14.4	8.5	80.0
800	20	10.52	18.8	8.8	106.[illegible]
1000	25	13.15	22.8	8.9	146.4
1200	30	15.8	26.2	9	160.0

Lamps are connected in series—see foot-note, page 812.

Speed of Engine to Car.

Drive shaft pinion—bevel gear 40 teeth. Low speed ratio, 10 to 1. High speed ratio, 3 7/11 to 1. **Reverse ratio, 14.5 to 1. Rear Wheels, 30".**

To find the speed in miles per hour:

Eng. speed per min.	mi. per hr. reverse	mi. per hr. 1st speed	mi. per hr. high speed
500	3.892+	5.589—	12.295+
600	4.761+	6.706—	14.754+
1000	7.784+	11.178—	24.590+
1500	11.676+	16.767—	36.885+

Brakes.

Brakes on hub of rear wheels have cast iron shoes, size 7⅝ x 13/16 x ⅛. Brakes controlled by side hand lever. **Brake on transmission,** controlled by foot.

Size of brake, low speed and reverse drum lining on transmission can be 1/16" or 11/64" thick, 1⅛" or 1 3/16" wide and 28 3/16" or 28⅝" long. See page 777 for dia. of drums.

Tread and Wheel Base.

Wheel base, 100 inches. **Tread,** 56 inches.
(60 inch, or Southern tread, is no longer made.)

Engine Numbers.

Cars are recorded by engine numbers, rather than by car numbers and the numbers of engine and car are not the same.

Year 1912	88,900	to	171,300
1913	171,300	to	370,400
1914	370,400	to	611,100
1915	611,000	to	1,029,200
1916	1,029,200	to	1,614,600
1917	1,614,600	to	2,449,100
1918	2,449,100	to	2,831,400
1919 (to Sept. 30)			3,429,400

These numbers stamped on left-hand side of cylinder block, above inlet hose connection.

Cooling System.

Thermo syphon principle. Radiator capacity 3 gal., 7½ pints; former radiator, 3 gal., 1¾ pints.

Radiator hose—inlet 1¾ inch, 3 ply 2¾" long. Outlet 2" int. dia., 4 ply 3¼" long.

Hose bands are 2⅛" and 2½" inside diameter.

Horse Power.

S. A. E. rating of engine 22.5—see page 534.

HART NO. 318—Ford Chassis. General Data.

Without war tax. Price of truck $550—see page 825. ‡See p. 812, foot note and 823. †See page 864C for prices on Ford Enclosed cars with Electric Starter. **A—without starter equipment. B—with starter equipment. If touring cars and runabouts are equipped with demountable rims, add 18 lbs. If with 5 demountable rims, add 29 lbs., if with tire carrier, add 18 lbs. ‡See foot note, page 776 for later exact overall dimensions and smallest size garage to house a Ford and page 821 for Chassis dimensions.

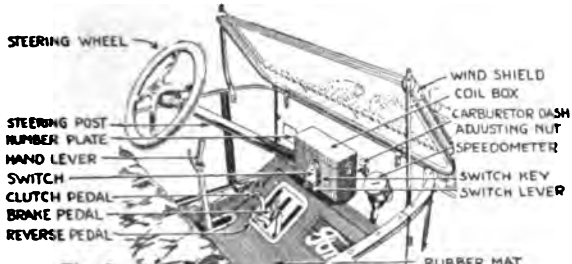

Fig. 3.

Place one foot on the foot brake, which is the pedal farthest to the right, so that you will always be prepared to stop and accidents may thus be prevented. Place the other foot on the clutch pedal, which is the farthest one to the left. Hold it in about mid position, that is, do not push this pedal all the way down, or let it come back all the way.

Now grasp the emergency brake lever handle with the left hand, having the palm of the hand turned towards the outside of the car and the thumb turned downward, so that the thumb can be used for disengaging the latch. This may seem awkward at first, but it is the way this lever is intended to be operated. Now, pull back on the handle,—then press latch with the thumb. It is easy to release the latch, if one pulls back on the lever first. **Now hold the steering wheel with both hands,** and push the clutch pedal forward slowly, until the car begins to move.

Gradually push the clutch pedal harder until you feel that there is no slipping in the low speed gear, and then speed up the engine so that the car is traveling at from 8 to 10 miles an hour. At the same time clutch pedal is pushed forward, push side hand lever forward as far as it will go, so that the clutch pedal may return to "high" when car is under way. The releasing of this clutch pedal engages the high speed clutch.

Let the clutch pedal come all the way back quickly, and your car will be in high gear. Practice will teach you how to make the change from low to high gear smoothly and easily, without jerk to the passeners or strain on the mechanism.

Reversing the Car.

Pull the emergency brake lever back just far enough to draw the clutch pedal forward and disengage the clutch, but do not pull the brake lever back far enough to engage the rear hub brakes.

Place one foot on the brake pedal, for use if necessary, and press gently on the middle, or reverse pedal. Do not attempt to drive backwards rapidly at first, for the steering is very apt to be confusing and it is not easy to drive backwards in a straight line. After the driver has become more experienced, he can reverse by holding out clutch with clutch pedal, and using low speed forward as a brake.

Stopping Car.

Partially close the throttle; release the high speed by pressing the clutch pedal forward into neutral; apply the foot brake slowly but firmly until the car comes to a dead stop.

Do not remove foot from the clutch pedal without first pulling the hand lever back to neutral position or the engine will stall.

To stop the engine, open the throttle a trifle to speed up the engine and then throw off the switch. The engine will then stop with the cylinders full of explosive gas, which will naturally make the next start easier.

Spark Control.

Left-hand lever under the steering wheel is the spark lever. Good operators drive with the spark lever advanced just as far as the engine will permit. But if the spark is advanced too far a dull knock will be heard in the engine, due to the fact that the explosion occurs before the piston has completed its compression stroke. The best results are obtained when the spark occurs just at the time that piston reaches its highest point of travel—the gas being then at its highest point of compression. The spark should only be retarded when the engine slows down on a heavy road or steep grade, but care should be exercised not to retard the spark too far, for when the spark is "late," instead of getting a powerful explosion, a slow burning of the gas, with excessive heat, will result. Learn to operate the spark as the occasion demands. The greatest economy in gasoline consumption is obtained by driving with the spark advanced sufficiently to obtain the maximum speed.

How Speed of Car is Controlled.

The different speeds required to meet road conditions are obtained by opening or closing the throttle. Practically all the running speeds needed for ordinary travel are obtained on high gear, and it is seldom necessary to use the low gear except to give the car momentum in starting. The speed of the car may be temporarily slackened in driving through crowded traffic, turning corners, etc., by "slipping the clutch," i. e., pressing the clutch pedal forward into neutral.

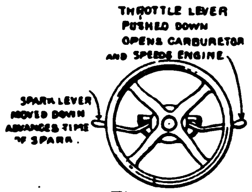

Fig. 4.

Starting Engine.

Before attempting to start the engine, see that the emergency hand brake lever is pulled back. This hand lever disengages the clutch and applies the brakes at the rear hubs, so that the car will not travel forward when cranking engine.

Be sure to retard the spark lever, that is, move the lever on the left hand side of the steering column, upward, or towards the front of the car, as far as it will go. (When speaking of the right or left hand side of the car, it is always considered that one is sitting in the driver's seat and facing forward).

The throttle lever, on the other side of the steering column, should be pulled downward about five or six notches, from the extreme forward, or closed position.

Now close the switch on the coil box, that is, move the switch key all the way over to the "mag." mark on the cover of the switch. If the switch key is moved over to the battery side, the engine cannot be started. The cars are not fitted with batteries, and this connection is only left on the switch, in case (at some future time) you should wish to equip your car with batteries for starting.

***Priming:** With present day grades of gasoline, it is usually necessary to prime the engine while it is being cranked. Priming shuts off some of the air, so a richer mixture of gasoline vapor is drawn into the carburetor.

This priming is done by pulling forward a small ring on the end of a wire that projects out through the radiator. This priming ring must be held out, at the same time that the engine is cranked.

Cranking engine: Grasp the starting handle firmly with the right hand, and push the starting crank in as far as it will go, feeling for the ratchets which the starting crank should engage. Hold the priming ring out with the left hand, and pull the starting crank up quickly.

The crank should be kept pushed in, while the handle is being pulled up. This requires a certain knack, that is soon acquired by practice. If not pushed in, the crank will slip out of the notches, and the sudden release may throw the driver off his balance.

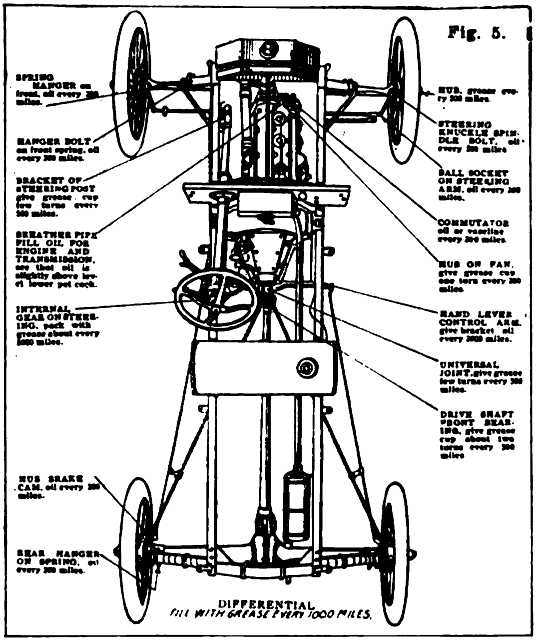
The crank should be pulled up sharply. Slow pulls are of no value, for, unless the engine is turned over quickly, the magneto will not give enough current to make a good spark (see page 490.)

Starting the Car.

Speed up the engine a little by opening or moving the throttle lever towards you, a couple of notches. Also, advance the spark to a normal running position, about five to seven notches, from the front of the quadrant.

CHART NO. 319—Operation and Control of Car. Starting Engine.

*See foot note bottom of page 578 for pages referring to difficult starting. Also page 798 and 799, this instructio



Lubrication.

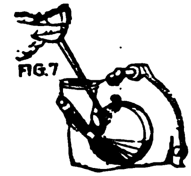
The plan view of the chassis, fig. 5, should be studied carefully, so that one will know how often the parts should receive attention and lubrication.

The oil cups can be supplied with the same kind of oil used in the engine, although a slightly heavier oil will not run away so rapidly and is better adapted to this use.

Oiling of the Commutator.

Oil is injected through the small cup on the top of the commutator shell. Engine oil is rather heavy for the oiling of the commutator and is apt to so insulate the roller from the contact points that starting may be difficult. This is especially true in winter, when the cold will so congeal a heavy oil that it will be almost impossible to obtain a good spark. "Three-in-one" oil is thin enough to be used in the commutator.

FIG. 7



Kind of Engine Oil to Use.

A light, high grade of gas engine cylinder oil is recommended. This light oil will reach into the closely fitted bearings of the engine more quickly and so less heat and friction will be developed. The oil should have sufficient body to prevent the heat and pressure in the cylinders, squeezing out the oil from between the cylinder walls and the pistons. It is expensive to use a cheap oil. Good oils save repairs to the engine, increase the mileage per gallon of gasoline, and do not form carbon nearly as rapidly as do inferior oils. In cold weather an oil that does not congeal easily at low temperatures must be used. Otherwise the clutch will drag, due to the oil acting as an adhesive. (see page 200 and 776.)

Among the oils that are recommended for the Ford engine, are Gargoyle Mobiloil "E," and White Star Extra Quality Oil, which is used at the Ford factory.

Graphite should never be used in either the engine or the transmission, as it is apt to short-circuit the magneto and thus cause expensive repairs. (see page 205.)

Draining Out the Oil.

The new car should have the oil drained out at the end of the first five hundred miles. This also applies to an overhauled engine, when the bearings have been refitted. The oil is drained out by removing the plug at the bottom of the crankcase, and cranking the engine. The front wheels should be about six inches higher than the rear wheels, so that the oil will drain to the rear of the crank case. *Kerosene can be poured into the breather pipe, to assist in washing out the old oil, and the engine cranked to splash this kerosene over all the parts. Use at least a gallon of fresh oil, when refilling the crankcase, and be sure to replace the plug in the bottom of the crankcase tightly. If this plug drops out, the engine bearings are almost sure to be ruined for lack of oil.

Greasing.

This includes the filling of the grease cups, the universal joints and the rear axle housing with grease. Cup grease, or grease containing graphite, can be used in the grease cups, and the rear axle should not be filled too full of grease. †About 1½ pounds of grease is enough for the rear axle gears. If thrust washers are not worn, ½ lb. more can be added. A larger amount of grease will run out of the ends of the axles and spread over the wheels and tires. (see page 782, for cause of leaking oil out wheel hubs).

†Vacuum Oil Co. state that the differential housing holds 4 lbs and correct level is 2½ lbs. of Mobilubricant.

The Universal joint is one of the most important parts to keep greased.

Oiling Engine and Transmission.

Oiling is most important and is taken care of by pouring oil through the breather pipe on the front end of the engine base. This pipe is covered by a metal cap, which can be easily pulled off, when oil is to be poured into the crank case. The lubrication of the engine is explained on page 197. See page 709, how to clean oil pipe.

When the engine is new: Pour in oil until it runs freely out of the upper petcock in the engine base (1, fig. 6). Be sure to close this petcock, for if it is left open, the action of the flywheel will splash all of the oil out through this petcock and the bearings will be ruined for lack of oil.

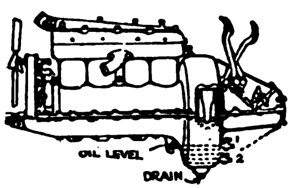


Fig. 6.

After the engine has been limbered up: The best results will be obtained by carrying the oil level about midway between the two petcocks—but under no circumstances should the oil level be allowed to get below the lower petcock.

****Testing the oil level:** If car is not fitted with an oil gauge as shown on page 782, fig. 35X, then open upper petcock. If oil does not drip out, open the lower petcock. If oil drips out, then there is enough oil for a short distance, but it is better to put more oil in if the car is to be driven a considerable distance. It is necessary at intervals to clean out these petcocks as they become clogged with dirt or sediment.

Oiling Other Parts.

This includes the filling of the different oil cups on the front axle system, the rear axle system, and the oiling of parts of the control system, which move but little. Oiling of these parts will tend to eliminate squeaks and prevent wear.

Mobilubricant; a handy grease gun containing the grease for Ford differentials and grease cups. (Vacuum Oil Co., Rochester, N. Y.)

CHART NO. 320—Lubrication.

*See page 201, about thoroughly draining the kerosene after cleaning.
**See pages 201, 197 and 776, "heavy oils," and page 709, how to clean oil pipe if clogged.

Steering Gear System.

***The steering reduction gears are placed at the top of the steering column, instead of at the bottom** (fig. 8 and 9), (as is customary on other cars). These gears increase the power, and the sensitiveness of the control over the front wheels of the car. If these gears were not used, a slight turn of the steering wheel would send the car into the ditch, while road obstructions, or bumps, would wrest the steering wheel out of the driver's control.

The lower part of steering column merely has an arm (A, fig. 9) which is connected to rod (B) extending to steering knuckle arm (SA).

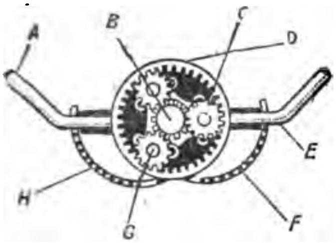

Fig. 8.

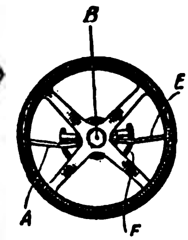

Fig. 8A.

A—Spark lever.
B—Drive pinion.
C—Pinion or gear.
D—Gear case.
E—Throttle lever.
F—Throttle quadrant.
G—Pinion pin.
H—Spark quadrant.

The steering wheel has a short shaft, on which a pinion (B) is mounted. This pinion is held in place by the cover and nut of the steering gear case. The steering rod proper, on the end is fitted with a flange, (triangle shape under gears) on which three studs project, which carry the three small gears. These gears mesh with the pinion (B) and also with an internal gear cut on the inside of the steering wheel case.

To obtain access to the gears: remove the small screw, which holds the gear case cover. Then unscrew the gear case cover, and the steering wheel and the cover can be removed together as a unit. It is not necessary to remove the lower part of the steering wheel from its shaft to obtain access to the steering gears.

There are two small **retaining keys** in the top of the steering column. Keep these keys snug, for if loose, considerable play will result.

Removing Steering Wheel.

Unscrew the nut on the top of the post, and drive the wheel off the shaft, using a block of wood and a hammer. Do not batter the threads of the shaft, or it will be difficult to replace the nut.

Tightening Steering Gear.

A loose steering gear will make steering difficult and cause wear of tires. To tighten, see that the nut which holds arm (A) at lower end of steering rod (R) fig. 9, is tight.

Ball and Socket Joints.

There is a ball on the end of arm (A), which fits into a socket (C), fig. 9-B. If not kept oiled play will develop.

There is also a ball on end of thrust rod (B) which connects steering arm (SA) fig. 9-A.

If the ball and socket becomes worn from lack of oil, it can be ground by rubbing over emery cloth, or filing as per fig. 93.

Spring ball sockets are now supplied by specialty manufacturers which take up wear automatically.

Bushings in Spindles.

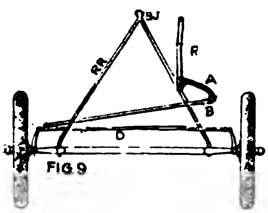
There are bushings in spindle arms (S) fig. 9-A, also fig. 11, chart 322. The "spindle arm bolt" works in the bushings. The bushings wear first and if worn should be replaced.

Removing bushings: Split expanding bushing removers are best for this purpose, or else bushing can be threaded and fitted with a bolt and driven out. The bushings are short and one at each end of spindle body.

New bushings should be pressed in with an arbor press or vise or carefully hammered in with a lead mallet, or wood between hammer and bushing.

After fitting, the bushings should be reamed out. Special reamers are made for this purpose—see page 792.

The bushings must fit snug so that the bolts will turn and not the bushings.



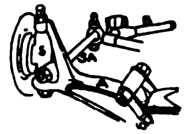


Fig. 9-A.

Fig. 9-B.

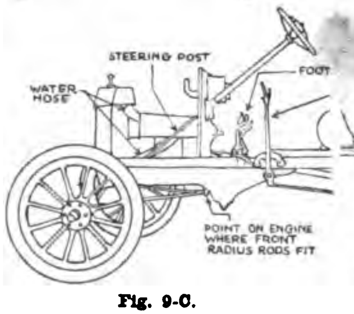

Fig. 9-C.

Fig. 93.

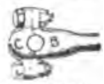

Fig. 9-E.

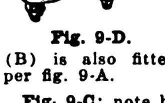

Fig. 9-D.

Fig. 9; the arm (A) is the only part connected to steering rod (B)—by means of ball and socket joint (fig. 9-B). Movement of (A) by steering rod (R) moves the front wheels. The other end of thrust rod (B) is also fitted with ball and socket joint as per fig. 9-A.

Fig. 9-C; note ball joint (BJ, fig. 9) fits in socket on engine base to support front radius rods.

Fig. 93; method of taking up wear on socket (C) which places the sockets closer together over the joint. The method is to emery the part down.

Fig. 9-D; shows the drag rod yoke (Y).

CHART 321—Steering Assembly.

The Ford steering device is the "planetary gear" type similar to fig. 37, page 693, but with the planetary gears at the top of steering column. The "cross" method of steering is used as explained on page 691.

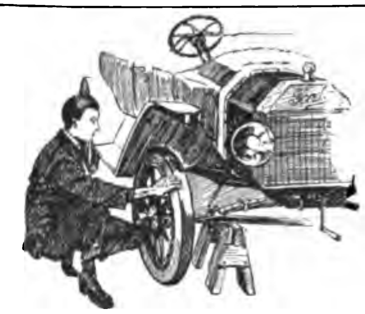

Fig. 10—Testing for play in front wheel.

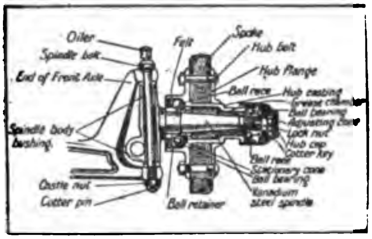

Construction of front wheel bearing.

Fig. 11—Names of parts of front wheel spindle assembly. Note that the bushings do not extend entirely through the spindle body; but only at each end.

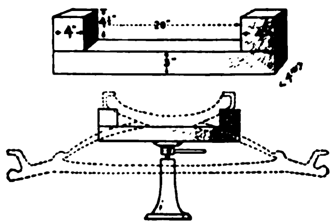

Fig 12—One method of jacking up front of car with a block of wood. The illustration shows method and dimensions. The block should be narrow enough to go between the front axle and steering connection that crosses about 4½ inches behind it.

**Front Wheels.

Removing the front wheels: Use special hub-cap wrench to remove hub-cap. Pull out the cotter pin, then take off castle nut, and lock washer. Unscrew the adjustable bearing cone. Then pull front wheel off.

The cones and castle nuts must be replaced on the spindles from which they were removed. There are left-hand threads on the left spindle and right hand threads on the other spindle. (Note—Turn top of nut towards front of car to tighten. This holds good for all wheel nuts.)

If the cones or cups are worn, they should be replaced with new parts. While slightly longer service can be obtained by turning the cones half-way around, so that the wear comes on the opposite side of the cone, this permits a certain amount of looseness and is not as good as the fitting of new parts.

If the balls are chipped, cracked, or pitted at all, they should be replaced by new ones. Chipped balls will break and ruin other parts of the bearings.

Testing the Wheels.

The front wheels should be jacked up every thousand miles or so, and tested for side play and smoothness of running. (see page 681.)

A sharp click; when running the front wheel, together with a momentary check in the motion of the wheel, indicates a broken ball, which should be immediately removed, before it causes trouble.

Adjustment.

The front wheels should be so adjusted that the wheels will come to rest—after spinning—with the tire valve at the lowest part of the wheel. Yet there should be no noticeable side play, when the spokes of the wheel are grasped with the hands and the wheel shaken as shown in figure 10.

Undue wear of the cones; may be caused by adjusting the cones so closely that the bearings bind; or to lack of lubrication. The hub-caps should be filled with a soft grease every few thousand miles.

Removing the Front Axle.

Jack up the front of the car, by supporting the frame on a couple of boxes, or by chains or ropes, or as per fig. 12. Remove both front wheels. Disconnect thrust rod (B) from arm (A) (fig. 9-A, chart 321). Disconnect the radius rod at the ball joint (per fig. 9 and 9-C, chart 321.) Remove the two spring shackle bolts at each end of the front spring.

To Disconnect the Front Radius Rod From Axle.

Remove the cotter pinned nuts. To remove the radius rod entirely—take the two nuts off the studs, which hold the ball cap, and remove the lower half of cap. (see chart 321, fig. 9, and 9-C.)

If the radius rod rattles; remove the lower half of the ball cap, and file some of the metal off the flat surfaces or rub down (as shown in fig. 93, chart 321.)

Straightening Front Axle.

In case front axle or parts are bent straighten them while cold. The application of heat will remove the effects of the heat treatment to which these parts have been subjected and will dangerously weaken them.

By bringing the point of contact of the tire and ground more nearly under the spindle body bolt, this makes steering easier and tends to prevent tire wear. (see fig. 13, and page 683).

Transposing Tires.

To use 30 by 3½ inch tires on the front wheels, a pair of rear wheels can be purchased and fitted in place of the original front wheels.

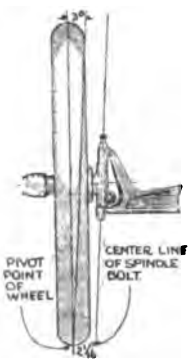

Fig. 13.

Springs.

Care of springs: If the springs seem stiff, use a screwdriver to pry the leaves apart and place some graphite grease, or heavy oil, between the leaves. (see page 622.)

Spring clips should be kept tight: If these clips are not kept tight, the strain will be put on the tie-bolt which passes through the center of the spring leaves and will break it. The tie-bolt is only intended for keeping the spring leaves from slipping out of position sideways. This is particularly true of the front spring, for if the front spring shifts sideways, it will endanger the steering of the car, and may cause an accident.

Making the Car Ride More Easily.

One or more leaves; can be removed from the rear spring of the runabout, to make the car ride more easily, as the same spring is used on both runabout and touring cars. The runabout does not carry so much weight. If one leaf is removed—take out the second. If several leaves are removed, take out alternate leaves, so as to maintain the general shape of the spring as nearly as possible.

For truck use; several leaves are sometimes added to increase stiffness of springs.

Alignment of Wheels.

Read on page 683, why proper alignment of wheels is necessary. The following will assist the reader in lining up the Ford wheels:

The front wheels are set at an angle of 3 degrees (1⁹⁄₁₆ inch*); i. e., the distance between the tops of the front wheels is 3 inches greater than between the bottoms. This is to obtain ease in steering. The wheels should not, however, toe in at the front, at least not more than ¼ inch, and lines drawn along the outside of the wheels when the latter are straight in a forward position should be parallel. A plumb line dropped through the spindle bolt should strike the ground just 2¹⁄₁₆ inches from the pivot point of the wheel, as seen in the accompanying diagram.

Adjustment of the front wheels can be made by turning the yoke at the left end of the drag rod, drawing the wheels into a parallel position. If inspection shows that the axle or the spindles are bent it will be necessary to have those parts straightened or replaced before correct alignment can be secured.

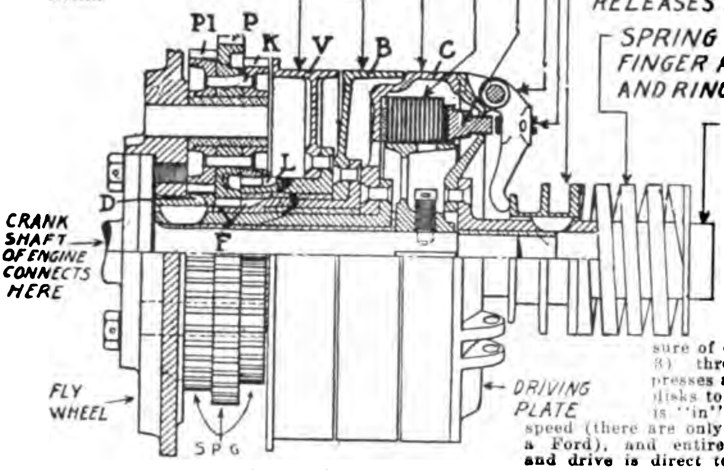
CHART NO. 322—Front Wheels and Axle. Alignment of Wheels.

*See page 115 for tables "Converting degrees into inches" and "hundredths into 64th." **Timken roller bearings now used on Sedan, Coupes and Trucks.

Low speed; gear D is driven member, keyed to the hub clutch drum C, which in turn is secured to driven shaft. By applying brake band to drum B, gear F is held stationary, pinion P rolls on it and a smaller pinion P1 causes gear D to turn slowly in the same direction as pinion carrier A.

For high speed or direct drive, the friction clutch locks the clutch drum C to engine crank shaft and the entire mechanism revolves as a unit.

For reverse; applying brake band to drum V, gear L is held stationary, pinion K rolls on it and pinion P1 turns gear D slowly in the reverse direction.



The clutch serves the same purpose as a cone or disk clutch as described on pages 39 and 41. The clutch on the Ford is made of steel disks as lettered. The pressure of clutch fingers (there are 3) through the ring which presses against disks, causes the disks to take hold. When clutch is "in" then the car is on high speed (there are only two speeds forward on a Ford), and entire transmission revolves and drive is direct to rear axle.

Principle of the Ford Transmission.

This transmission serves the same purpose as a sliding gear or selective type of transmission as explained on page 46.

It is mounted on a shaft (F) which has a flange projection at one end, which bolts to fly wheel and fly wheel is bolted to a flange on end of crank shaft.

The planetary gears are shown as marked, (PI, P, K, & S, P, G). These gears are mounted on studs projecting from fly wheel.

By means of bands, which are tightened around the drums, the rotation of these gears are governed as explained.

It is called a planetary transmission, from a fancied resemblance between the motion of the triple gears around the central shaft and the motion of the planets around the sun.

Principle: One can work out the action of these transmission gears most easily by taking a few coins, or washers. Place one coin in the center and the three around it touching the central coin.

When the central coin is revolved, it will be found that the three others are revolved in the opposite direction.

Now, if we place a second coin of smaller size over the central coin and three other coins of larger size over the three outside coins, we can show the principle of the low speed gears.

By revolving the small central coin it will tend to revolve the three larger outside coins. As these three coins are supposed to be connected to the three coins beneath them, these three lower coins will tend to revolve the lower central coin, but at a much lower rate of speed.

The reverse gearing operates on the same general principle, except that an additional pair of gears is used, which causes the direction of rotation to be reversed.

When in high gear, the gear ratio of the car is 3.63 to 1, because the bevel drive gear in the rear axle is so much larger than the pinion that the engine makes 3.63 revolutions for every turn of the rear wheels.

When the low gear is engaged the ratio in the transmission is 2.75 to 1. This is multiplied by the rear axle reduction; so the total gear ratio, when in low gear, is 2.75 times 3.63, equals 9.98, or practically 10 to 1.

In general, owing to frictional losses in the transmission, and other causes, it may be assumed that the car will travel about three times as fast in high gear as in low. But the car will have about twice as much power when low gear is used.

When reverse gear is used the ratio is 4 to 1. The ratio to the wheels is 4 times 3.63, or 14.52, or, say, about 15 to 1. But owing to the number of gears transmitting the power when reverse is used the actual available power in reverse is not as great as might be supposed. However, it is sometimes possible to use the reverse gear to pull the car out of a mudhole when even the low speed gear does not have sufficient power.

CHART NO. 323—Principle of the Transmission.

Fig. 15: Adjusting clutch fingers. Jack one rear wheel up, turn engine so clutch fingers come in convenient position, remove split-pin, give half a turn clockwise to the screw, and replace pin. Don't drop pins in transmission case. After long wear, new discs will be needed. It will be necessary to remove the transmission cover.

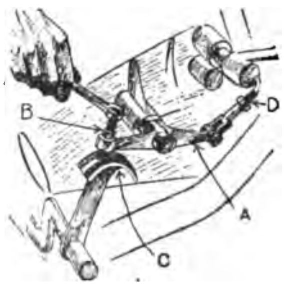


Fig. 15A: Tightening screw B to hold clutch in neutral position—see also fig. 18.

Clutch Control.

Is by the left pedal at the driver's feet. If the clutch pedal, when pushed forward into slow speed, has a tendency to stick and not to come back readily into high, tighten up the slow speed band as directed.

Should the machine have an inclination to creep forward when cranking, it indicates that the clutch lever screw (B), which bears on the clutch lever cam (C) has worn, and requires an extra turn to hold the clutch in neutral position.

When the clutch is released by pulling back the hand lever the pedal should move forward a distance of 1¾" in passing from high speed to neutral. See that the hub brake shoe and connections are in proper order so that the brake will act sufficiently to prevent the car creeping very far ahead. Also be sure the slow speed band does not bind on account of being adjusted too tight.

Clutch Slips or Drags.

Slipping clutch may be due to worn main bearings, allowing crankshaft to vibrate, or to use of heavy oil in engine.

When clutch drags: This may be due to heavy or old oil. This oil collects between the clutch plates, and does not allow them to separate freely from each other, as they should, when the clutch is disengaged. An oil that is too heavy for the clutch plates, is also too heavy for good use in the engine. Heavy oil will not penetrate into the closely fitted bearings, and if the oil does not get in, friction and rapid wear will result.

Heavy oils are sometimes used in Ford engines with the idea that the heavy oil will seal the gaps between worn pistons and cylinder walls, but the only effective remedy is to replace pistons and other worn parts as needed. **In winter oil should have a low cold test,** that is, the oil should not congeal easily. It it does, the engine will be very hard to start on account of the **dragging of the clutch and the bands on the transmission drums.**

Fig. 16: This clamp is used to hold transmission bands together while replacing the transmission cover. It is made of spring steel ⅛ in. wide and 5/32 in. thick, bent into the form of a U, having legs 3⅝ in. long and being 2 7/16 in. across. One of these is clamped over the lugs on the transmission bands before replacing the cover and removed after the cover is bolted on. (Motor World.)

Transmission Gears.

If teeth of triple gears are worn or chipped, to such an extent that they do not properly mesh, they will cause a growling or grinding noise; especially when low or reverse gears are used.

Transmission Bearings.

The transmission is supported at the rear end by a babbitt lined bearing at the universal ball cap. If this bearing is worn it will cause a knock in the transmission when the car is traveling over rough roads.

Worn bushings in the second speed and reverse drums, throws the transmission shaft out of line, hence the gears become worn and noisy. It is advisable to install new bushings as soon as worn and that before they cause gear teeth trouble, which means an ugly grinding noise.

A "chattering" noise in transmission means that new band linings are needed. The same remedy applies when car runs with a jerky movement.

To Remove Transmission.

Take the upper part of engine off the lower part of crankcase, as explained under "removing power plant," (chart 330). Next remove the transmission cover **(fig. 16), and crankcase cover.** Then the four cap screws that hold the fly wheel to crankshaft flange, using special Ford flywheel cap screw wrench No. 1929. The entire transmission may be then easily removed from the cylinder block assembly.

CHART NO. 324—Transmission and Clutch Pointers.

The width overall dimensions of Ford Touring, Runabout, Sedan, Coupe, Chassis and Truck Chassis is 5' 7½".
The overall length is 11' 2½" on all above except model T chassis, which is 10' 8" and truck chassis 12' 9".
The overall height on Runabout, Sedan and Coupe is 6' 9" and on Touring car 7'.
The smallest garage measurement for housing a Ford, and which will allow 2' 2¼" on sides and 2' 4¾" play at each end would be 10' wide, 16' long and 8' high. (See also, page 821.)

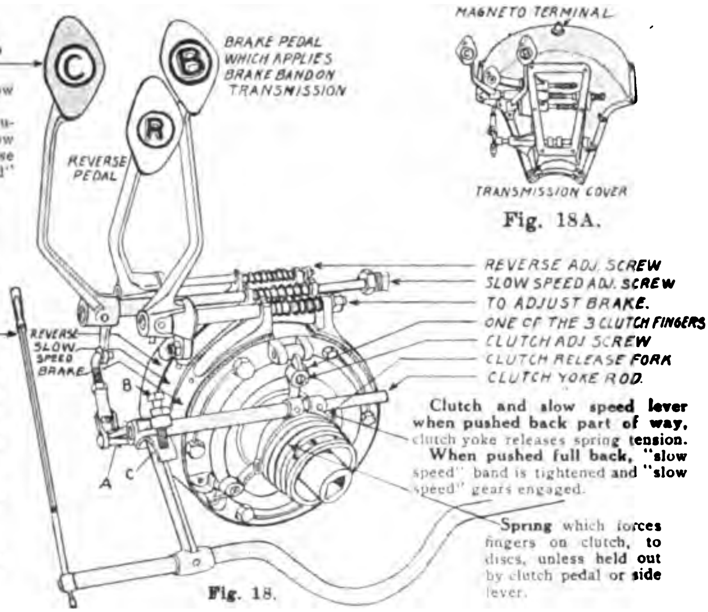

Fig. 18A.

CLUTCH AND SLOW SPEED FOOT PEDAL.

Full forward position, "low speed" band is tightened.
Half way forward, is neutral, when in this position throw band lever forward, release clutch pedal and "high speed" clutch is engaged.

Fig. 18: Connection of hand lever and foot pedals to transmission.

SIDE HAND LEVER

Center Vertical Position, holds clutch "out" by screw B, being on top of oval eccentric C, thereby forcing fork against spring, releasing tension against clutch discs.
Forward Position, as now illustrated, spring tension is released and on "high speed."
Back Position, spring tension is released and "brake" bands on hubs of rear wheels applied.

Clutch and slow speed lever when pushed back part of way, clutch yoke releases spring tension. When pushed full back, "slow speed" band is tightened and "slow speed" gears engaged.

Spring which forces fingers on clutch, to discs, unless held out by clutch pedal or side lever.

Fig. 18.

Causes and Symptoms of Worn Transmission Band Linings.

Cause: When starting the car, the driver should press the pedal forward until the low speed begins to engage. Then the pedal should be pressed more slowly until there is no slipping of the band on the drum. When using the low speed gear on long, steep hills many drivers unconsciously relax the pressure on the pedal, so that the drums slip and wear the bands. Hold the pedals in firmly when the gears have once been engaged.

Another cause of rapid wear of the bands is the habit of some drivers of racing the engine at high speeds before attempting to engage the transmission bands. The best driver is the one who can use the gears and not speed up the engine any faster than will just avoid stalling. If the engine is not raced too fast there will not be so much difference between the speed of the transmission bands and the speed of the drums. Then there will be less wear on the band linings and less strain on all parts of the car.

When the transmission band linings have become hard and glazed they will not grip the drums until the pedals have been pushed very hard and all the oil has been squeezed from between the bands and the drums. Then the bands take hold with a series of jerks and this causes a chattering and severe strains on both the transmission and the rear axle assembly.

Other evidences of worn transmision bands are; (1) the failure of the foot brake to hold in spite of all the adjustment that can be made through the cover on the top of the transmission case, without causing the bands to drag. (2) or **if the low speed and reverse gears slip when the pedals are pushed,** and the engine races, while the car does not travel as fast as it should.

On an average, the brake linings should give good service for about six months; with good driving, from ten months to a year of service may be had, counting on from five to ten thousand miles driving as a year of service. (Fordowner.)

By driving on throttle, as much as possible instead of using the clutch so often, the bands will wear longer.

To Tighten Brake and Reverse Bands.

*Remove the transmission case cover and turn the adjusting nuts on the shafts to the right. (fig. 18A.)

The bands should not drag on the drums when disengaged, as they have a tendency to exert a brake effect, and overheat the engine. The foot brake should be adjusted however, so that a sudden pressure will stop the car immediately, or slide the rear wheels in emergency cases.

To Tighten Slow Speed Band.

Loosen the lock nut at the right side of the transmission cover, and turn the adjusting screw (see fig. 18) to the right.

Size of Band Linings.

See page 770. The dia. of brake, slow speed and reverse drum is 7½"x1³⁄₁₆" wide.

*See page 778, how to remove transmision cover.

CHART NO. 325—Transmission Parts and Location.

Removing Transmission Cover.

(1) Remove magneto wire.

(2) Loosen the nuts on the studs of the clamps which hold the exhaust manifold in place.

(3) Pull manifold and exhaust pipe out of muffler and remove them from car—save the gaskets.

(4) Remove the ⅝ inch bolts holding on the transmission cover. (Use L-handle wrench No. 2322 for keeping nuts from turning, while the bolts are turned from below, by using T-wrench No. 2320.)

(5) Loosen and remove the two bolts which hold the universal ball cap to the transmission cover.

(6) Loosen lock nut on low speed screw and loosen low speed adjustment.

(7) Push emergency brake lever forward.

If cover is hard to remove, then loosen nuts on reverse and brake adjustment nut as far as they will go and remove the slow speed adjusting screw.

Removing Bands.

Now cover can be pulled off, and then the bands.

Place band nearest the flywheel over the first of the triple gears. Turn the band around so that opening faces downward. Band can then be removed by lifting up.

If three sets of triple gears are so placed that one set is about ten degrees to the right of center at top, the operation is considerably simplified. Each band is removed in the same way. It is important to shove each band forward on to the triple gears—as at this point there is only sufficient clearance in the crank case to allow the ears of the transmission bands to be turned down.

Relining Bands.

Instructions for relining brake bands are given on pages 688 to 690.

Never use linings containing metallic reinforcements for the transmission bands. Special Ford linings should be used. Particles of wire, worn from ordinary band linings, are apt to cut through the insulation of the magneto, which is in the same compartment as the transmission. A short circuited magneto necessitates pulling the engine out of the car for repairing.

At the Ford branches or agencies, transmission bands can be exchanged for 40 cents each. As the cost of the linings and rivets is about 30 cents, it usually pays to exchange the bands.

Use soft brass rivets: When relining the transmission bands use soft brass rivets. If iron rivets are used, particles of iron, worn from the rivets, will be attracted to the magneto, and will tend to cause short circuits.

Iron rivets are so hard that they will cut and score the soft iron brake drums, thus making them liable to break.

To Install Bands.

Simply follow the reverse of the procedure of removing the bands. When the three bands are placed in an upright position on the drums, the ease of placing transmission cover on can be facilitated by passing a cord around the ears of the three bands, holding them in the center—the pedal shafts can then be made to rest in the notches in the band ears.

The clutch release ring should also be placed in the rear groove of the clutch shaft.

Replacing Transmission Cover.

First—tie the lugs of the three bands together tight, with a piece of wire or cord—or construct a band holder as shown in fig. 16, page 776.

Second; make sure that all the gaskets are in place and that none of them are defective. Broken gaskets will allow oil to escape, when the engine is running. The oil is splashed around in the transmission case by the flywheel and transmission drums.

Third; loosen the nuts on the brake and slow speed studs as far as they will go, without danger of falling off.

Fourth; compress the springs on these operating studs. This will make it much easier to replace the transmission cover.

Fifth; replace cover and all the bolts, and tighten them securely. It is not usually necessary to fit those around the sides with cotter pins. However, the bolts holding the universal ball cap must endure greater strains, so they should be fitted with cotter pins.

Remove the cord or wire, which were used to hold the bands in place while the cover was being installed.

Adjusting Bands.

Adjust bands so that the pedals can be pushed down to within a couple of inches of the floor boards, before the bands grip tightly. After running a couple of hundred miles, adjust the bands again, use double end wrench, No. 1917.

Explanation of Transmission.

Illustration on next page explains the relation of one part of the transmission to the other—as does also the illustration on page 775.

Figures 19 to 19G illustrate the parts of the transmission separated, but in their respective order to be assembled.

Clutch; note the 12 small clutch disks or thrust plates (20D) and the 13 large disks (20E), are placed together alternately (see 19B).

The projection on small plates fit slots of disk-drum (19C). The latter being rigidly fastened to transmission shaft (TS), whereas the slots in large plates fit in projections (LPP) of illustration 20A. The disk-drum (19C) is fastened to transmission shaft by set-screw (S). The pressure of the "clutch push ring" (19A) due to the tension of "clutch spring" (19) against "clutch fingers," causes the large and small disks to grasp. The adjustment of clutch fingers is made by screws (AS).

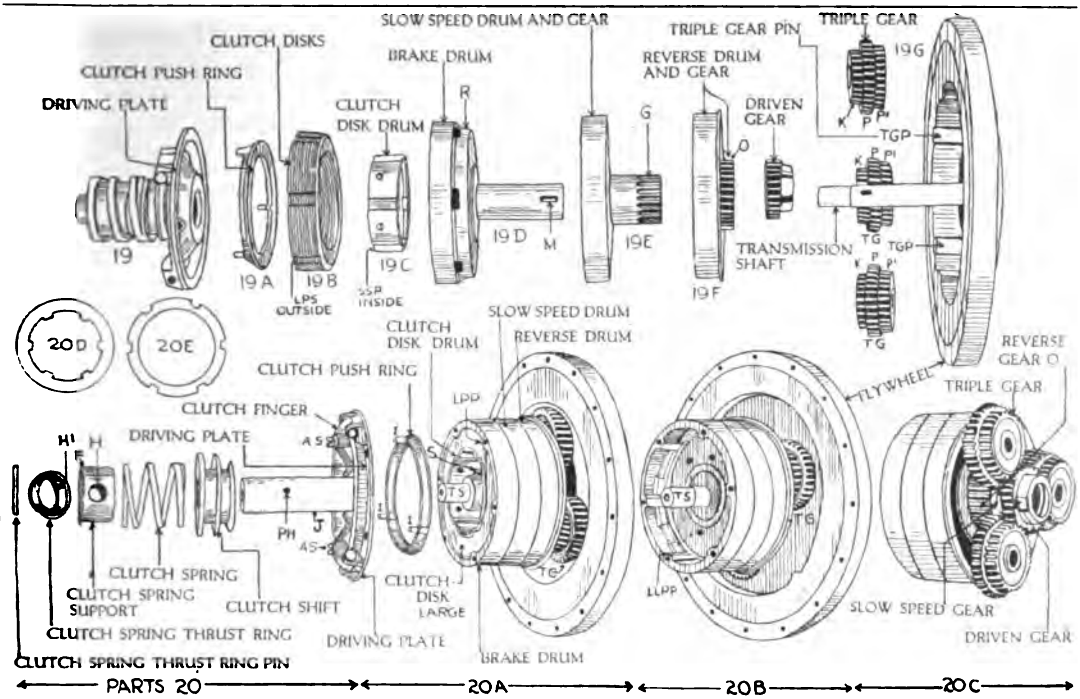
Transmission shaft (TS) and small plates (20D) run free in brake drum, when clutch is disengaged, in other words the small plates revolve with flywheel.

Slow speed drum (19E) fits over the part (R) of brake drum (19D). Driven gear is fastened to hollow shaft (M) of brake drum (19D) by means of two Woodruff keys.

Triple gears (TG); (K) are the reverse gears, (P) the slow speed gears, and (P1) the driving gears. These gears are fastened rigidly together in groups of 3 and are called triple gears on that account. There are 3 groups and they revolve freely on pins (TGP) of fly wheel. K—meshes with gear on reverse drum (19F); P—with gear (G) on hollow shaft of slow speed drum 19E; P1—meshes with driven gear, and is keyed to hollow shaft (M) on brake drum 19D, which projects past gear G.

The action can now be studied by referring to this illustration and page 775.

CHART NO. 326—Removing and Replacing Transmission Cover and Bands.



How to Assemble the Transmission.

First—assemble the group of parts as shown in 20C as follows; place the brake drum (19D) so that hub is in a vertical position—place the slow **speed drum (19E), with gear (G) up, over the shaft** (M) of brake drum. The slow speed drum will then fit over (R).

Next, place the reverse drum (19F) over the hollow shaft of (19E) so that the reverse gear (O) on drum surrounds the slow speed gear (G).

Then fit two Woodruff keys in the shaft of slow speed drum at (M) and place the "driven gear" (with teeth down) so that they will then come next to the slow speed gear (G).

Triple gears (TG) (all 3 groups); should now be meshed with the driven gear, according to the punch marks on the teeth—the reverse gear or smallest of the triple gear assembly being down.

When the triple gears are properly meshed, tie them in place with a string or cord passed around the outside of the three triple gears.

Second—assemble parts to fly wheel per 20B; place fly wheel on bench with face down, and shaft vertical.

Turn the group (20C) up side down, and place over the transmission shaft—so that the three triple gear pins (TGP) on fly wheel will pass through the triple gears.

This will now leave the brake drum on top, as shown in 20B, ready to take clutch disks (19B).

Fitting the Clutch.

Third—fit the clutch disk drum key in the transmission shaft; press the clutch disk drum (19C) over the transmission shaft (TS) (20B), and put set screw (S) in place to hold the drum.

Put a large clutch disk (20E) over the clutch drum, then a small clutch disk (20D) alternating with large and small disks until the 12 small and 13 large disks are in place—a large clutch disk—or "thrust plate" as it is termed, will then be on top as shown at (20A). Don't put a small disk on top.

Now place the "clutch push ring" (19A) over the clutch drum, so it will be on top of the disks—with the pins (1) up.

Fourth—group 20; next bolt the "driving plate" in such a manner that the adjusting screws of the three "clutch fingers" will press against the "clutch push ring pins" (1).

Fifth—it is now advisable to test by moving the clutch disks, and see if they will move freely by hand. If properly assembled, the fly wheel will revolve freely while holding any of the drums stationary.

Sixth—assemble the clutch spring parts. Place "clutch shift" (parts 20), over the driving plate hub (J), so that the small end rests on the clutch fingers. The clutch spring support is then slipped into the spring so that the flange (F) will rest on the upper coil of the spring, then insert "clutch spring thrust ring"* and press same into place. Insert the pin in the driving plate hub at PH, through the hole (H[1]) in the side of the thrust ring. This part of the work requires some "knack" but is simplified considerably by using a compressor similar to that shown on page 819. The large holes (H) in clutch spring support facilitate the insertion of the pin.

Another easy method of compressing the clutch spring, so that the pin can be inserted, is to loosen the tension of the three clutch finger adjusting screws (AS).

When the clutch is tightened up again, the spring should be compressed to within a space of 2 or 2 1/16" to make sure the clutch spring does not slip.

The adjusting screws (AS) should be adjusted so that there is even tension all around the clutch disks. These screws are now provided with a slot and it is necessary to turn them at least 1 revolution so that the slot comes in line with the cotter pin holes, then insert the cotter pins.

CHART NO. 326A—Assembly of the Transmission and Clutch.

*On the new cars "clutch spring thrust ring" is not used, its function being incorporated in "clutch spring support" the inner end of which is contracted and has 4 small lugs for the reception of the "thrust ring pin."

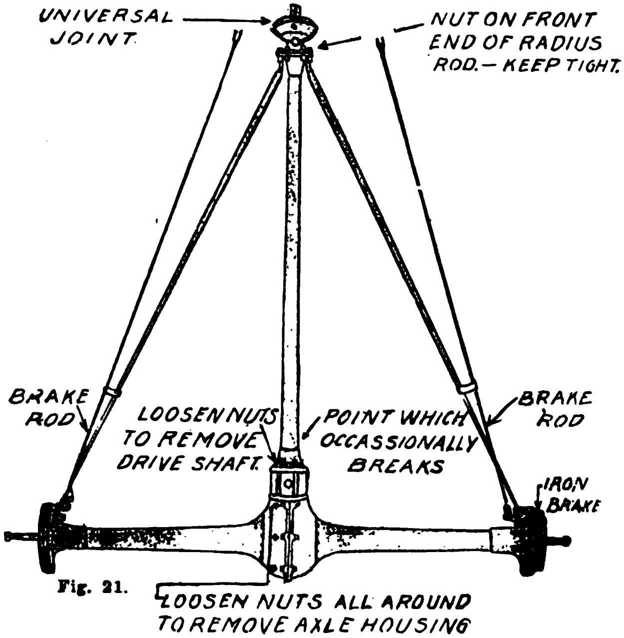


Fig. 21.

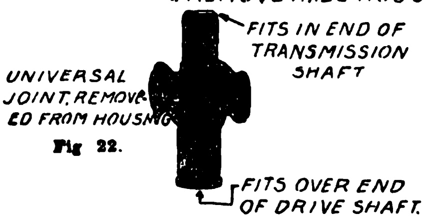

Fig 22.

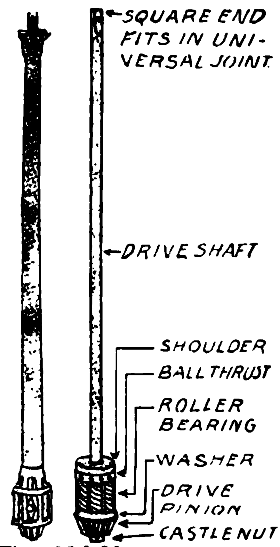

Figs. 25 & 26.

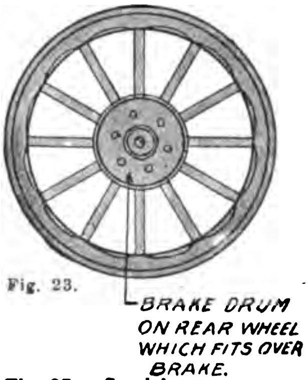

Fig. 23.

Fig. 27 — Special gears for trucks and racing. (see page 781; "Gear Ratios.")

Rear Axle and Parts.

The axle housing is made in two parts, (fig. 24.) The later types of rear axle housings are much stronger than those made in earlier years.

Drive shaft and housing (fig. 25.) The housing or tubing, encloses the drive shaft and also takes the torque or twist off the rear axle, when the car is being started or stopped. This sometimes causes the tube to break, near the rear axle.

Drive shaft and its bearings (fig. 26.) There is a roller bearing to support the shaft and pinion, and a ball thrust bearing above the roller bearing to take the thrust of the pinion against the drive gear.

The entire rear axle and drive shaft, per fig. 24—must be removed when repairs are to be made to differential, drive gears, or new axle shaft installed.

To Remove Rear Axle.

Jack up car and remove rear wheels (see chart 328). Take out 4 bolts connecting unniversal bolt cap to transmission case. Then disconnect brake rods. Remove nuts holding spring perches to rear axle housing flanges. Raise frame at rear and remove entire axle. (see fig. 21.)

Disconnecting Universal Joint.

The two plugs from top and bottom of ball casting must be removed, then turn shaft until pin comes opposite hole. Drive out pin and force joint away from shaft. (see fig. 30.)

To Disassemble Rear Axle.

See fig. 21 and 24. Disconnect universal joint first, then radius rods, then loosen nuts on studs holding drive shaft to rear axle (fig. 21.) Next, remove the nuts holding the axle housing together over differential as per fig. 24. The axle housing, in two parts is then removed from axle shafts.

To Remove Axle Shafts.

Follow the plan in preceding paragraph, and as per fig. 21 and 24. Take the inner part of differential casing apart and draw axle shaft through casing at the center.

When replacing axle shaft be sure rear wheels are firmly wedged on at outer end and key in proper position. With a new car the hub caps should be removed and lock nut tightened, in fact it is essential that rear wheels be kept tight.

If rear axle or wheel is sprung by skidding or striking a curb, or if axle shaft is bent—replace at once.

Removing Drive Pinion.

The pinion end of the drive shaft, to which the pinion is attached, is tapered to fit the pinion tapered hole which is keyed onto the shaft, and then additionally secured by a cotter-pinned "castellated" nut. Remove the castle nut, and drive the pinion off. (fig. 25 and 26.)

No adjustment is provided. Fit new parts if worn.

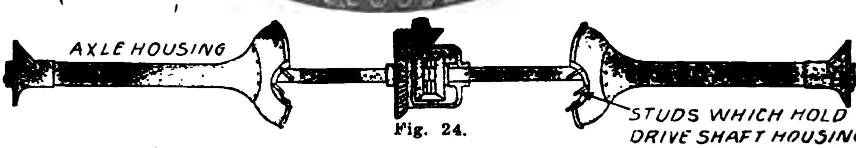

Fig. 24.

CHART NO. 327—Rear Axle. Special Gear Ratios.

Note—Rear axle is a semi-floating type and it is necessary to remove entire axle assembly and then the housing (as per fig. 24), to reach differential and drive gears. (see also page 669.)

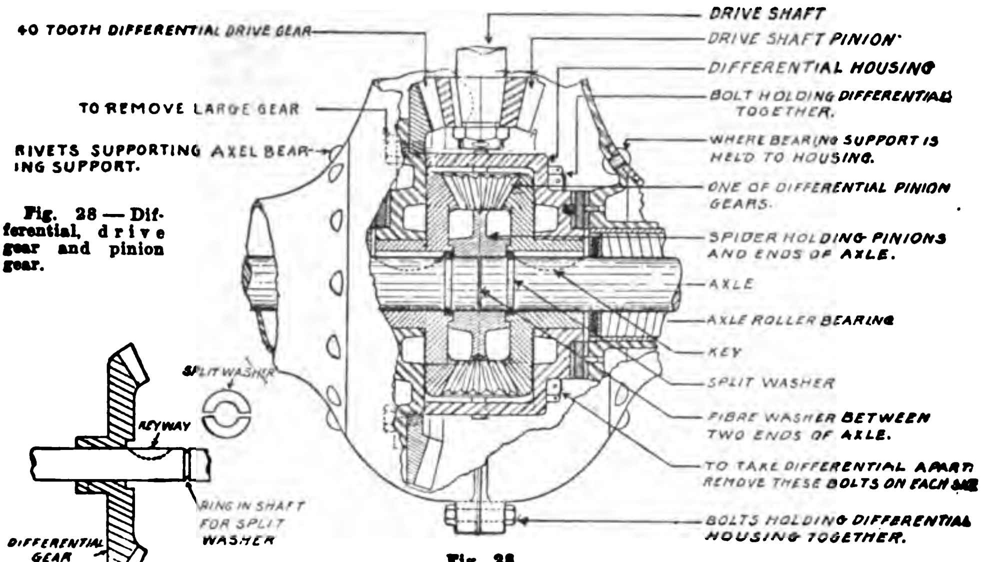

Fig. 28 — Differential, drive gear and pinion gear.

Fig. 28.

The Differential.

The principle of a differential is explained on page 85. There is no adjustment on the Ford differential between the pinion and drive gear. New parts are usually fitted.

Removing differential gears: The gears are keyed on to the axle shafts and held in position by a ring or split washer, which is in two halves and fits in a groove in the rear axle shaft. (see fig. 96, page 782.)

Force them down on the shaft, away from the end to which they are secured, drive out the two halves of ring in the grooves in shaft with screw driver or chisel, then the gears can be forced off the end of the shafts.

Rear Wheels.

Are fitted with pressed steel brake drums to which the emergency or hand brake operates. See fig. 29, 28 and 21.

To remove rear wheels take off hub cap, remove cotter pin, unscrew nut and with a wheel puller remove wheel from tapered shaft to which it is locked with a key.

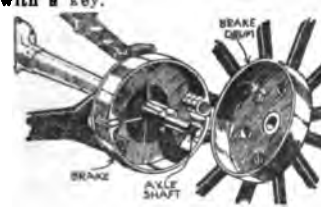

Fig. 29.

Brakes.

Fig. 29. The cast iron brake shoes will wear if used very much. This brake is usually used for holding car when at rest on an incline and not for slowing down car.

Brake shoes, lined with asbestos fabric can be obtained from accessory dealers and will last longer than plain cast iron shoes.

To replace these brake shoes, (1) remove the rear wheels; (2) unscrew nut and bolt on which the brake shoes are pivoted to the axle housing. Brake shoes can now be pulled off.

Put springs in place on new brake shoes; then place open ends of brake shoes over the cams, and swing brake shoes into place.

Replace wheels, and tighten the axle shaft nuts securely, before putting the cotter pins in place.

Equalize the rear hub brakes, by removing cotter pins and pulling out the clevis pins (see fig. 88, chart 829) and then turning the clevises on the brake connecting rods until the two brakes grip equally. Be sure that the clevises catch enough threads on the brake rods to give strength.

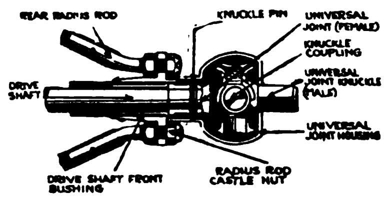

Fig. 30.

Universal Joint and Shaft Bushing.

Fig. 30. The universal joint and the driving shaft front bushing. When this bushing becomes worn, (which will take a long time, if the grease cup is turned regularly) it will be necessary to have the new bushing forced in at a Ford repair shop and then reamed to fit the axle shaft. This is a machinists job.

A Special Transmission.

A two speed rear axle is made for Fords by specialty concerns, which is useful for one-ton truck work. This gives 4 speeds. The third speed can be used on steep hills without holding foot on low speed pedal. (Woodword Truck Att. Co., Los Angeles, Calf.)

*Gear Ratios.

The standard ratio is 3⅔₁₁ to 1. Changes can be made by purchasing the gears, fig. 27, from Detroit Radiator Specialty Co., Detroit Michigan. It is necessary to change both drive gear and pinion.

For racing use 2⅘ to 1; Fast roadsters use 2¾ to 1; General use for level country use 3 to 1; General use; average country use 3⅔₁₁ to 1; Trucks, use 4 to 1.

For racing on dirt tracks where a quick pick up is required, the 3 to 1 is recommended. The 2¾ to 1 and 3 to 1 are interchangeable. The number of teeth are as follows for various ratios:

2¾	to 1;	gear 36 teeth,	pinion 13
3	to 1;	gear 39 teeth,	pinion 13.
3⅔₁₁	to 1;	gear 40 teeth,	pinion 11.
4	to 1;	gear 40 teeth,	pinion 10.

Average speeds: 2¾ to 1; 60 to 65 m. p. h.; 3 to 1, 50 to 60 m. p. h.; 4 to 1, varies according to weight; average 25 to 35 m. p. h.

CHART NO. 328—Removing Rear Axle Assembly and Parts. Replacing Brake Shoes. Univers Joint. Gear Ratios.

See page 825 for Ford truck. *The Krom-nik Gear Co., 801 Grant Park Bldg., Chicago, supply differential ge 4.2 to 1 ratio for hilly country and 3 to 1 for racing purposes.

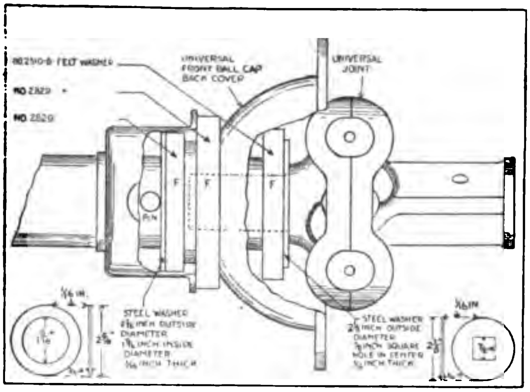

Fig. 31—Remedying excess of oil leakage out of wheel bearings: The oil from the transmission works down the drive shaft, through the universal joint through the differential out the axle ends, causing an excess of oil on the brakes.

To overcome this, place a felt washer at F. (Note the Ford stock numbers on these felt washers.) Then place steel washers (see illustration for size) as shown in illustration.

To put these washers in place, remove rear axle and rear half of universal joint, then remove front universal cover ball cap cover. Put felt and metal washer on as shown by placing same over transmission shaft. Then put No. 2829 washer on after cover is removed. Note the pin which will hold the washers in place. The washer 2510B and steel washer are easily applied when universal joint is apart. Reassemble carefully.

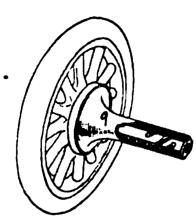

Fig. 32—shows another simple means of remedying this difficulty if too much lubricant is carried in the differential, for a time at least. Cut from a thick pad of felt a strip that is long enough to be wrapped around the axle shaft three or four times. This felt should be thick enough so as to fit snugly between the shaft and the housing and wrap it around the shaft as shown.

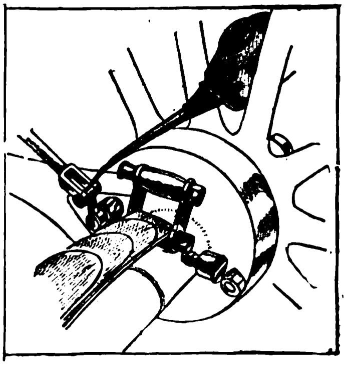

Fig. 34—When a Ford axle shaft becomes bent at the hub it may quickly be straightened by the device shown. An old Ford hub is attached to a heavy piece of pipe several feet long and this is slipped on the bent axle end while the engine is turned over slowly with high gear engaged. The end of the pipe will move in a circle due to the bend and by pulling pipe back to axle center the axle can be straightened.

Fig. 33—Oiling the emergency brake rod clevis pin.

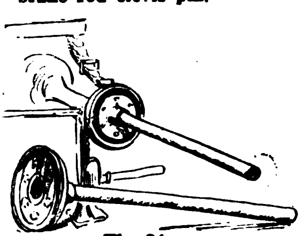

Fig. 34.

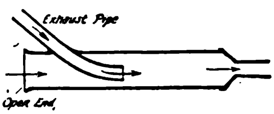

Fig. 35: To increase efficiency of exhaust for racing; a method, is to run pipes, with gradual bends from each exhaust port to an expansion chamber. Pipe leading from expansion chamber to rear should have a gradual increasing diameter to permit gases to expand as they cool.

Grease Leaks from Rear Axle.

Grease leaks from rear axle: Due to too much grease. One and a half pounds of grease is plenty, but a small amount should be added every thousand miles.

Another reason for the leakage is, that in this construction Hyatt roller bearings are used, which tend to permit leakage of fluid or semi-fluid lubricants. The crown wheel (or main differential gear) takes up too great a quantity and distributes it to the shafts. The centrifugal action of these shafts carries the lubricant to the outer end and if felt washers are not in first class condition, the grease works out to the brake drums.

Worn thrust washers allow axle shafts and differential to shift from side to side and pump grease out. This usually causes the grease to appear around the left wheel first, as that wheel is nearer the drive gear.

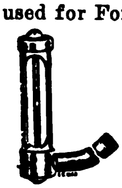
Worn thrust washers will cause the gears to grind. The noise will change as the car turns corners to right or left, and the weight of car is shifted from side to side.

Worn thrust washers require that the rear axle be removed from the car and taken apart, before new washers can be inserted. Ball bearing thrust washers are now made for Ford rear axles, and are claimed to wear longer. They should give less friction, and should therefore be useful for speedsters and racing.

The felt washers become worn and hard with use. They can be replaced—after removing the wheels—without taking the axle system off the car.

Two felt washers should be pushed on the axle shaft near the roller bearing next to the differential. A third felt washer should be placed near the outside end of the axle shaft, just inside of the outer roller bearing. These felt washers are cheap, and easily replaced, and, if only one pound of grease is used, will usually cure the rear axle grease leakage.

If light grease or oil is used it will leak out rapidly. If the grease is too stiff and heavy, the gears will simply cut a groove through the grease and the bearings will not be lubricated. Mobilubricant is often used for Ford rear axles, also Kaoga No. 2.



Oil gauge for Ford engine.

Fig. 35X: A glass gauge oil level indicator when screwed into the engine crank case will indicate the amount of oil at a glance. It is advisable to place a stop cock between gauge and crank case and keep it closed; only open when testing—to prevent loss of oil if gauge breaks.

Fig. 96. — Ford differential gears can be removed from the shafts by placing an old starting-crank ratchet in the face of the gear and driving it with a hammer till the gear is below the half-moon key. The key is then removed and the gear driven off.

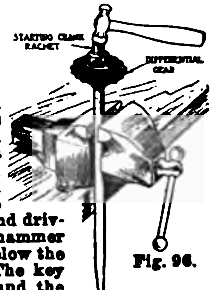


Fig. 96.

CHART NO. 329—Remedying Excess Oil Leakage out Rear Wheel Bearings. Axle Straightening.

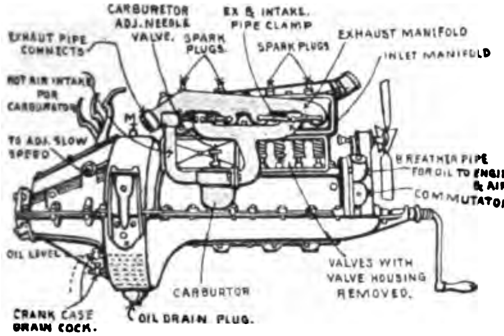

Fig. 36—**Right** side of Ford model T unit power plant. Showing inlet and exhaust manifold and valves.

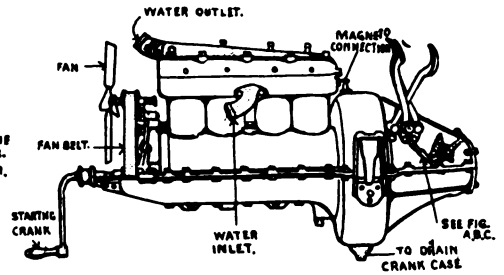

Fig. 37—**Left** side. Showing cooling water inlet and outlet. Note cylinders are "en-bloc," a typical unit power plant.

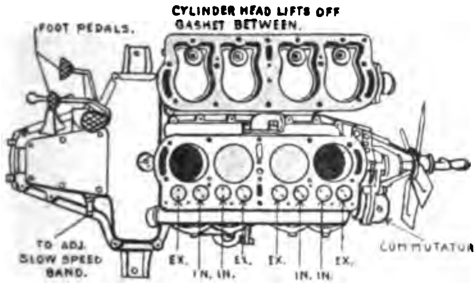

Fig. 38—**Top view.** Cylinder head removed showing cylinder bores, pistons and heads of valves in their seat. Note which are exhaust and which are inlet valves.

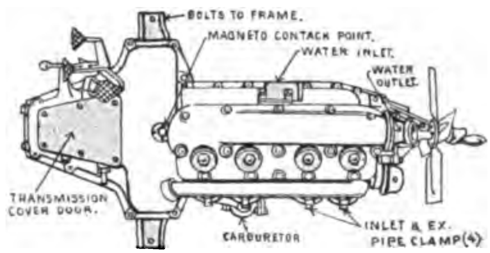

Fig. 39—**The cylinder head is removed by taking** off 15, 7/16x2 9/16 inch cap screws on top of cylinder. Underneath the head there is a gasket.

The Power Plant.

Engine, 4 cylinder, L head type with mechanically operated valves on the side. Bore 3¾ inches; stroke 4 inches. 22½ h. p. Cylinders are "en-bloc" type. Power plant is "unit type" because engine and transmission are combined so as to form practically one unit.

The cooling is by means of thermo syphon circulation as described on page 186 (figs. 1 and 2.)

Ignition; source of electric supply is an inductor type of magneto (described on pages 803, 805 and 265,) one part being attached to fly wheel and other part stationary. The current is carried to a commutator, thence to four high tension coils thence to spark plugs.

Carburetion; the Holley model G, and sometimes Kingston model Y carburetor is used as described on pages 798, 799 and 160.

Transmission; of the planetary type. It gives two speeds forward and one reverse. When driving on high speed the drive is direct and entire transmission revolves with drive shaft. When running on low speed the gears inside of low speed part of transmission are in action. The same when reversing.

The transmission is attached to the end of crank shaft (see charts No. 331, and 323,) and enclosed in a housing which covers transmission, fly wheel and magneto.

Gasoline feed system is gravity, see page 164.

Lubrication; gravity and splash. The fly wheel in revolving, picks up the oil and throws it by centrifugal force into the catch basin; from where it is led by ⅜ inch copper piping to the timing gears and then to the oil splash trough under the front cylinder. (see pages 772 and 197).

Location of Valves.

Location of valves: Front valve to the left of fan, (fig. 38), is No. 1 cylinder exhaust; then No. 1, inlet; then No. 2, inlet, No. 2, exhaust; No. 3 exhaust is next, then No. 3 inlet; No. 4 inlet and then No. 4 exhaust. Note the exhaust valves are next to the water jackets and nearest to the port openings where the cooling action is most effective.

*Removing the Power Plant.

(1) Remove hood;

(2) Drain the radiator;

(3) Loosen bolts holding top hose connection; (see fig. 53, chart 335-A.)

(4) Loosen bolts holding side hose connection to cylinder block;

(5) Loosen radiator-to-dash stay rod;

(6) Remove nuts and washers from the two bolts holding the radiator to the chassis;

(7) Remove radiator; (see page 789);

(8) Loosen cap screw holding commutator. Place commutator and wires to one side;

(9) Remove spark plug, and magneto wires;

(10) Remove spark plugs;

(11) Remove cylinder head. (Makes engine lighter and easier to lift);

(12) Remove 4 bolts holding universal ball cover;

(13) Turn off gasoline and disconnect feed pipe from carburetor;

(14) Remove nuts from studs holding inlet and exhaust manifolds;

(15) Take off the inlet manifold, with carburetor attached;

(16) Take off exhaust manifold, with exhaust pipe complete;

(17) Remove the two bolts holding the pans to each side of the base and knock the pans down out of the way;

(18) Loosen nuts holding arm (A) fig. 9, page 773) on lower end of steering post;

(19) Remove three bolts holding steering column to chassis;

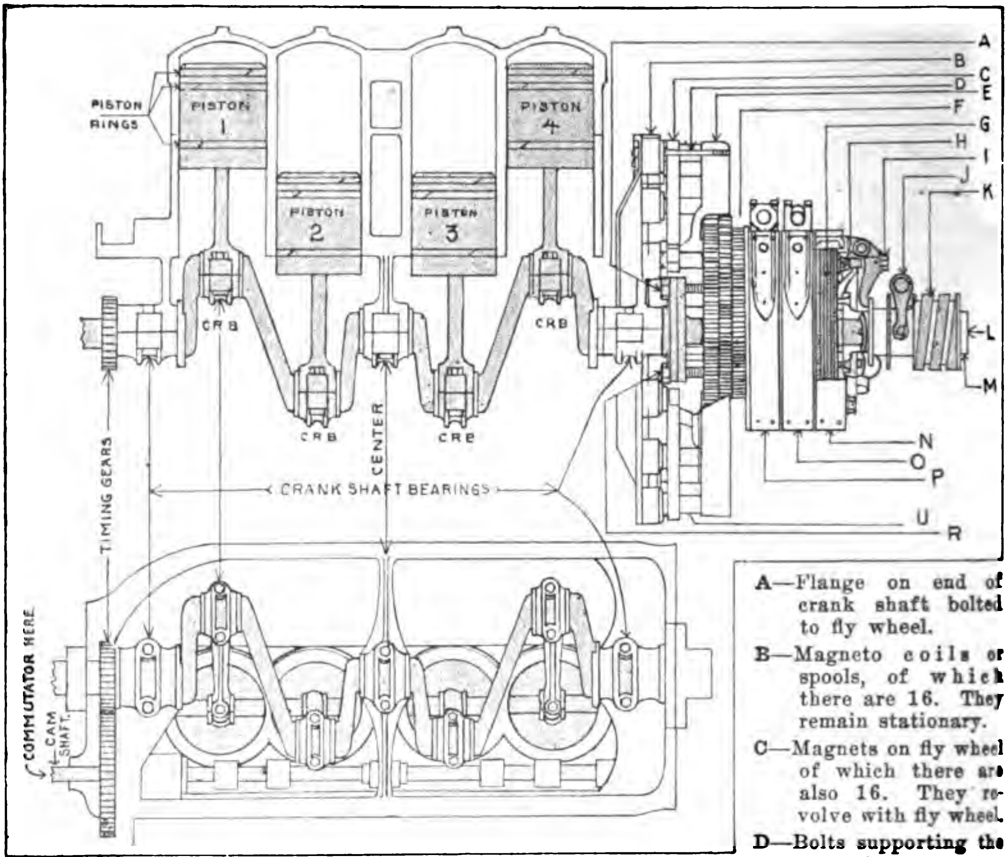
(20) Loosen dashboard, and pull dash and steering column up out of way. (Note: Not necessary to loosen dash or steering on 1917 cars);

(21) Remove nuts from front radius rod ball joint (see fig. 9-C, page 773);

(22) Loosen and remove bolts holding engine to frame, and then power plant can be lifted out.

CHART NO. 330—The Power Plant. Removing Power Plant. See also page 806.

See Insert No. 2, which is a half-tone engraving of the engine. ***On 1917 and later cars, the engine can be removed without removing the dash or steering gear.** The engine is brought forward until clear of dash, then lifted up to the right, to clear the steering gear.



A—Flange on end of crank shaft bolted to fly wheel.

B—Magneto coils or spools, of which there are 16. They remain stationary.

C—Magnets on fly wheel of which there are also 16. They revolve with fly wheel.

D—Bolts supporting the magnets.

E —Fly wheel, bolted to flange on crankshaft.

F —Planetary gears, called "sun and planet" type.

G —Clutch discs.

H —Ring which presses against clutch discs when fingers are pressed on by yoke J, which causes clutch adjusting screw (I) to press against ring (H) thereby pressing clutch disc plates (G) together, which causes drive shaft (L) to then transmit power through drive shaft to rear axle.

I —Adjusting screw for pressure of finger against ring and clutch. There are three of these and three fingers.

J —Yoke which throws clutch "in" and "out" by movement of side hand lever (see chart 325.)

K—Spring which forces collar against fingers.

L —Transmission shaft connecting with universal joint, thence drive shaft.

M—Collar supporting thrust of rear of spring.

N —Transmission brake band, applied by movement of foot lever, marked (B), (see chart 325).

O —Slow speed band applied by foot lever marked (C). The same lever operates clutch.

P —Reverse band applied by foot lever, marked (R), chart 325.

When No. 1 is on	No. 2 is on	No. 4 is on	No. 3 is on
FIRING	Compression	Suction	Exhaust
Exhaust	FIRING	Compression	Suction
Suction	Exhaust	FIRING	Compression
Compression	Suction	Exhaust	FIRING

Engine—note, there are four pistons. The crank shaft is of the 180° type. When pistons No. 1 & 4 are up; No. 2 & 3 are down.

The Ford engine fires, 1, 2, 4, 3—that is, say No. 1 was starting down on firing stroke, No. 2 would be coming up on compression and would fire next; No. 4 would be going down on suction because it would fire after No. 2; No. 3 would be coming up on exhaust.

***Cam shaft speed**—Cam shaft runs ½ the speed of crank shaft, because the cam shaft gear is twice the size of the crank shaft gear. (see timing gear above and note small gear on end of crank shaft and larger cam gear on end of cam shaft.)

Cam shaft gear has 42 teeth and is 5⅛ inches in diameter. The crank shaft gear has 21 teeth and is 2⅝ inch in diameter.

CHART NO. 331—Sectional View of Engine. Plan View from Beneath. Firing Order. Valve Arrangement.

*Note: By mistake, only four cams are shown on cam shaft. There are eight as per fig. 9, page 86. See fig. 33, chart 330 for location of valves. Also see Insert No. 2

Inlet valve opens 1/16 in. (piston travel) after top center on 1st stroke (as piston is 5/16 in. above cyl. when at top—it is now ¼ in. above.)

Inlet valve closes 9/16 in. after bottom center on 2d stroke. Measurement from top of cyl. to top of piston being 3⅛".

Exhaust valve opens 5/16 in. before bottom center on 3d stroke. Measurement from top of cyl. to top of piston being 3⅜".

Exhaust valve closes on top center of 4th stroke.
Note when piston is at top of stroke it is 5/16 in. above cyl. casting.

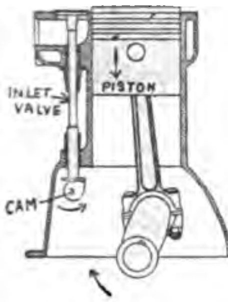


Fig. 41.

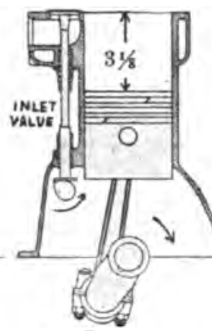

Fig. 42.

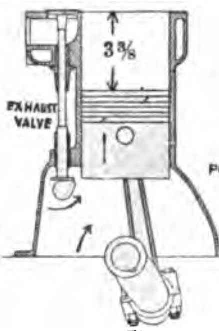

Fig. 43.

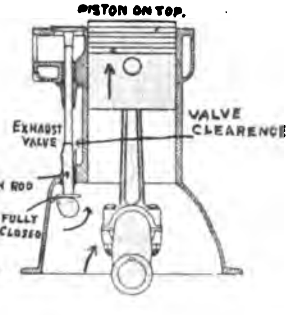

Fig. 44.

Opening and Closing of Valves.

1913 and later model "T" Ford engines, the valves open and close as per figs. 41, 42, 43, 44.

Prior to 1913, the inlet opened 7/64" past top and closed ⅝" past bottom. Exhaust opened ⅝" before bottom, closed 1/64" past top. Above figures may vary slightly on different engines, especially on old engines with parts worn.

Valve Timing.

As the valves are properly timed at the factory it is not necessary to retime same unless the cam shaft, time gears, or valves were removed in overhauling.

In this case, the time gears must be meshed properly as follows: Place top of piston of No. 1 cylinder within approximately ⅝" of top of cylinder block by turning crankshaft in direction of rotation. Turn camshaft (gears out of mesh), until exhaust cam is at a point where exhaust valve is near closing (fig. 45); the exhaust cam should point away from the (O) mark on the camshaft and crankshaft gear, which are directly opposite, or in line with the center of point, or nose of cam. At this point, the tooth of the crankshaft gear, indicated by (O) mark will mesh **between** the two teeth of the camshaft gear (large gear) at the (O) mark.

After meshing the gears in this manner, the inlet valve of No. 1 cylinder should be closed and exhaust valve open.

When gears are meshed as above, then exhaust valve of No. 1 cylinder (fig. 45), is just at the point of closing, but is not fully closed, but by the time piston reaches top of its stroke the valve will be fully closed as per fig. 44. Also note that as No. 2 cylinder will be the next cylinder to fire, the roller of commutator should be almost on the (No. 2) commutator segment, depending upon whether the spark lever is advanced or retarded (see fig. 87, page 803 and fig. 2, page 316).

If the camshaft is removed at any time from the shaft, in replacing the gear see that the dished side is out and that the first cam (exhaust cam) point is in opposite direction from the (O) mark on the camshaft time gear per fig. 45.

To check valve timing when camshaft or gears have not been removed, first remove cyl. head and check the inlet valve opening and exhaust valve closing of each cylinder by following measurements in figs. 41, 44.

These measurements may not check accurately, and if out to any great extent, then see if camshaft, bearings, push rods or valves are worn. If not, and gears are meshed correctly then the variance may be in the manufacturing limit. **See that valve clearance is properly adjusted** before checking valve timing.

Spiral or helical tooth timing gears are now used.

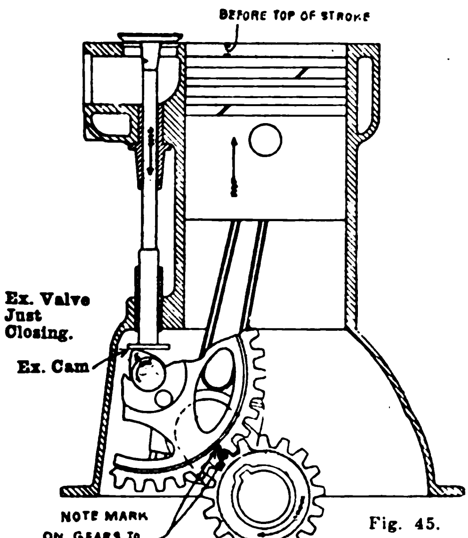

Fig. 45.

Valve Clearance.

The correct clearance between push rod and valve stem is .022" to .028". The gap should be measured of course, when cam point, or nose of cam is **not** lifting valve, but when push rod is on the heel of cam, the principle of which is more clearly shown in figs. 2 & 3, page 94.

To determine when valve opens and closes, insert first, a .001" thickness gage between valve stem and push rod and have some one crank engine. The instant the thickness gage will **not move** the valve has opened. The instant it will move after being held tight, the valve is closed and the gap between push rod and valve stem should then be accurately measured and should be .022" to .028".

If clearance is greater, the valve will open late and close early, resulting in uneven running of engine. In this case, the **push rod is worn** (see fig. 36, page 791), or **valve stem is too short** and a new valve should be substituted, or old one "drawn-out" by peening lower end to lengthen it, or valve adjusters (fig. 61, page 791) can be used. **If clearance is less, valve will open early and close late,** or if no clearance at all, then it will remain partially open all the time. In this case, **stem is too long** and a small amount of stock should be ground from the end of valve stem.

When fitting new push rods, new valves should also be fitted. **When fitting new valves,** they should be ground in, see pages 630, 631.

Valve clearance on the Ford engine is non-adjustable, see page 635 for meaning of this.

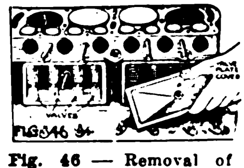

Fig. 46 — Removal of valve cover to adjust clearance.

CHART NO. 332—Valve Timing. Valve Clearance. Meshing Timing Gears.

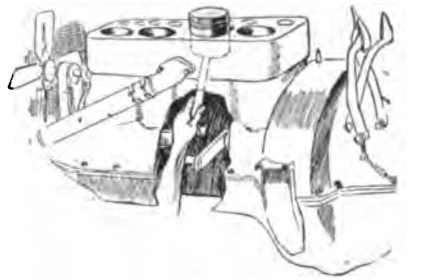

Fig 47—Removing conecting rod and piston: One method of getting at the piston is to take off the cylinder-head, remove the cover from the bottom of the crank case and, by reaching through this, remove the bolts holding the connecting-rod lower bearings in place. After the connecting-rod bearing caps are removed, the piston can be pushed up though the top of the cylinder.

The method of removing the piston is clearly illustrated. (Motor Age.)

To remove the piston pin; loosen connecting rod clamp screw.

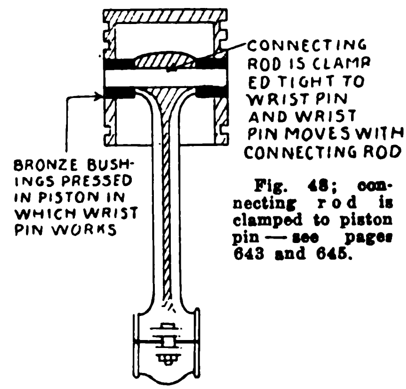

Fig. 48; connecting rod is clamped to piston pin — see pages 643 and 645.

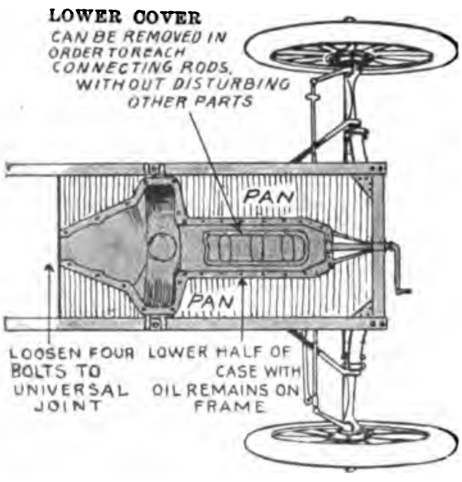

Fig. 49—All parts of Ford engine can be **removed in one unit** and lower part or oil pan, left on frame as it seldom needs to be removed.

To remove lower crank case cover, it is necessary to take out 14 capscrews (5/16x7/16 inch.) Be careful to not destroy gasket and watch for oil in pockets under connecting rods. Note the lower crank case cover is the part upper arrow points to.

*Connecting Rod Bearings.

Loose connecting rod bearings cause a rattle, or light knock, especially at light loads and high speeds. Heavier loads seem to steady the connecting rods.

Long wear, pounding due to carbon, a spark too far advanced, or forcing the engine to labor on high gear; as well as lack of, or poor quality of oil, are the chief causes of loose connecting rod bearings.

It is not necessary to drain the oil from the base, when making repairs to the connecting rod bearings, as the normal oil level is below the detachable plate on the bottom of the crankcase (see fig. 6, page 772.)

Adjusting Connecting Rod Bearings.

The connecting rod bearings may be adjusted, without taking out of the engine, as follows: (A) remove crank case lower cover plate on bottom of crank case and exposing the connecting rods; (B) remove the first connecting rod bearing cap, and draw-file the ends—just a little at a time; (C) replace the cap, being careful to see that punch marks correspond, and tighten bolts until it fits shaft snug; (D) test bearing for tightness by turning engine over by the starting handle; (E) now loosen the bearing and proceed to fit the other bearings in the same manner; (F) after each bearing has been properly fitted and tested, then tighten the cap bolts.

There is a possibility of getting the bearings too tight and under such conditions the babbitt is liable to cut out quickly, unless the engine is run slowly at the start. After adjusting the bearings, jack up the rear wheels and let the engine run slowly for about two hours (keeping it well supplied with water and oil) before going out on the road.

Removing No. 4 Connecting Rod Cap.

Bring the No. 4 connecting rod about halfway up on the up stroke. Remove the cotter pin and nut, from the right connecting rod bolt. Now turn crankshaft over, by means of the starting crank, until the connecting rod cap is about halfway down on the other side. Pull out the other cotter pin and remove the nut from the bolt. Ford socket wrench No. 2322 can be used, if a couple of inches is cut off from the handle. Or, Walden wrench No. 5810 is specially made to reach this nut, and is very useful for this purpose (see chart 341.)

Be careful that the nuts and parts do not fall into the transmission case, and mark the connecting rod cap with a center punch before taking it off, so that it can be replaced in exactly the same position.

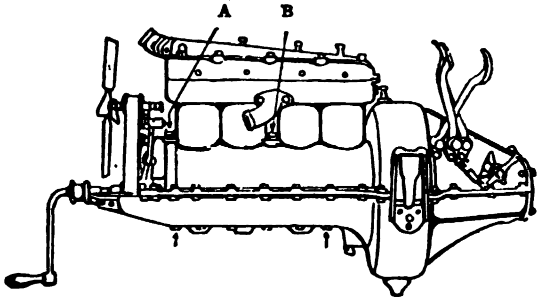
Removing Piston and Connecting Rods.

See fig. 47 above.

When connecting rods become worn, they may be returned, prepaid, to the nearest Ford agent or branch house for exchange at a price of 75 cents each to cover the cost of rebabbitting. It is not advisable for any owner or repair shop to attempt the rebabbitting of connecting rods or main bearings, for without a special jig in which to form the bearings, satisfactory results will not be obtained. The constant tapping of a loose connecting rod on the crank shaft will eventually produce crystallization of the steel—result, broken crank shaft and possibly other parts of the engine damaged.

HART NO. 333—Connecting Rod and Bearings. Removing Pistons and Connecting Rods. Three Point Suspension of Power Plant.

See also page 641, 642, 643.



†Fig. 50—To remove the center and front main bearing—remove nuts at (A) and (B) and draw long crank shaft bearing bolts (½"x6$\frac{1}{16}$"x20 threads) out from bottom, when lower bearing caps can be removed. It is not necessary to remove engine from frame.

To remove rear main bearing it is necessary to remove the engine from frame. If a special Ford wrench No. 1929 is used, one fly wheel bolt, holding fly wheel to end of crank shaft (see page 784) can be removed without further dismantling and then remove the two bearing nuts off lower part and bearing cap will lift off.

To remove the cylinder head: Disconnect water hose from top plate,* after first draining radiator, disconnect spark plug wires. Remove cap screws holding head to cylinders and lift off. This can be done without removing engine from frame. (see also page 783).

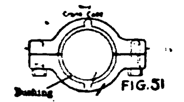


Fig. 51—Illustration showing the main bearing cap and bearing bushing, which is babbitt lined. Shims between bearing cap and upper bearing not shown.

The three main bearings on crankshaft are babbitted. On the old 1910 models, the upper halves of the main bearings were plain iron and not babbitted.

Crank Shaft Main Bearings.

Wear of the main bearings of the crankshaft will be evident by a rather heavy pound or thud, especially when the engine is pulling hard under a heavy load. (see page 639.)

Wear of these main bearings may be due to; long use; not enough, or poor quality oil; allowing the engine to knock; from carrying the spark too far advanced, or carbon in the cylinders; to a sprung crankshaft; or failure to drain out the old oil regularly.

The rear main bearing carries the heaviest load and is usually the first to show signs of wear. This rear bearing supports the flywheel, the magneto and one end of the transmission, in addition to supporting the crankshaft against the thrust of the pistons.

Looseness in the rear main bearing, may be detected by running the engine on No. 4 cylinder and having the throttle wide open—this will show up a loose main bearing.

The rear main bearing cannot be tightened, without taking the engine out of the car as explained under fig. 50. The middle bearing can be tightened, without taking the engine out of the car, but seldom needs adjusting unless the other bearings need it also.

**Adjusting Bearings.

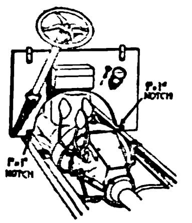

Fig. 51A—To remove the Ford engine from the frame without raising body from frame; take a hacksaw and cut out a square 1 in. by 1 in. on each side of the dash. (Motor World.)

First: Take engine out of the car, remove crank case, transmission cover, cylinder head, pistons, connecting rods, transmission and magneto coils. Remove the three babbitted caps and clean the bearing surfaces with gasoline. Prussian blue is then applied, or red lead, to the bearing surfaces of the crank shaft, which will enable one to determine whether a perfect bearing surface is obtained when fitting the caps.

Second; put the rear cap in position first, and tighten it up as much as possible being careful to not strip the bolt threads. Bearing, when properly fitted will permit the crank shaft moving with one hand.

If it cannot be turned with one hand, between the bearing surface, contact is too close, and the cap requires shimming up, one or two thin shims usually being sufficient.

If the crank shaft moves too easily with one hand, the shims should be removed and the steel surface of the cap filed off, thereby causing it to set closer.

Third; after the cap has been removed, note whether the blue or red "spottings" indicate a full bearing the length of the cap. If "spottings" do not show a true bearing surface, the babbitt should be scraped and the cap refitted until it fits properly.

Fourth; the rear cap can now be laid aside and the adjustment of the center bearing can be made in the same manner. The operation can be repeated with the front bearing.

Fifth; after you have obtained the proper adjustment of each bearing, the babbitt surface should be cleaned carefully and a little lubricating oil placed on the bearings, and the crank shaft; then draw the caps up as close as possible—making sure the necessary shims are in place. There is no danger of getting the cap bolts too tight, as the shim under the cap and the oil between the bearing surfaces will prevent the metal being drawn into too close. Put oil on the bearing surfaces, otherwise the babbitt is apt to cut out when the engine is started before the oil in the crank case can get into the bearing. When the crank case and transmission cover on the engine is replaced, a new set of felt gaskets to prevent oil leaks, should be fitted.

CHART NO. 334—Crank Shaft Main Bearings. Adjusting Bearings.

*See fig. 53, page 789. See foot note, page 814 relative to counterbalances for Ford crank shafts.

**See also pages 641, 642, 643. †Unless bearing is burned out or badly worn, the center and front bearing ca be taken up by removing bottom cover without removing engine. Remove cotter pins from the bolts betwee No. 2 and No. 3 cyl. and while one man has a wrench on the nuts, another man beneath the car turns the bolt out. If there are shims, loosen bolts just enough to pull shims out with a pair of pliers. If no shims, re move cap and file as per page 643. Be sure and mark caps if removed.

To Remove Crank Shaft.

First remove connecting rods and the main bearings, disconnect the bolts holding the flywheel to the flange of the crankshaft, using Ford special wrench No. 1929.

Removing the Camshaft.

It is sometimes necessary to remove the camshaft in order to install new push rods, or to replace worn camshaft bearings, as the bearings are sometimes the source of knocks that are difficult to locate.

It is a comparatively easy matter to remove the camshaft when the engine is out of the car, but, contrary to the opinion of many owners of Ford cars, it is also fairly easy to remove the camshaft without removing the engine.

Procedure for camshaft removal: Remove the pin which holds the fan belt pulley on the crankshaft. (see fig. 78A, page 796.) Drive the fan belt pulley forward. Remove the cap screws, which hold the cylinder front cover to the cylinder block. Remove the commutator brush assembly, after driving out the pin which holds it to the cam shaft. Now the cylinder front cover can be removed. Next, remove the two cap screws in the side of the cylinder block which hold the camshaft bearings in place.

It may now be possible to pull out the camshaft with its bearings, but if not, the plate on the lower part of the crank case should be removed, after the cap screws which hold this plate to the crank case have been taken out.

Then a drift, or brass bar, can be used to drive the camshaft out from below, holding the end of the brass bar against one of the cams and striking the other end of the bar with a hammer. Care should be taken not to punch a hole through the cast iron cylinder block while doing this part of the work.

After the camshaft has been removed, the push rods will drop down and can be removed through the opening in the bottom of the crank case. Be sure to remove all the push rods.

Installing New Push Rods.

Place the new push rods in the guides. Small holes, near the top of each push rod, will now be noticed. After putting the push rods in place, slip nails, or a piece of wire, through these holes, to keep them in position while the camshaft is being replaced. Then the camshaft and its bearings can be driven in, and the cap screws (which hold the bearings) tightened.

The marks on the small crank shaft gear and on the large timing gear should be placed together, and the valves tested to make certain that the valves open and close at the proper time. Then the front cylinder cover plate should be replaced, and the timer brush assembly and also the timer cover. Then the fan belt pulley and the starting crank pin, and finally the fan belt. (Fordowner.)

Causes and Cures of Overheating.*

Carbon, in the cylinders.
Remove the cylinder head and scrape out the carbon, as directed on pages 790 and 624.

Driving on low gear.
The engine should not be raced, when driving on low gear, and the spark should be well advanced, because the engine speed is comparatively high. Do not use low, when high speed can be used without straining the engine.

Spark retarded too far.
Keep the spark advanced as far as possible, without causing the engine to knock. As the throttle is opened and the engine slows down, it is necessary to retard the spark.

Poor ignition.
If the engine is misfiring it is necessary to open the throttle much wider and retard the spark; this tends to cause overheating.

Insufficient or poor quality of oil.
Lack of oil will cause such friction between the pistons and the cylinder walls that the engine will overheat and the pistons may stick. Poor oil burns up, or becomes thin and runs away so quickly that the parts are left practically without oil. Use good oil—it costs less in the long run.

Racing the engine.
Close the throttle when the clutch is disengaged, and so save gasoline and prevent overheating.

Clogged muffler; too rich a mixture or too much oil will deposit soot in the muffler and by preventing the escape of the exhaust, will cause overheating. Clean the muffler by disassembling it. (see page 84.)

Water frozen—steams (see page 579-193).
To thaw out—open drain cock—water usually freezes at bottom of radiator—therefore pour hot water on bottom until circulation starts. This will be indicated by water running out of drain cock. Then close drain cock and fill radiator with water and keep engine running. Sometimes when engine steams if a blanket is thrown over the engine and radiator the heat will thaw out bottom of radiator.—see pages 579-193-800.

Fan not working properly.
A broken, or a loose and slipping belt will not rotate the fan fast enough to draw a cooling current of air through the radiator. This will especially tend to cause overheating when the engine is idling or running on low gear. Tighten or replace the belt. Perhaps it may be necessary to bend the fan blades at a slightly sharper angle, in order to draw more air through the radiator. (see fig. 52.)

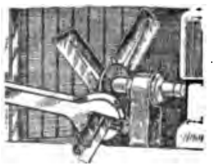

Fig. 52.

Poor water circulation.
Due to low water. As the thermo-syphon system is used the water will cease to circulate as soon as the level falls below the inlet to the radiator. Keep the radiator well filled. (see last paragraph on page 590.) Leaks may lower the water level. The rubber hose connections may have rotted and a flap of rubber on the inside of one of these hose connections may seriously impede the flow of the water.

Don't get alarmed if the water boils occasionally, especially in driving through mud and deep sand or up long hills in extremely warm weather. Remember that the engine develops the greatest efficiency when the water is heated nearly to the boiling point. But if there is persistent overheating when the engine is working under ordinary conditions—find the cause of the trouble and remedy it. The chances are that the difficulty lies in improper driving or carbonized cylinders.

No trouble can result rfom the filling of a heated radiator with cold water—providing the water system is not entirely empty—in which case the engine should be allowed to cool before the cold water is introduced.

CHART NO. 335—Removing Crank and Cam Shafts. Causes and Cures of Overheating.

*See pages 189 and 579.

Ford Radiator Cores.

The Ford radiator has a tubular core with fins, arranged on the order of fig. 5-A, page 190.

The core of a radiator is the principal part (see explanation, page 715) and can be purchased separately from the upper and lower tanks.

The core can often times be purchased cheaper than it can be repaired. For instance, if any great number of tubes, say more than ten, need repairing, then a new core is advisable.

The core is usually measured by its thickness. The Ford radiator is 2⅝" thick.

A firm that makes a specialty of supplying cores to repairmen is the Sheet Metal Works, Chicago, Ill. They make five standard thicknesses, 2", 2¾", 3½, 4", 4½", to fit Ford, Chevrolet, Dodge, Studebaker 6, Cadillac and Maxwell.

Radiator Parts.

The material listed below can be secured of F. L. Curfman, Maryville, Mo. Mr. Curfman also issues a very interesting **booklet on radiator repairing** of a practical nature on repairing both "tubular" and "cellular" radiator cores.

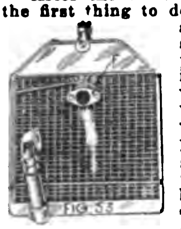
False fins made of tin or brass.
Paint for radiator fins.
Side walls, bottom and lower tanks, cores, filler necks, brass rivets, etc.
Copper tubing tinned, ¼" outside dia. in lengths of 15", 17¼", 20 and 22".
Brass pipes 5/16" tinned, for overflow pipes, 29" long.
Soft sheet brass, hose clamps, drain cocks, etc.

‡Radiator Repair Tools.

Electric flash light for examining close places, also a special magnifying mirror.
Brushes for cleaning; acid swabs, etc.
Soldering irons made special for small places.
Scrapers for close places.
Rubber stoppers. Gasoline torch of special design with a needle point flame.
Torch with larger flame.
Flux and flux squirter.
Air compressor of special design which can be operated from a 1/6 H. P. motor and from lamp socket, to be used for air pressure for testing and for gasoline torch. No tank required.
Gasoline gas generator for use with gasoline torch.
Coil spring for placing in copper overflow tubing so it can be bent, etc.

Testing.

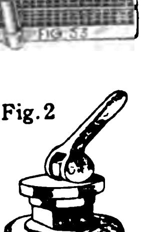
After the removal of the radiator from the car, the first thing to do is to test it. The inlet, outlet and filler cap must be plugged, so that air pressure may be applied to overflow pipe. Then if the radiator be put under water, the bubbles will show where the leaks are.



When removing a radiator, the hose and flange are left on as shown in fig. 53. If radiator is to be repaired, then the lower hose is removed.

The openings in radiator are then stopped up by means of expanding rubber plugs or an arrangement as shown in fig. 2. (Similar plugs can be secured of F. L. Curfman.) One plug is inserted in the intake and another in the water return and another in the filler opening.

Fig. 2



The air pressure is applied to the radiator through the overflow pipe, by slipping rubber hose from air line over the overflow tube. The radiator is then immersed in a tank full of water, and the leaks determined by the bubbles. The leaky parts are then marked. See also, page 194.)

Another method for closing up a radiator for testing, is to solder a piece of tin in filler opening and put a rubber plug in the bottom outlet and bolt a rubber gasket at F, fig. 53. Then place air pressure hose on overflow pipe.

†Repairing.

The radiator is placed on a bench and the leaky part of the tubes heated with a blow torch. When quite hot—a little hotter than boiling—muriatic acid soldering solution is poured through the fins, all over the leaky tubes, to clean their surfaces. The cleaning process is very important.

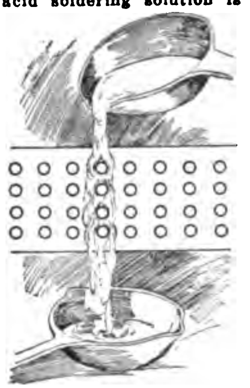


Fig. 1—Illustrating how solder is poured over the leaky radiator tubes

***A ladelful of solder is then melted.** Radiator is bolstered up from the bench on blocks, and the melted solder poured through the fins, over the leaky tubes. Note the method of catching the excess solder.

Then the radiator is turned over and the solder poured in from other side in exactly same manner.

A little more acid is then added and a torch applied to melt the solder and sweat it into all the leaks, closing them permanently.

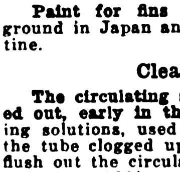
Though leaks and splits of quite a large size may be fixed this way, it is occasionally necessary to tear the radiator down and put in new tubes. The hardest part of the job is tearing the radiator down to the core and building it up again. New cores can be purchased with the top of bottom tank soldered on.

There are many other methods of cleaning and soldering leaks. The leaky parts are often scraped bright with small **scrapers** made from three cornered files with the teeth ground off and then acid applied and soldered with a **soldering iron made especially for this work** by taking a 1½ lb. soldering iron, heat red hot and draw out long and slim, then tin the iron carefully. See also pages 714, 715.

Leak Preventatives.

There are many so called leak preventatives, for instance a cement called **cold solder,** the manufacturers claim, by pasting externally on leak (fig. 6), it will harden and stop a leak temporarily until radiator can be repaired. Stone Solder Co., Cleveland, Ohio.

Fig. 6



Another leak preventative is a chemical mixture of cement which is placed internally into radiator when water is hot. The solution is supposed to pass out the leak in radiator and as it is exposed to the air it hardens and closes the leak. It is claimed that this preparation will also close cracks in water manifolds, etc. See page 715.

Paint for fins can be made from drop black ground in Japan and gold size, thinned with turpentine.

Cleaning a Radiator.

The circulating system should be carefully washed out, early in the spring, because the anti-freezing solutions, used in the winter, are apt to leave the tube clogged up. In summer, it is advisable to flush out the circulating system about once a month (see page 191).

To do this properly the radiator inlet and outlet hose should be disconnected, and the radiator flushed out by allowing the water to enter the filler neck at ordinary pressure, from whence it will flow down through the tubes and out at the drain cock and hose. The water jackets can be flushed out in the same manner.

To remove scale from inner surface of radiator: One method is by using hot water, in which a small amount of ordinary washing soda has been dissolved, afterward rinsing this out with clean water.

For very hard deposits a solution of one quart commercially pure muriatic acid to five gallons of water should be circulated through the cooling system slowly for five minutes.

Another good method is, to one pint of glycerine add enough boiling water to fill the system, then run the motor slowly and drain out after running and flush with fresh water. Reversing the flow of water in flushing also helps.

CHART NO. 335-A—Repairing and Cleaning Radiators. See also, pages 191, 194, 714, 715, 584.

*What is known commercially as "50-50" solder is adapted for this work—see also, pages 714, 715, 711. †See also, page 715. ‡See fig. 20, page 714, for Ford radiator repair outfit.

*Compression and Grinding the Valves.

If the compression is poor, and the pistons and rings fit well, the valve may need grinding or adjusting. The compression can be tested, when the engine is warm, by pulling up slowly on the starting crank. The compression should be springy and elastic, but not as lively as that of other cars, on account of the drag and friction in the Ford transmission. (see pages 627 to 629.)

Removing Valves for Grinding.

Drain radiator. Remove cylinder head, and the valve covers on the right side of the engine. Use valve lifting tool (fig. 61, page 633 also see chart 343) to compress valve springs and pull the pins out of the ends of the valve stems. Then valves can be pulled out.

Grinding the Valves.

A good grinding paste can be made of ground glass and oil—obtainable from auto supply houses. One method, is to put a small amount in a can top and add a spoonful or two of kerosene and a few drops of lubricating oil to make a thin paste.

Place the mixture on the bevel face of the valve sparingly. Place a spring under valve as shown on page 631. Put the valve in position on the valve seat, and rotate it back and forth (about a quarter turn) a few times, with a grinding tool. (see page 616.) Then lift slightly from the seat, change the position and continue the rotation and keep on repeating this operation until the bearing surface is smooth and bright. The valve should not be turned through a complete rotation, as this is apt to cause scratches running around the entire circumference of the valve and seat.

When the grinding is completed remove the valve from the cylinder, thoroughly washed with kerosene, and wipe out the valve seat thoroughly. Care should be taken that none of the abrasive gets into the cylinders or valve guides. This can be avoided if the grinding paste is applied sparingly to the bevel face of the valve. (see pages 630 to 633.)

When the valve seat is worn badly or seamed, it is then advisable to have it reseated with a valve seating tool. Care should be exercised against making too deep a cut, otherwise the retiming of the valve will be necessary. (see chart 337.)

Valve Springs.

If the valves fail to seat properly, it may be due to weak or broken springs. Weak inlet springs would probably not affect the running of the engine, but weak exhaust valve springs cause uneven action, which is difficult to locate.

It will cause a lag in the engine due to the exhaust valve not closing instantly, and the result will be, a certain percentage of the charge under compression escapes, greatly reducing the force of the explosion.

A weak valve spring can usually be detected by the following method: Remove the valve plate (fig. 46, page 785) and insert a screw driver between the coils of the spring while the engine is running. If the extra tension thus produced causes the engine to pick up speed, the spring is weak and a new one should be replaced.

Valve springs consist of 11¼ coils of No. 104 music wire, complete spring is 2⅞ inches long and 31/32 inch outside diameter.

**Causes of Engine Knocks.

(1) **Carbon,** is the most frequent cause of engine knocks.
(2) **The spark too far advanced,** will waste power and cause a knock.
(3) **Loose connecting rod bearings,** will cause knocks.
(4) **Worn crank shaft main bearings cause knocks.**
(5) **Piston slap,** due to loose piston.
(6) **Worn or broken piston rings,** will cause a light knock.
(7) **Piston striking the cylinder head gasket.**
(8) **Loose camshaft bearings.**
(9) **Valve tappets out of adjustment,** or badly worn, will cause noise.

How to Distinguish Knocks.

(1) The carbon knock is a clear, hollow sound, most noticeable in climbing sharp grades, particularly when the engine is heated. It is also indicated by a sharp rap immediately on advancing the throttle.
(2) Too advanced spark will be indicated by a dull knock in the engine.
(3) The connecting rod knock sounds like the distant tapping of steel with a small hammer, and is readily distinguished when the car is allowed to run idly down grade—or upon speeding the car to twenty five miles an hour, then suddenly closing the throttle the tapping will be very distinct.
(4) The crank shaft main bearing knock can be distinguished, when the car is going uphill, as a dull thud.
(5) The loose piston knock is heard only upon suddenly opening the throttle, when the sound produced might be likened to a rattle. (see also pages 635 and 637 to 639.)

Before and After Carbon Cleaning.

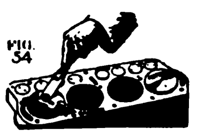
First, drain the water off by opening the pet cock at the bottom of the radiator; then disconnect the wires at the top of the engine and also the radiator connection attached to the radiator. Remove the 15 cap screws which holds the cylinder head in place. Take off the cylinder head and, with a putty knife or screw driver, scrape from the cylinder and piston heads the carbonized matter (as per fig. 54) being careful to prevent the specks of carbon from getting into the cylinders or other openings.

In replacing the cylinder head gasket turn the engine over so that No. 1 and No. 4 pistons are at top center; place the gasket in position over the pistons and then put the cylinder head in place. Be sure and draw the cylinder head capscrews down evenly (i. e., give each one a few turns at a time); do not tighten them at one end before drawing them up at the other.

Removing Carbon.

Fig. 54—Carbon removal is most easily done with a putty knife, after the cylinder head has been removed. The flexible putty knife follows the surface better than the stiff and narrow blade of a screwdriver. Do not get the carbon in the openings into the water jacket. This would tend to impede the flow of the water and might cause overheating of the engine. The openings into the water jackets and the holes for the cylinder head bolts can be plugged with wooden plugs, or pieces of cloth, until the scraping has been completed. (see page 624.)

FIG. 54



HART NO. 336—Grinding Valves. Valve Springs. Causes of Knocks. Carbon Removal.
ee pages 793 and 817. **See also pages 635 to 639.

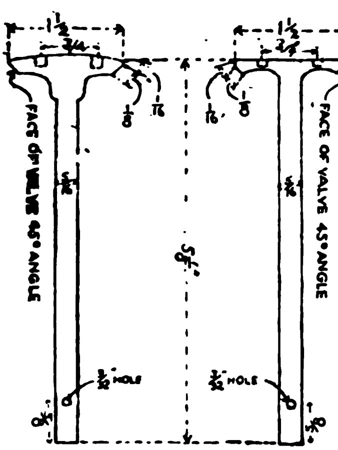


Fig. 55. Fig. 56.

†Fig. 55 — Dimensions of finished Cast iron head valve (standard.)

Fig. 56 — Dimensions of finished Tungsten valve Made by Rich Tool Co., Railway Exchange Bldg., Chicago, Ill.

(Shape of valve is more like one shown in fig. 61).

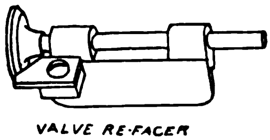

Fig. 59—Valve refacer: When Ford valves are badly pitted it is nearly impossible to get a perfect seat and the tool shown is designed to overcome this difficulty by refacing the valve instead of grinding (see also page 682).

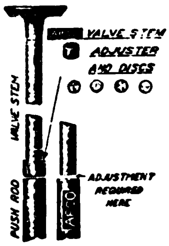

Fig. 61—Valve clearance adjusters: When the space between the end of the push rod (fig. 44, chart 382) and the end of the valve stem is more than 1/32 inch (see page 785 this instruction) then a clicking noise is the result. As the Ford valve has no means of adjustment it is remedied by either installing new valves and **push rods or using adjusters as shown in this illustration.

Fig. 57 — Oversize valve stems are necessary when worn valve guides are reamed out. The standard oversize valve stem is 1/64 inch, (or in other words the valve guide is reamed that much) larger. If the standard valve stem was 5/16 inch, then it would be 1/64" larger or 21/64" di.

Worn valve guides admit air to the mixture which causes misfiring, bad starting and noise.

Ford valve guides are a part of the cylinder casting and cannot be renewed. Reaming and fitting oversize valves is a better method than to ream the guide large enough to put in a bushing. Unless a great deal of metal was removed, the bushing would be so thin that it would not last long.

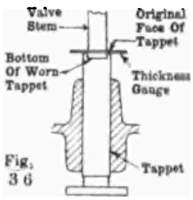

Fig. 36—If valve tappet becomes worn with a depression in end of tappet, this would throw the valve out of time if clearance was measured with thickness on top, or sides of depression. Install new tappet, also valve. (see page 785, "valve clearance.")

A reamer 29/64" is used to ream push rod or tappet holes 1/64" oversize and a 21/64" reamer for reaming valve stem guides 1/16" oversize.

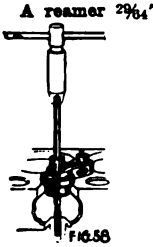

Fig. 58—A valve guide reamer: When reaming the valve guides it is necessary to ream true, therefore a guide is necessary, the guide is shown clamped to cylinder head. The reamer is then passed through the guide and turned by a hand tap wrench.

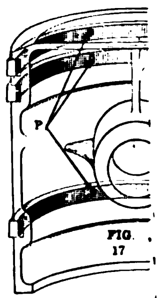
‡**Ford piston rings:** are cut with a .002" taper so that the ring will bear on the lower edge. This is done so the ring will scrape the surplus oil from the cylinder wall on the down stroke, thus preventing an excess of oil getting to compression chamber.



There is a punch mark on the inside, upper edge of the Ford rings (see P, fig. 17). On the earlier rings, there was a file mark in upper edge, to show which side to place up. If ring is upside down, it will have a tendency to pump oil. See also, pages 792 and 793. **Ring gap clearance,** see page 649. Rings are softer than cyl. walls and become under size in time and should be replaced after 10,000 miles.

Fig. 60—Valve seat reamer: is used for the same purpose in the valve seat as the refacer is used on the valve face. Just enough reaming is necessary to remove the pitting.*

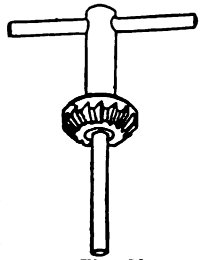


Fig. 60.

Can Ford valves be enlarged? This question is often asked. There is hardly enough metal to permit reaming out the valve ports more than 5/16 inch. The diameter of the standard Ford valve is 1¼ inches (measured at the seat.) Reaming out valve seats to make them larger, is attended with grave risks of cutting through the metal and ruining the cylinder block, especially if the cores were not set exactly true when the casting was made.

Pistons: See page 645 explaining the three conditions which necessitates piston replacement. On a repair job, a Ford piston should fit to bore of cylinder so that a .004" thickness gage, placed between piston and cylinder wall is tight and at .003" is loose. On commercial jobs pistons may be fitted so that at .006" gage will be tight, but the pistons are liable to slap and be noisy until warmed up.

The Ford piston is .010" smaller at head than at skirt. **Leaky pistons,** see page 656.

Overhead valves on Ford engines with 16 valves for racing purposes are offered by Laurel Motors Corpn., Anderson, Ind. and Craig Hunt Co., Indianapolis. It is claimed this will give engine increased speed. It is necessary to use a larger radiator and circulating pump however, due to increase of heat.

CHART NO. 337—Valve Dimensions. Valve Adjusters. Valve Guide Reamer. Valve Refacer.

*There is a limit to the amount of reaming that can be done. If reamed too often, eventually the valves will be lowered enough to form a pocket. (see fig. 8, page 712.) **Push-rods 1/64-in. oversize can be secured of supply houses. †The exact dimensions in thousandths part of an inch of the Ford valve is as follows: dia. valve head 1.421875; dia. of valve stem .811; length of valve stem 4.976".

Piston and connecting rod aligning tools, bearing fitting gauge and other Ford "Speed-up" tools can be secured of Stevens Co., 375 Broadway, N. Y. ‡Now machined with a groove near the edge which should be towards top when placed on piston.

Pistons—Cast Iron.

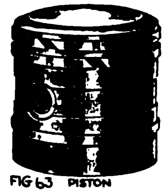

FIG 63 PISTON

Fig. 63—The standard Ford piston is 3¾ inches diameter. The piston pin* is the oscillating type as explained on page 645. Therefore **bushings are necessary in the bosses for the piston pin to oscillate in. The pistons come with the bushings fitted. †Oversizes which can be secured are given on page 609, see also, page 791.

Rings—There are three rings, two placed above and one below, as shown in fig. 63. They measure 3¾ inches diameter by ¼ inch width (about .004 less). Rings to fit oversize pistons can also be secured. (see pages 653 to 659, for ring fitting, etc., also page 609, 791 and 649).

The rings are eccentric and thinner at the ends. Thickness at center is about .150 inch, at ends .085 inch. See also, page 791, 649.

Aluminum Ford Pistons.

FIG.64

Fig. 64—Aluminum pistons also called "Lynite," are being advocated by various manufacturers. They claim that by reducing the weight of the reciprocating parts it lessens the vibration and permits quicker "pick-up" and higher engine speeds.

Aluminum expands more rapidly than cast iron. Hence, these pistons must be fitted with greater clearance to keep them from sticking in the cylinders when the engine becomes very hot.

Clearance varies according to design and type of piston and speed of engine.

For average speeds; .007 to .008 at skirt, and .014 to .016 at top—see also, page 791.

For racing; 60 to 70 m. p. h., .014 to .015 at skirt and .024 to .027 at top.

As aluminum conducts the heat away more rapidly, it is claimed that less carbon forms on the top of an aluminum piston. It is also claimed that there is less friction between piston and cylinder walls, and that they cause less wear on the cast iron cylinder walls.

Most aluminum pistons are supplied with some form of special piston rings, which are intended to prevent the leakage of the gases, thus increasing both the power and the economy. The extra clearance, when cold, is supposed to make the engine easier to crank, but unless carefully fitted, aluminum pistons are apt to slap (see page 637) and rattle at low engine speeds, until they become warmed up and expand to a more perfect fit.

‡The McQuay-Norris Co., of St. Louis, Mo., manufacturers of the "Lynite" Ford piston, state that the pistons they supply can be furnished in standard 3¾ inches diameter and 1/32 inch larger or to be exact 31 thousandths oversize. Also by special order any intermediate size (in thousandths of an inch) between the two dimensions just given. In ordering odd sizes, the exact diameter of cyl. bore must be given in order that the proper clearance can be allowed for pistons.

When ordering pistons always state if "standard" or "oversize" is wanted and if latter, caliper cylinder walls carefully, per page 649.

The Butler Mfg. Co. of Indianapolis, supply aluminum pistons in sizes .002 to 1/16 inch and special orders 3/32 inch larger than the standard size of 3¾ inches. They also state that from .0020 to .0025 clearance is allowed. They further state that 3/32 inch is the limit for reboring to oversize, (see pages 651 and 645 for piston clearance etc.)

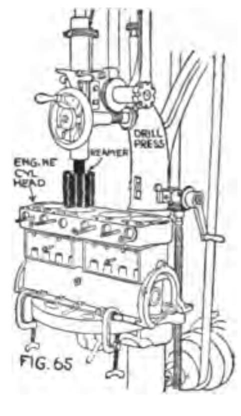

FIG. 65

†Fig. 65 shows a reamer which can be fitted to an ordinary drill press. Reboring is best however, The American reboring tool, which can be operated by hand or in a 20" drill press can be secured of Ford Branches.

‡Enlarging Ford Cylinders.

When oversize pistons are fitted to cylinders it is usual to rebore, ream or grind the cylinders out to the proper size. There are different methods for doing this as explained on pages 653, 654 and 609. In some instances, after an engine has been driven for 10 to 20 thousand miles, the walls may wear slightly and a slight oversize piston may be fitted without enlarging cylinder.†

Aligning Reamer.

Fig. 66—Is a reamer designed to ream all three main bearings simultaneously and saves much time in scraping and refitting bearings.

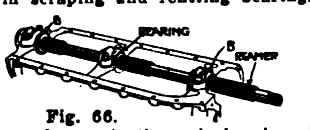

Fig. 66.

The unequal distribution of weight and driving strain on the crank shaft of a Ford engine naturally causes unequal wear in the main bearing. It can be seen that tightening up only on the bearing caps will spring the shaft out of line and throw additional strain on the bearings, causing them to wear loose again very rapidly. This reamer will bring all bearings to proper size and perfect alignment. An allowance of .0025 inch is made for wear of crank shaft.

This reamer can also be used for reaming the connecting rod lower bearings, as they are the same diameter as the main bearings. (Stevens Co., N. Y.)

††Special Reamers For Ford.

Fig. 67—Expanding reamer: A good set of reamers are very essential to the repairman. This particular reamer marketed by Stevens Co., 375 Broadway, N. Y. is an expanding type. They are ground .005 inch undersize and can be brought up to .005 inch oversize. This is an added advantage.

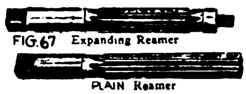

FIG.67 Expanding Reamer

PLAIN Reamer

Reamers are used for reaming out such parts as piston pin bushings, steering spring bushings, transmission triple gear bushings, cam shaft front and rear bushings etc. In fact they are indespensible to the repairman—see also, page 791.

Reamer for spindle body and spindle arm bushing: A 2-in-1 reamer for front axle bushings. The 5-inch section reams the spindle body bushings in perfect alignment at one operation.

The 1-inch section is for use in the spindle arm bushing, price each $2.40.

Reamer for piston pin bushing: Used for reaming through both the piston pin bushings for perfect alignment of piston pins, price each $1.75.

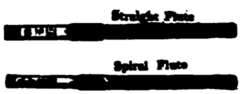

Fig. 68—**Reamers are usually made with either straight or spiral flutes** (see page 706). Stevens Co., 375 Broadway, N. Y. supply reamers.

CHART NO. 338—Pistons; standard and oversize. Cast Iron and Aluminum. Reamers for Cylinders, Main-Bearing, Spindles, etc.

*Piston pin is 47/64 inch dia. x 3½ inches long. ‡See advertisement of South Bend Lathe Works.
**Piston pin bushings (pairs) are phosphor bronze, 15/16 inch dia. x 1 7/32 inches long.
†Standard oversize pistons supplied by Ford Co.—see page 609. .0025 can be used in worn cylinders without reboring—but by carefully lapping. If cylinder is out or round then reboring is necessary. ‡This concern state they have discontinued the manufacture of aluminum pistons. ††**If cylinder is out of round then reboring is necessary. Cylinder Reboring Tools can be secured of the Universal Tool Co., Inc., 435 Woodward Ave., Detroit.** This firm also manufactures a Main Bearing Babbitting and Boring Equipment suitable for Fords and Fordson Tractor engines. Write for printed matter on "UTCO" products which are made by them also.

Over-Lubrication of Cylinders.

*When the spark plug is constantly oily or fouled and constantly missing and excess of smoke is emitted out of the exhaust, this indicates that too much oil is working past the piston rings, or at least too much oil is passing into combustion chamber from crank case.

Causes.

(1) The oil level in crank case may be carried too high. It should not be above the upper petcock in the crankcase. (see fig. 6, chart 320).

(2) The front spring may be sagged. If the front end of the engine is lower than the rear, the oil will not drain back into the sump until there is too much oil under the front piston. A heavier pad between the front spring and the frame will level the engine.

(3) The cylinder bore may be worn oval by the side thrust of the connecting rods on the pistons, or the cylinder walls may be grooved and scored. All four cylinders should be rebored at the same time, and fitted with oversize pistons.

(4) The points of the spark plugs may be too close together, thus allowing oil to short-circuit them too easily. Bend the points slightly farther apart and (not over 1/32 inch) bend the side electrode upward, so that the oil will drain off to one side and not collect between the points.

(5) Leaky piston rings—page 653 and 655.

A broken piston ring will be indicated by a click or light knock, by loss of compression, and by smoke from the oil filler pipe or crankcase breather.

Well fitted pistons and rings will almost invariably cure trouble caused by overlubrication of the cylinder. If it does not, and none of the above is the cause, then the engine is afflicted with what is termed "**piston pumping oil**" which is explained on page 653 and the remedy is to doctor the rings and piston.

‡Remedying Piston Pumping Oil.

One method is to install a patented leak proof type ring (see page 655.) The patented ring is usually placed at the top, to hold the compression above the piston, but is sometimes placed at the bottom as it is claimed that less oil will be used in this way. The use of all three patented rings, (if a tight fit) will sometimes prevent the walls of cylinders getting a sufficient amount of oil—therefore this must be considered and probably lapping the ring to cylinder as explained on page 657 will help.

Another method, fig. 69—shows a piston doctored to prevent oil leaks; a patent two-piece ring, which is designed to hold the compression. Below the second ring (about four) 5/16 in. holes are drilled through the piston concave walls which allow oil scraped from the cylinder walls by the rings to run through these holes back to crank case.

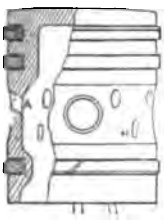

Fig. 69.

The bottom ring has one edge beveled or chamfered as shown in fig. 69. The chamfered edge of the ring should be placed upward, as shown on the piston, so that the chamfered edge will slip over the oil, while the sharp edge on the bottom of the ring will scrape off the excess oil and force it back into the crankcase on the downward stroke. (see also page 653, "piston pumping oil.")

Fig. 70 shows a method of chamfering the lower part of the 3 rings and is usually all that is necessary. This should be tried before fitting a patent ring or drilling piston.

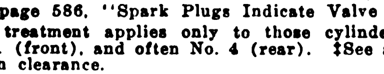

Fig. 70.

To chamfer means to bevel the part (as shown in illustration) with a file or emery wheel. Note illustration gives an idea as to the amount and angle of the chamfer. This will permit cylinders to get oil but will prevent oil working past rings into combustion chamber, providing of course, cylinder walls are not "scored" (cut) see pages 652, 650 and 653.

‡‡Piston Clearance.

Ford pistons should be fitted with a clearance between pistons and cylinder walls of from .002 to .005 inch. Less than .002 inch is apt to cause sticking and more than .005 is apt to cause "piston slap" (see page 637).

Further instructions on the fitting of pistons and rings can be found by referring to pages 651 and 657.

**Increasing Compression.

This means that by reducing the space in the combustion chamber from head of piston to inside top of compression chamber of cylinder—when piston is in its uppermost position—the gas would be compressed tighter, therefore more explosive force when combustion takes place.

Opinions vary on this. For high speed work it might possibly help—but the heating will increase and a circulating pump or larger radiator (special racing type—see page 820) will probably be required. Refer to page 627, under head of "Compression"—also page 817.

The question was recently asked of a manufacturer of Ford parts as follows:

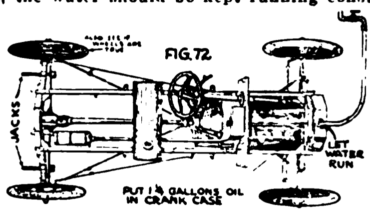
(Q.) Would you advise cutting cylinder base down 1/8 inch to increase compression on engine for racing?

(A.) "It is much easier to plane off the cylinder head. Another method would be to use **special pistons to increase compression 1/8 inch.** We had an experimental machine fitted in this manner and found satisfactory, and is no doubt the most practical way. Increased water capacity is necessary and some form of circulating device such as a pump advisable."

Right here the writer wishes to add that in a recent race tournament of Fords, not one of the engines had increased compression. (see page 817.)

"Running In" Engine.

After engine has been overhauled, new rings, bearings, etc. fitted, it is a good plan to jack up rear wheels per fig. 72, put about 1¼ gallons of lubricating oil in crank case, put water hose in radiator and run engine for several hours to work rings and bearings "in." Note when "running in" an engine, the water should be kept running constantly.



When doing this work, the engine is usually out of the frame of car, therefore another plan would be to place the engine on a stand made for the purpose as in fig. 73 and run engine from a belt from line shaft. This of course is for a repair shop with considerable work. See also page 828.

Many, after fitting parts and first following plan shown in fig. 72, then take car out and run slow and carefully—not over 12 to 15 m. p. h. for the first 500 miles—this is very important as cylinders are liable to be cut. Use plenty good oil. (See p. 655.)

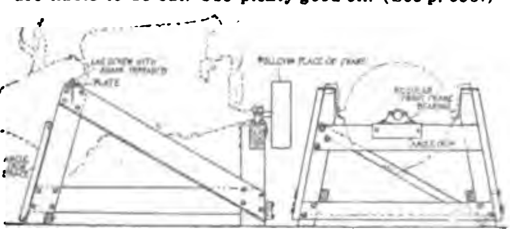


Fig. 73—Engine stand constructed of wood. A regular front bearing bracket of the Ford is attached to stand to form the support for the front end.

CHART NO. 339—Over Lubrication of Cylinders. "Running In" Engine. Increasing Compressio[n]

*See page 586, "Spark Plugs Indicate Valve Condition." **See also pages 640, 629, 817 and 909.

*The treatment applies only to those cylinders in which the spark plugs are constantly oil soaked, usuall[y] No. 1 (front), and often No. 4 (rear). ‡See also, pages 652, 791. ‡‡See page 609, 649, 699, how to measur[e] piston clearance.

*Fair Charges for Overhauling a Ford.

The prices given on this list are for individual repairs, and are the labor charges only. The materials used and the parts installed should be charged for extra, according to the established prices given in the Ford parts price list.

The prices charged are amply high to cover the best quality of work, the work can be guaranteed at these prices, and the repair shop will make a fair profit on the work.

Engine Division.

	Charge for Labor.
Overhaul—	
Engine and transmission	$18.00
Engine only (or engine and transmission out of car)	14.50
Transmission	11.00
Repair	
Burned out bearing	10.50
Main bearing knock	8.50
Put in two or more pistons	6.00
Cylinder knock	5.00
Put in two or more connecting rods or repair oil leak	5.00
Put in one new piston	5.00
Leak in crank case	5.00
Put in one connecting rod	3.75
Grind valves, clean carbon	2.75
Change transmission bands	2.50
Rebore and rebabbitt cylinder block including fitting of pistons	8.00
Rebore cylinder block only	2.00
Tighten transmission gasket cover on case, or rebush transmission	2.50
Cylinder head bolts (stripped)	2.50
Replace crank shaft starting pin	1.50
Cylinder front cover	2.00
Overhaul carburetor	2.00
Braze crank case arm only	1.50
Change cylinder head gasket	1.25
Tighten engine to frame	1.25
Commutator wire loom and brush	1.00
Assemble fly wheel only	1.00
Change carburetor	.75
Leaky door or clean crank case	.60
Change fan pulley assembly	.60
Commutator pull rod ball joint	.50
Leaky carburetor	1.00

Rear System Division.

Overhaul rear axle or install new housing	$6.00
Change rear radius rod	1.50
Replace—	
Rear spring, tie bolt, or new leaf, including graphiting leaves and line up body rear spring tie bolt only	3.00
Rear spring tie bolt only	1.50
Rear axle assembly	3.00
Rebush system	3.00
Repair—	
Install universal joint	2.50
Shaft straighten	1.50
Dope leak, one side	1.00
Install brake shoes, each	1.00
Equalize emergency brakes and fit brake shoes or repair hand brake lever quadrant	1.25
Emergency brake only	.75
Tighten universal joint	.60
Change truss rods, each	.60
Change brake rod supports each	.60
Install or tighten rear spring retainer clip	.60

Front System Division.

Rebush front axle	$5.00
Rebush spindles (each side, $1.50)	3.00
Repair—	
Broken off radius rod ball cap stud	2.50
Straighten front axle	2.50
Front spring tie bolt—or new leaf, including polishing and graphiting leaves	2.00
Front spring or tie bolt—replace only	1.00
Tighten ball cap or replace radius rod	.60

Chassis Division.

Replace steering gear	$3.00
Replace fenders, each	.50
Replace front cross member	6.00
Repair—	
Overhaul radiator	6.00
Remove shock absorbers—oil graphite spring	5.00
Leaky radiator—off the car	3.75
Straighten front cross member	3.00
Overhaul steering gear	3.00
Change coil with Yale lock	3.00
Replace muffler	.50
Install running board bracket	2.50
Starting crank	1.25
Install engine pans	1.25
Tighten steering gear	1.25
Replace wheel (1) $ .60; (4)	1.25
Leaky radiator—on the car	1.00
Wheel, overhaul or change hub—each (cones and ball race)	1.00
Adjust clutch	.60
Starting crank ratchet pin	.60
Gasoline feed pipe or generator tube	.60
Tighten muffler or engine pan	.60
Install radiator or replace hose connection, each	.60
Tighten or replace fender or running board	.60
Dope car	.50

Body Division.

Repair—repaint and varnish car	$20.00
Refit curtains and recover top	10.00
Reupholster body (if new material used)	10.00
Change closed bodies	8.00
Change touring car or runabout body	5.00
Tighten all bolts	5.00
Change dash	5.00
Change bow on top, each	2.50
Install (1) windshield glass	1.25
Install (2) windshield glass	2.00
Refinishing deck on torpedo body	1.50
Tighten all doors	1.25
Tighten dash to body, or replace horn	1.25
Replace top iron, each	1.00
Holes in top	1.00
Replace windshield, tighten hinge screws or dash clips	.50
Replace celluloid lights, each	.60
Dent out of rear panel and refinish	10.00
Dent out of rear panel	8.00
Any side panel and refinish	6.00
Any side panel	4.00
Take dent out of door and refinish	3.00
Take dent out of door	2.00

Overhaul Model "T" touring car or runabout, including:
- Repainting car
- Repairing body, cushions and upholstering
- Top repaired or recovered
- Motor and transmission overhauled
- Rear system overhauled
- Front system overhauled 55.00

Of course, if the car is equipped with an electric starting and lighting device, or even with a mechanical starter, this may make the work of overhauling more difficult, and so the repair shop will be quite justified in making an extra charge for the extra labor involved. If the car is fitted with shock absorbers or other supplementary springs, this may make it more difficult to remove the rear axle and an extra charge is justifiable.

What Constitutes an Overhaul.

The customary labor charge for a complete overhaul of a Ford touring car or runabout is $55.00. This is for labor only, the cost of the parts installed being charged for extra and usually making the total charge about $75.00, for a complete overhauling. If the body of the car is not painted, an allowance of $5.00 for labor is usually deducted from this charge. The cost of the paint and varnish is included in the labor charge. **A complete overhauling should include:**

Removal of carbon from the engine, see chart 336 and pages 623 to 626.

Grinding the valves, if necessary, and adjusting valve tappet clearance, see charts 336 and 332, and pages 630 to 635.

Cleaning gasoline line, and the carburetor, see pages 162, 160.

Flushing radiator and water jackets of engine; see pages 191, chart 335.

Cleaning out old oil from crankcase, see page 201.

Cleaning differential housing and filling with grease, see page 772.

Clutch adjustment and relining transmission bands, see pages 776 and 777.

Adjustment of connecting rod and main bearings, see pages 786, 787, 641 and 646.

Fitting of pistons and rings, see pages 650, 657 to 659.

Adjusting, or replacing rear hub brake shoes, see page 781.

Tighten steering gear, and spring clips and small parts, see page 773.

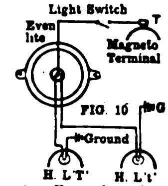
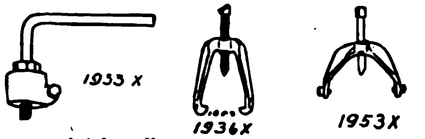
Valve grinding tools. VG2, VG3.	

**"St. Louis" Evenlite.

This device (fig. 10), controls the current from magneto and produces full candlepower of lights at 10 miles per hour and will afford a full, clear light at 6 or 7 miles with a very slight decrease from highest speed. Price complete, to go in dash under hood $4.00. To go on steering post, including a horn push button and switch on the device, so lights can be turned on, dimmed or cut off, price $6.00 Can be connected in 30 minutes.





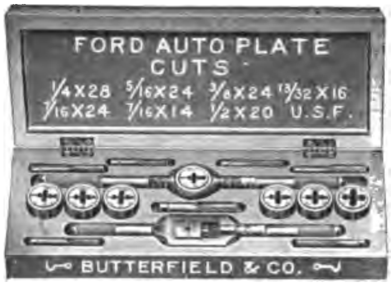
Ford Special Tools. Rear wheel puller assembly: old No. 1933X, new No. 3Z-612; **cam gear puller**; old No. 1936X, new No. 3Z-611; **transmission clutch puller**; old No. 1953X, new No. 3Z-614.

Cotter Pins for Ford Cars.
There are a total of 95 cotter pins used throughout the car, and 6 different sizes, as enumerated to the right.

5—3/32 x 1/2" No. 66.
38—3/32 x 5/8" No. 88.
27—3/32 x 3/4" No. 753.
4—3/32 x 1" No. 421.
11—1/16 x 1/2" No. 544.
15— 1/8 x 1" No. 82.

No. 4 — Combination wrench set: arranged for the Ford car but good for all cars.

Contains No. 511 ratchet wrench, 9"; extension bar, 9"; Universal joint; 8 pressed steel sockets. Sizes 17/32, 19/32, 21/32, 23/32, 25/32, 29/32, 31/32, and 1 5/32". Price $4.00.



****Butterfield screw** plate is designed for Ford Work, contains taps and dies, cutting all the threads for bolts and screws on the Ford. Made by Butterfield Co., at Derby Line, Vt. (See also, page 612).

Inspection After Repairing;
See to the Following:

1—Cylinder head tight.
2—All spark plugs firing, and tight.
3—Fan belt tight.
4—Fan bracket bolt and cotter pins tight.
5—Adjust carburetor properly.
6—Water connections tight and no leaks.
7—Hood properly fit.
8—Head lamps burn, properly focused, connections tight.
9—Front wheels adjusted, lubricated and lined up.
10—Fenders and running board bolts and nuts tight.
11—Doors work properly.
12—Emergency brake adjusted.
13—Trans. bands adjusted.
14—Floor boards fit properly.
15—Grease in rear axle.
16—Grease in all cups.
17—Oil in engine.
18—Water in radiator.
19—Tires properly inflated.
20—Examine tool kit.
21—Curtains fit.
22—Horn in working condition.

CHART NO. 341—Wrenches (Socket). Taps and Dies. Wheel and Gear Pullers. What Number Wrench to Use.

*See also page 613, and page 704, for taps and dies, "how to use."
**Can be secured of A. L. Dyke, Electric Dept., Granite Bldg., St. Louis, Mo.

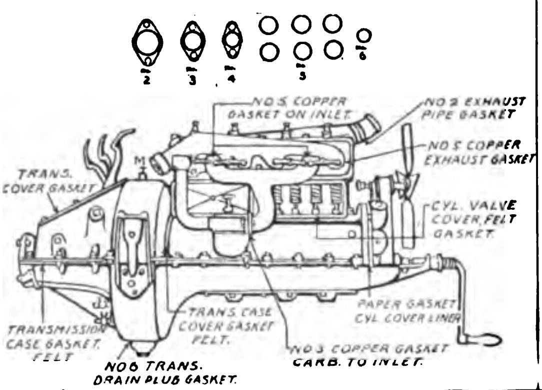


Fig. 74—Right side of Ford engine showing different location and kinds of gaskets used.

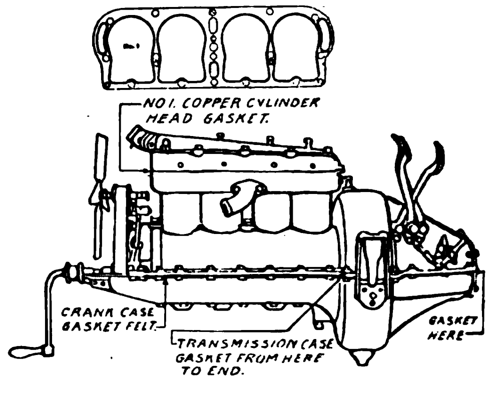

Fig. 75—Left side of Ford engine showing location and kinds of gaskets used.

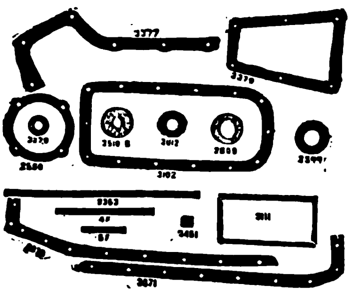

Fig. 76.

Gaskets.

H. 3102—Crank case lower cover gasket. 3111—Cyl. valve cover gasket. 3363—Trans. cover front gasket. 3377—Trans. cover gasket. 3379—Trans. sloping door gasket. 3451—Control bracket felt. 4-F—Trans. cover strip 7¾x½x 5/64 inch. 5-F—Crank case arm strip 8½x½x5/64 inch. 3544—Steering bracket. 2510B—For rear axle, 2 7/16x⅞x5/16 in. 2809—For front hub, 2⅛ in. diam. 3012—For cyl. cover, 2x 1 3/16x ⅝ in. 3279—For mag. contact, 1½x¾x5/64 inch.

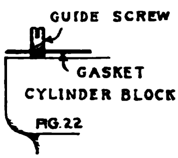

Fig. 78—Guide screws are handy for correct replacement of cylinder head gasket. They are made from cap screws with head cut off and slotted. Place one at front and rear diagonally opposite. Then place gasket over guide screws and replace cylinder head. Screws can then be removed.

Cylinder Head Gaskets.

There is a copper-asbestos gasket between the cylinder head and the cylinder block. There is practically no water pressure on this gasket, but there is a cylinder pressure, of from sixty pounds on the compression stroke to 250 pounds on the firing stroke, which must be withstood by the gasket. As the cylinder head bolts contract, when cool, and expand when hot,—there are varying degrees of pressure on the gasket, so the cylinder head must be securely seated to keep the cylinder head gasket from blowing out.

The gasket is composed of asbestos fabric, between sheets of brass and copper. (see page 717.) If examined closely, one end of the gasket will be found to have a different curve than the other. When the gasket is placed on the cylinder block, with its edges coinciding with the edges of the block,—the right side of the gasket will be turned upward, and no further trouble will be experienced.

Shellac, should not be used, on either side of the cylinder head gasket or on any of the other gaskets on the engine. If shellac is used, it will not be possible to remove the gasket without spoiling it. But, if grease is used, the grease will hold the gasket in place when the parts are being assembled, and it will cause no trouble when the engine is again taken apart. In this manner cylinder head gasket can be used several times.

The metal surfaces, between which any of the gaskets are clamped, should be clean and free from grit. A small lump of dirt will tend to cause a leak and spoil the gasket.

Asbestos can be substituted for head of cylinder if copper cannot be secured—sheet asbestos, size 1/16 thick x 7 x 20 inches.

Cylinder Head Cap Screws.

Cap screws are sometimes broken off when being tightened. Ordinarily, this involves the removal of the cylinder head and the attempt to drill out the broken part of the bolt. It is not easy to hold the drill perfectly true, so that the threads will not be damaged but by the use of the drill guide (G) furnished with the set, the drill can be held perfectly central, without the necessity of removing the cylinder head. Then the threads can be cleaned out with the 7/16 inch tap, and the new bolt installed. The cylinder bolts must be kept rather tight, or water is apt to escape around the cylinder head gasket. (see also page 709.

FIG. 71

If cylinder head cap screw threads becomes stripped, it is not advisable to drill a hole in head for an "oversize" screw, but drill cylinder block, tap and set in not less than a ⅝x18 thread blind plug, then drill and tap for standard cap screw (7/16x14.) 7/16 means the size of screw and 14 means the number of threads to the inch.

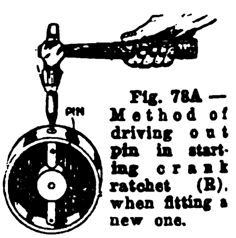

Fig. 78A — Method of driving out pin in starting crank ratchet (B), when fitting a new one.

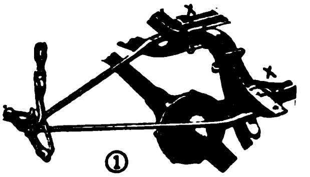
CHART NO. 342—Gaskets. Broken Cylinder Head Capscrews. Stripped Threads. Starting Crank Repair.

A broken fan belt can be temporarily laced with a violin (gut) string.

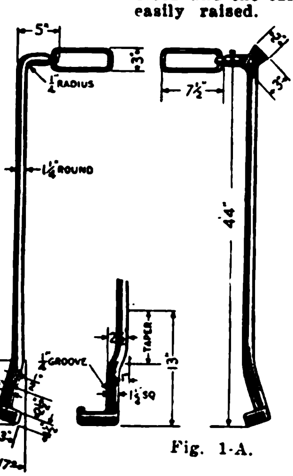
Device for Raising Rear End of Car.

Fig. 1 shows the hook in position for raising the rear end of car. By means of this device the rear end of the car can be held up securely while removing or repairing the rear axle assembly or spring. In attaching the hook place the clamps on end of each bar on the frame, then bring the ends of the bars together, one bar resting in the safety clevis on the other bar. The links are then placed in the hook on the chain block and the car easily raised.



①

Fig 1-A shows in detail with specifications the method of constructing the rear end hook. This equipment can be made by local blacksmiths and Ford agents will find it an efficient help in their repair work.



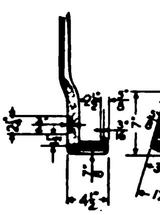


Fig. 1-A.

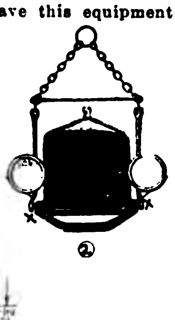
Device for Raising Front End of Car.

Fig. 2 shows device in position for raising the front end of a Ford car while removing or repairing front axle or spring. Each hook is placed on the fender iron below the nut on end of the lamp bracket. The ring is placed in the hook on the chain-block and the car easily raised.

Ford agents will be able to have this equipment made by local blacksmiths from the details and specifications shown in fig. 2-A. The front end hook should be part of the equipment of every Ford repair shop. (Ford Times.)



②

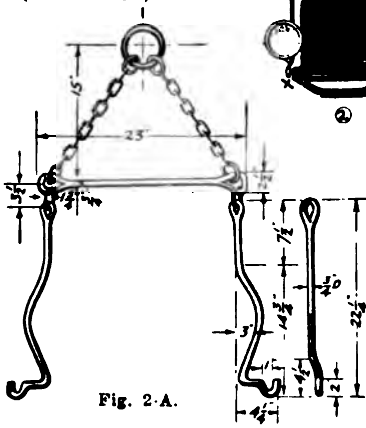


Fig. 2-A.

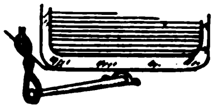

Fig. 79D — A twisted spring will keep the starting crank from rattling. A screen door spring is often used.

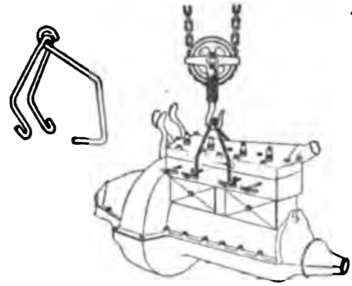

Fig. 79A—Engine lifting hook; used in conjunction with a chain block to remove the engine from the frame. It is in two parts, one U-shaped, and bent in the manner shown, having eyes to catch two manifold stud nuts, the other fastened to it, and bent to grab below the water jacket between the second and third cylinders. Ordinarily the manifolds, cylinder head, transmission case cover and crank-case base are removed, the illustration showing the application of the hook. When these are removed the engine will balance.

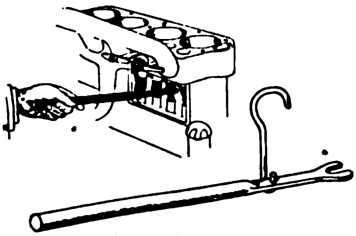

Fig. 79B—Tool for removing the valves may be made from a piece of steel ⅝ in. round and about 12 or 14 in. long. One end is flattened out for about 4 in. and then drilled ¼ in., and the flattened end is then notched in the manner shown to permit insertion beneath the valve locking washer. A piece of ¼ in. rod is then bent at both ends, one end passing through the ¼-inch hole in the lever and the other being used to hook over one of the manifold studs. By the aid of this lifter the valve may be removed without removing either manifold.

Towing in a Ford when the differential happens to lock or rear axle becomes defective—loosen hub caps, remove wheels and withdraw the keys in axle shafts. The wheels are replaced and car can be towed in with wheels turning free. Note—grease well before starting.

Auxiliary Wheel for Disabled Fords.

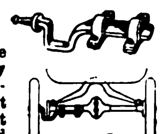

FIG 79 C

Ford cars disabled by having the rear axle broken near the hub may be towed in by the aid of the device shown. A bar of steel about 8 ft. long and 1½ in. square is put in the lathe and a standard Ford hub turned on one end and fitted with the cones and locking nut. The other end of the bar is then forged out flat and bent to clear the rear brake band, after which the lower clamping straps are riveted on. The addition of the upper clamping straps and a standard Ford wheel makes the outfit complete. To use, the disabled car is jacked up and the auxiliary wheel clamped in place, permitting the car to be towed in. In the case of a front wheel the procedure is much the same, except that the cross-steering rod must be tied and the car towed very slowly. The device is not limited to use on the Ford, and has been used to bring in a 1-ton truck.

Rear Axle Stand.

Fig. 79: Constructed of channel iron throughout, each upright laid out at a point of an L on the floor as shown. One-half of the rear axle housing passes through, and is held by two of these uprights, the other upright holding the torque tube. A steel cross-piece is riveted to this latter upright, serving as a rest for the radius rods.

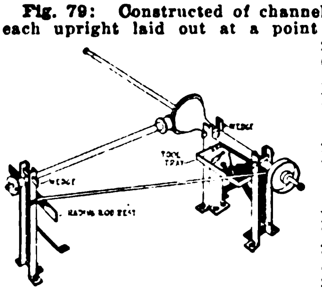

Fig. 80—The Kingston model "Y," see page 160 for a sectional view.

Carburetors.

Two types of carburetors are furnished on Ford cars:—the Holley, made by Holley Bros. Co., Detroit, Mich., and the Kingston, made by Byrne, Kingston & Co., Kokomo, Ind. There is very little difference in the adjusting of these two carburetors, but there is considerable difference in their repair, so they are here considered separately.

Dash Adjustment.

Both Holley and Kingston carburetors are of the automatic type, having but one adjustment,—the carburetor adjustment knob† is on the dash (fig. 81). Turning this knob to the right,—or in a clockwise direction—tends to give a weaker mixture and save gasoline. But, turning this knob to the left, opens the spray nozzle and gives a richer mixture, which makes starting easier. In fig. 81, the different positions are shown at A, B and C.

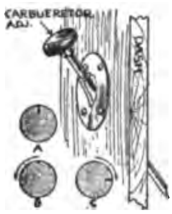

Fig. 81—Carburetor dash adjustment. A—is the position for correct mixture; B—for rich mixture; C—lean mixture. Adjustments in this direction saves gasoline.

Needle-valve Adjustment.

After the new car has been thoroughly worked in, a file mark or notch should be made on the face of this knob, so that the driver can determine the setting, even in the dark. (A) indicates the position at which the engine runs most satisfactorily. In cold weather, it will probably be necessary to turn the knob at least a quarter turn to the left, as at (B)—especially when starting.

As gasoline vaporizes more readily in warm weather, the driver will find it economical to reduce the quantity of gasoline in the mixture by turning the carburetor adjustment to the right (as far as possible without reducing speed) as indicated at (C). This is particularly true when taking long drives where conditions permit a fair rate of speed being maintained, and accounts for the excellent gasoline mileage obtained by good drivers.

Carburetor Adjustment.

The usual method of regulating the carburetor is to start the engine, advancing the throttle lever to about the sixth notch, with the spark retarded to about the fourth notch. The flow of gasoline should now be cut off by screwing the needle valve down (to the right) until the engine begins to misfire; then gradually increase the gasoline feed by opening the needle valve until the engine picks up and reaches its highest speed—and until no trace of black smoke comes from the exhaust. Having determined the point where the engine runs at its maximum speed, the needle valve binding screw should be tightened to prevent the adjustment being disturbed. For average running a lean mixture will give better results than a rich one.

***Starting the Engine in Cold Weather.**

The usual method of starting the engine when cold is to turn the carburetor dash adjustment one-quarter turn to the left in order to allow a richer mixture of gasoline to be drawn into the cylinders; then hold out the priming rod, which projects through the radiator, while you turn crank from six to eight one-quarter turns in quick succession.

Another method of starting a troublesome cold engine is as follows: Before you throw on the magneto switch, (1) close throttle;** (2) hold out priming rod while you give crank several quick turns, then let go of priming rod (being careful that it goes back all the way); (3) place spark lever in about third notch and advance throttle lever several notches; (4) throw on switch (being sure to get it on side marked "Magneto"); (5) give crank one or two turns, and engine should start. After engine starts it is advisable to advance the spark eight or ten notches on the quadrant and let it run until thoroughly heated up. If you start out with a cold engine you will not have much power and are liable to "stall." The advantage of turning on the switch last, or after priming, is that when you throw on the switch and give the crank one-quarter turn, you have plenty of gas in the cylinders to keep the engine running, thereby eliminating the trouble of the engine starting and stopping. After engine is warmed up turn carburetor adjustment back one-quarter turn.

To Facilitate Easy Starting.

Some drivers make a practice of speeding up the engine by opening the throttle, just before stopping (by turning off the coil switch). This leaves the cylinders fully charged with gas. See bottom of page 158, left column.

Pulling out the priming ring, and thus causing a very rich mixture to be drawn into the cylinders, is another method of stopping the engine that will make it easier to start in cold weather. If tried in warm weather, it is apt to leave such a rich mixture in the cylinders that the engine will be hard to start within the next hour or two. Explanation of "Rich and Lean Mixtures" is given on pages 168 and 169. (Also, see page 489, on starting engine with the switch open.)

Kingston carburetor is shown in sectional view on page 160. This shows how the gasoline enters the carburetor, is vaporized in a current of air, and then passes through the inlet manifold to the engine in the form of an explosive mixture, which gives the power.

The hot air pipe, from the air intake of the carburetor to the exhaust manifold, is useful in summer as well as winter with poor gasoline (see page 155).

Float Level Adjustment of Kingston.

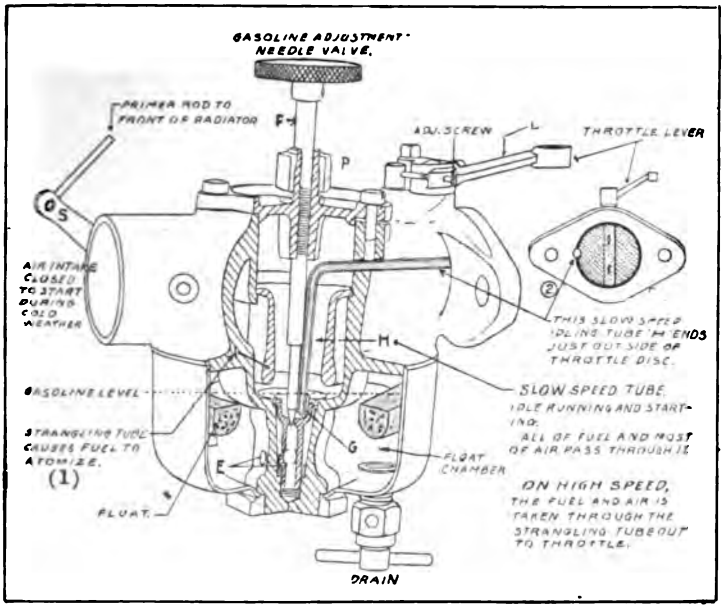
Model Y Kingston, used on 1913-14 Ford cars. Float should be set to show a clearance of 9⁄32 inch from top of the float to the top or face of the cup casting. (model L, 1915 and early 1916, same.)

Model L-2 (1916-1918): The action and the float setting of this carburetor is entirely different from that of the other two models. The float is hinged directly to the body, instead of in the cup, as in models Y and L. To test the level of the float, turn the body upside down and when properly set, it should show a clearance of 1⁄16 inch from the machined surface on the top casting to the top of the float, at a point directly opposite the point where the float is fastened to the body of the carburetor. (see chart 345 for level of float of Holley).

CHART NO. 344—Carburetor Adjustments—Kingston. The same needle valve or dash adjustment applies to Holley also.

†It is now a bent wire rod. *See also pages 170, 489, 153, 161 and 155.

**Throttle is never entirely closed. (see "throttle adjusting screw A," chart 345).



Holley Model "G" Carburetor.

From the float chamber the gasoline passes through the ports (E) to the nozzle orifice in which is located the pointed end of the needle (F).

A drain valve is provided for the purpose of drawing off whatever sediment or water may accumulate in the float chamber.

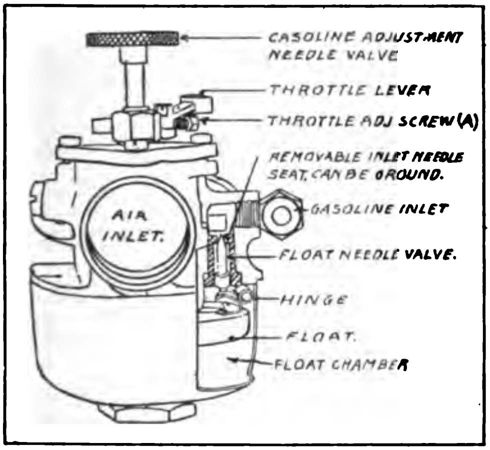
The float level is so set that the gasoline rises past the needle valve (F) and sufficiently fills the cup (G) to submerge the lower end of the small copper tube (H). Drilled passages in the casting communicate the upper end of this tube with an outlet at the edge of the throttle disk. (see 2.)

The tube and passage give the starting and idling.

The strangling tube (1) gives the entering air stream an annular converging form, in which the lowest pressure and highest velocity occur immediately above the cup (G); thus it is seen that the fuel issuing past the needle valve (F) is immediately picked up by the main air stream, at the point of the latter's highest velocity. Termed the venturi principle.

This gives thorough atomization of the fuel and results in very economical and powerful performance. The lever (L) operates the throttle.

For facilitating starting in extremely cold weather. A disk attached to lever S, with spring return, is connected to a priming rod. By closing this, an excess of gasoline is drawn into cylinders.



Holley Carburetor Needle Valve Troubles and Remedies.

Carburetors may leak from following causes:

(1) Sediment in fuel lodging on the needle valve seat, preventing needle from closing.

(2) Inlet needle or seat damaged or worn.

(3) Fuel level too high, flooding the nozzle.

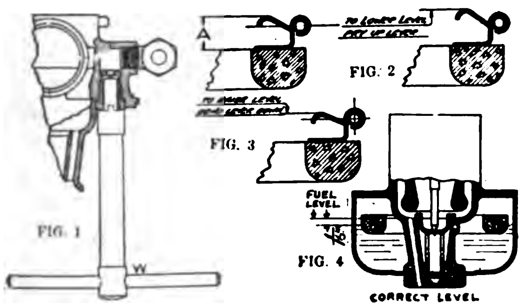
These troubles may be overcome as follows:

(1) Thoroughly clean the fuel tank, pipe and carburetor, removing all sediment. After cleaning fuel system filter fuel through a clean piece of chamois.

(2) **Damaged float inlet needle:** Inlet needle and seat should be replaced if a ridge is worn on the tapered point, or if seat is scored; but in no case should a needle be replaced without a new seat, or vise versa.

To remove detachable seat, unscrew float chamber nut at bottom of carburetor, take off float chamber containing float and lever and inlet needle, then insert socket wrench as shown in fig. 1.

When installing new seat do not turn it up too tight, as this may leave a burr inside which will interfere with the movement of the needle. After installing the seat and new needle see that the latter works freely before attaching the float.



Adjusting of Fuel or Float Level.

Attach carburetor to manifold and then take off mixing chamber cap by taking out screws. This will enable you to see the nozzle and fuel level. Connect the fuel line to the carburetor; turn on fuel; note where level comes. The level should be as shown in fig. 4.

Level too high, flooding the nozzle: Remove the float chamber and pry up the lever, as shown on fig. 2, until the level is correct. The gasoline level should be from 1/16" to 1/8" lower than the top of the nozzle—fig. 4.

Fuel level too low: Should the level be lower than shown in fig. 4, bend the tab on float lever (that the needle rides on), down toward the float, as shown on fig. 3. It is best to detach float and lever for this operation, by drawing out float lever pin. The distance from machined flange on the mixing chamber, to the top of float lever should be about 1/8" when float valve is closed.

Caution: It requires a bend of only 1/32 of an inch on the float lever in order to change the gasoline level 1/8 of an inch. When setting float, try to keep it at an angle, that is, the part opposite the float lever—so the pressure of the gasoline will assure a tight fit.

CHART NO. 345—Holley Carburetor also Used by the Ford Co.

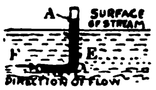
The Holley Co. (Detroit), also manufacture a Ford carburetor suitable for kerosene. See also page 160.

The Schebler Plain Tube Carburetor With Pitot Tube Principle.

This model is known as the "model Ford A" and differs from the average carburetor. It is a similar principle as shown on pages 176 and 177. Such moving parts as dash pots, metering pins for increasing the flow of gasoline has been eliminated—yet a rich mixture for acceleration can be obtained quickly.

Explanation of a Pitot Tube.

A Pitot tube is a very old instrument for measuring velocities of flowing streams of water. Invented by Henri Pitot in 1730. It consisted of a vertical glass tube with a right angled bend as shown at (E).



The impact of the flowing water against open end (F) of tube (E) caused a column to rise above the surface of the stream as at (A), and by this small difference in height, the velocity of the stream was calculated. A similar principle, but to provide air is embodied in the carburetor to be explained.

Schebler Plain Tube Carburetor.

Adjustments; there are two gasoline adjustments, one for low speed 4 to 5 m. p. h. up to the maximum without "loading" up or missing.

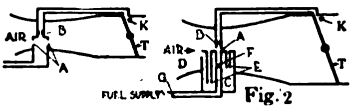


Fig. 2

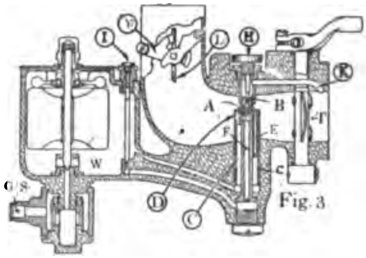

I—high speed gasoline adjusting needle.
H—low speed gasoline adj. needle.
L—choker valve. T—throttle valve.
K—idle and low speed by pass.
D—Pitot opening.

Operation or Action.

The theory of operation is that gasoline and air obey the same laws of flow, therefore, if they are started at a common zero, the flow of fuel out of a nozzle inserted in and caused by a flow of air through a pipe or in a carburetor, a venturi will remain directly proportional. However, fuel in the liquid state does not flow until considerable head is produced, due to surface tension or capillarity. To break this tension, or holding, of the fuel in the jet, the high vacuum above the throttle is utilized.

Air flows into and through the choke or venturi tube in the direction of the arrow (fig. 2) but for idle speeds of the engine the velocity is too low to cause suction enough to break the surface tension at the main nozzle (A). An extension (K) is provided from the main nozzle to the space above or engine side of the throttle (T). The size of this extension or passage is controlled at (B) by screw (H).

In operation the high suction above the throttle (T) breaks the surface tension in the main nozzle and causes fuel to flow through the extension (K) with some air which is drawn in through the main nozzle holes (A) at (B by H), the flow rate can be made to equal that which would be taken out of (A) if surface tension were eliminated. As the throttle is opened the increasing suction at the main nozzle cuts down the air bleed through the holes (A) and causes more fuel to pass through the extension (K) until that suction caused by the flow of air at main nozzle (A) equals the decreasing static suction above the throttle (T). Then fuel comes out of the main nozzle holes (A) into the main air stream. This also probably causes a slight reversal flow in the extension passage.

This combination produces a correct proportion of air and fuel through a very large range if the throttle is not thrown wide open from its closed position suddenly. When this happens the engine would lay down or miss six or seven shots and sometimes die completely.

To overcome this trouble an overflow well, or reserve chamber (C), is formed around the main fuel passage, whose top is integral with the main nozzle head and provided with a downstream pitot (D). From this head two acceleration tubes (E) extend to different depths into the overflow well (C) and discharge into the main air stream.

Pitot Supplies Air.

With the engine idling or running slowly the well (C) will fill up by means of the hole (F) in the main nozzle passage.

Upon suddenly throwing the throttle wide open the reserve supply of fuel is taken out the acceleration tubes (E) as well as from the main jet (A). This practically makes a temporarily large jet or nozzle until one of the tubes (E), is uncovered by the lowering of the fuel level in the well. Air then is drawn out through this tube and acts in opposition to the supply of air from the pitot (D). This opposition causes a gradually increasing suction in the well (C) and uniformly decreases the discharge of fuel therefrom out of the longer tube (E). This operation fills in the time element necessary for the main jet to resume its normal functions of delivering a thin mixture.

The tubes (E) also are made of varying lengths to hold a reserve supply of fuel in the well from some intermediate speed of, say, 15 m.p.h.

The pitot function is simply to provide air at sufficient pressure to force the fuel from the well and be inclosed in the carburetor. It so happens that in a stream of air the pressure head due to velocity is negative and exactly equal to the positive impact head due to the same velocity, therefore, the pitot hole, facing down stream, delivers air to the well at or very near atmospheric pressure.

All the fuel passes through the main adjustment (G), which is located at the float bowl and governed by screw (I), therefore, controls the whole range of the carburetor while still allowing the idle or low-speed adjustment to be changed with the condition of the engine or variations in engines of the same design.

Gasoline float level is 1 in. below top of bowl with needle seated.

Engine Troubles.

Engine fails to start; (1) lack of gasoline—see page 798; (2) no spark—see page 808. Additional reasons may be dirty magneto terminal, vibrators not adjusted properly. See pages 234 and 578 to 581.

Engine loses power; see pages 790, 626, 628 for poor compression; mixture not correct, see pages 169 to 171; valves need grinding; valve clearance not correct; **engine stops**—see page 578.

***Engine overheats**—see page 579 and 189. **Engine knocks**—see page 790, 635 to 639 and 580.

Engine misses explosion—see pages 579, 808, 234 to 236 and 169 to 171.

Popping in carburetor—lack of gasoline (see page 170); **black smoke**, too much gasoline; **blue or white smoke**, too much lubricating oil; **grey smoke**, excess of both—see page 169.

CHART NO. 346—Principle of a Plain Tube Carburetor with Pitot Principle Introduced.

A gas heated inlet manifold will save gasoline and assist carburetion—see pages 160 and 155.

*To thaw out a frozen radiator—see pages 788, 579, 193.

*Auxiliary Air Valves.

The high cost of gasoline and the low cost of air has made many owners of cars wish that they could burn air instead of gasoline. While this is, of course impossible, it is still quite true that a much greater mileage per gallon of gasoline can often be obtained by burning the gasoline vapor more completely in the presence of additional air.

Complete combustion occurs when there is sufficient air mixed with the fuel to furnish enough oxygen to combine with all the fuel particles. When complete combustion is obtained, no smoke or carbon will be formed. Thus the use of auxiliary air valves may reduce the amount of carbon deposited in the cylinders.

The mixture of gasoline and air as it comes from the carburetor is often full of little drops of almost pure gasoline. These drops are simply burned in the cylinder, instead of forming an explosive mixture, as they would if the mixture were more perfectly vaporized. The admission of air into the side of the stream of gasoline vapor often serves to form whirlpools which churn the gasoline particles into a more perfect mixture with the air.

If your carburetor mixture is perfect then the air valve is unnecessary. Unfortunately most carburetors are far from perfect and the air valve under the control of the driver compensates for carburetor deficiencies. The air valve, in most instances increases the efficiency of any carburetor, if properly applied.

To determine if the auxiliary air valve is required, close the throttle and retard the spark until the engine runs as slowly as possible. Then adjust the carburetor until the engine runs smoothly and evenly on the least possible amount of gasoline.

Now take the car out on the road and, with the spark advanced and the car traveling at about twenty or twenty-five m. p. h., attempt to reduce the amount of gasoline by turning the carburetor dash adjusting knob.

If the amount of gasoline can be reduced without greatly affecting the power and speed of the engine, the fitting of an auxiliary air valve will be advantageous.

Types of Air Valves.

The type of air valve fitted should be one that supplies additional air at high speeds. But if, on the contrary, the engine requires a richer mixture at high speeds, when the carburetor is adjusted for good running at low speeds, then that type of air valve should be fitted that supplies air at low speeds, but is drawn closed by the suction at high speeds.

Correct adaption of the air valve to eccentricities of the particular engine and carburetor are necessary to get good results.

To obtain the best results from the auxiliary air valve, it should be easily controlled, preferably from the steering column. If it is operated from the dash, it will be little better than the carburetor adjusting knob which is already provided. In fact, the idea of the air valve is to bring the carburetor more completely under the control of the driver.

Fig. 1—Perhaps the simplest form of auxiliary air valve is that made by threading a Ford oil cup into a hole in the side of the intake manifold. A strip of brass about half an inch wide should be soldered to one side of the movable part of the oil cup, thus forming a lever by means of which the opening and closing of the air valve may be controlled. A hole may be drilled near the end of this lever, and a wire connected to the lever, this wire running through copper tubing or a *Bowden wire arrangement to the steering column. The end of the wire may end in a loop or be connected to a small lever to suit the convenience of the driver.

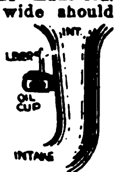

FIG-1 AUXILIARY AIR VALVE

*Bowden wire is small, flexible, metallic tubing, with a strong but flexible wire running through it, (see T—page 173, fig. 3.) Can be obtained from motorcycle agents, as it is used on the control system of many motorcycles.

Fig. 3—Another simple form of air valve, which is more nearly airtight when closed, consists of a priming valve, screwed into an elbow attached to the intake manifold. A hole can be drilled through the handle of this priming valve for the attachment of the wire to the steering column control.

This air valve has the advantage that it can be used for priming in cold weather, or for introducing water or kerosene for loosening carbon deposits.

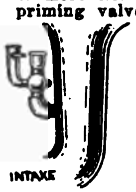

FIG.3-PRIMING VALVE

In winter, it is preferable to inject warm, rather than cold air into the manifold, and for this purpose it is often well to fit a soft copper pipe, (which can be wrapped around the exhaust pipe) to the air valve.

Fig. 2—An air valve made of standard quarter-inch pipe fittings and valve is also shown, and the end of the intake pipe is covered with a sheet iron sleeve, so that hot air will be drawn from the top of the exhaust manifold.

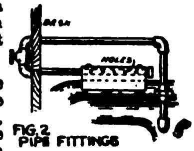

FIG.2 PIPE FITTINGS

Another form of air valve: which eliminates the use of moving parts, is as follows: One end of a copper tube is fastened by means of a brass coupling to a hole in the side of the intake manifold. The tube is then given four turns around the exhaust manifold near the point where the exhaust pipe is connected. The copper tubing is then led along the dash and up the steering column, ending in an air valve directly under the steering wheel. Of course, this device can be used for priming the motor or injecting carbon softening solutions.

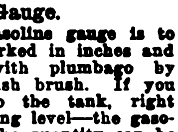
When first installed, this device made a whistling sound when the air valve was opened, but this was overcome by rounding off the edges of the air valve, and since then has given entire satisfaction.

The auxiliary air valve is most useful in hilly country, for then conditions vary most widely. It is possible to use the air valve to make the engine act as a brake when coasting down hill. The admission of the air tends to cool the engine, so that the next hill will be climbed more easily. Opening the air valve also breaks the suction in the cylinders and keeps the oil from being drawn up and fouling the spark plugs when the engine is used as a brake on long hills.

A Primer.

For extreme cold weather a method of priming is shown. Take off inlet pipe and drill hole for ¼ inch pipe tap and fit a priming cock.

To operate, (1)—turn off switch, (2)—pour about a table spoonful of gasoline into intake through this cock. Keep an oil can filled for the purpose. (3)—close up cock, (4)—crank three or four times with switch off. 5—now turn on switch, open throttle and engine will start—see also page 156.



See also foot note bottom of page 153, (see page 735 for "super-heated" steam for carbon removal and page 823).

*Gasoline Tank Gauge.

A good idea for a simple gasoline gauge is to get a cheap 18 in. flat rule, marked in inches and fractions thereof. Coat it with plumbago by applying the domestic stove-polish brush. If you insert this rule vertically into the tank, right down to the bottom—the car being level—the gasoline will leave a mark on it. The quantity can be gauged as per marks on the rule as follows:

1 gal.	......1 11/32 ins.	6 gal.	......5 29/32 ins.
2 gal.	...... 2 9/16 ins.	7 gal.	...... 6 3/4 ins.
3 gal.	...... 3 1/2 ins.	8 gal.	......7 11/16 ins.
4 gal.	......4 11/32 ins.	9 gal.	......8 23/32 ins.
5 gal.	...... 5 1/8 ins.	10 gal.	......10 1/4 ins.

*See also page 823.

CHART NO. 347—Auxiliary Air Valves. Priming Methods. Gasoline Tank Gauge

Exhaust heated inlet manifolds are recommended—see page 155. A Ford gasoline-kerosene carburetor is illustrated on page 160. Air valves above from "Fordowner." *A recommended type of air valve is shown on page 785, fig. 12.

Control of Carburetor Mixture.

A saving in gasoline: All Ford users are acquainted with the peculiarity of the Ford carburetor, in which variation of the strength of the mixture is obtained by altering the size of the jet, the alteration being effected by screwing a vertical needle up or down. This needle is tapered at its lower end, and the tapered portion enters the jet orifice; consequently, as the needle is lowered the jet is closed; as the needle is lifted, the jet is opened and the size of the hole increased. This alteration is controlled by the driver through the medium of a rod which projects through the dash, per chart 344, the top end of the rod is fitted with a suitable device, for convenience when handling; the lower end is forked as per (D), page 160, and the two prongs of the fork fit into suitable holes in a disc on the top of the needle already mentioned.

If you are a motor-wise driver, you set that disc differently for varying conditions, turning it anti-clockwise for starting, clockwise when you have started, and still further clockwise when you have been running for, say 15 minutes. As the cool of the evening comes on, you will probably find it advantageous to turn the disc back again a little. In other words, you keep the disc as nearly as possible for maximum efficiency of the mixture under all conditions.

***The jet should be opened slightly so that sufficient gasoline is available for fast running,** while at the same time the mixture is too rich when running slow.

On the other hand, as the spark is advanced, the jet should be slightly closed and mixture weakened.

The increase of fuel for an increased throttle opening is not much; it is just sufficient to allow of the correct proportions of gasoline and air being provided when the engine is demanding its full supply of gas. It is a known fact that a weak mixture can be readily fired by a spark when fully advanced. The result is, an economy of fuel.

The conditions are always varying, and you cannot always be bending forward to twiddle that disc, and if you could your adjustment would not be fine enough, and it means fine adjustment to keep the mixture just right. If it is not just right, you will be simply wasting gasoline instead of using it economically as an ingredient in an efficient explosive mixture.

This device provides an accessible control which will enable you to set the disc anew whenever conditions indicate the need, and to set it to a really fine point of adjustment, so that the mixture will not be in the nature of a compromise.

A method employed (by an experimenter who is fond of tinkering), is similar to devices used on some of the other makes of carburetors and is nothing more than a **hand control** placed on the steering post as per fig. 82.

A steering column control as per fig. 5, page 173 is utilized, together with wire and casing (T), explained on the same page. A small lever is riveted and soldered to the carburetor dash control adjustment.

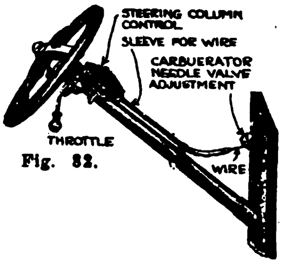


Fig. 82.

The fitting of the parts should be careful and accurate, so that there will not be the slightest play or lost motion.

If this device is used in conjunction with the throttle, as explained above, it is claimed that a saving of gasoline will be obtained, together with a cooler and smoother running engine. There are suitable graduations for different driving conditions, which the driver will soon learn, and the mixture can be made richer or weaker as required by the road driving conditions. Do not trouble, however, to experiment with this device unless you are a "fine point" driver as it will be of little assistance unless you study out the principle and know when and how to regulate the adjustment.

†More Miles Per Gallon.

There are three ways of obtaining more miles per gallon: (1) by increasing the efficiency of the engine; (2) by reducing engine and running gear friction; (3) and last, but not least, by skillful driving.

The efficiency of the engine can be increased by careful carburetor adjustment, which must be changed frequently, if the best possible results are to be obtained. Worn carburetor parts waste gasoline and should be replaced. Either an attachment for leading hot air to the carburetor, or a special manifold, which heats the vapor mixture after it leaves the carburetor, should be used to ensure complete vaporization of the fuel and give higher efficiency.

Carbon cuts down the efficiency of the engine and should be removed occasionally. Poor oil tends to form carbon, so good oil should be used, as it also causes less friction and wear.

Loss of compression, due to leaky piston rings or leaky valves will cause a steady loss of power, which must be compensated for by opening the throttle wider, thus wasting gasoline. Scored or worn cylinders will have the same effect. And the valve tappets should be adjusted, to provide the proper clearance as given on pages 94, 85 and 110.

Idling or running the engine while the car is at rest, or racing the engine unnecessarily, tends to waste fuel.

Good ignition is another essential in making the most out of the fuel. Driving with a retarded spark tends to waste the power of the engine and causes overheating also.

Gasoline leaks from the tank, pipe line, or carburetor sometimes waste considerable gasoline and, as the fuel evaporates as fast as it drips, this loss of fuel is not always quickly noticed.

The most economical driving speed is about 20 miles per hour.

CHART NO. 348—More Miles Per Gallon. Fine Point Carburetor Adjusmtent.

†See also page 819.
*See page 798.
See page 809 for ether and gasoline.

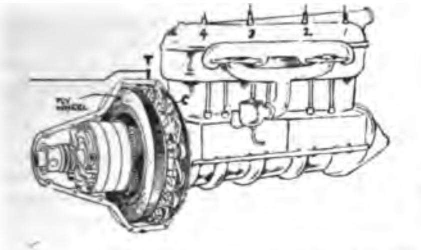

Fig. 86—An exaggerated line drawing showing the magneto location. Note coils (C) which are stationary and the magnets (A) which rotate. When fly wheel revolves, the 16 magnets (see fig. 91, chart 351) revolve in front of the 16 coils.

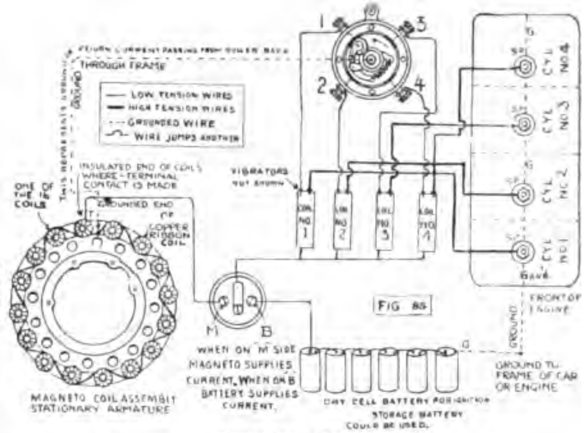

Ignition Circuit.

Wiring diagram showing path of primary and secondary circuits is shown in fig. 85. Although dry cells are shown connected, they are not supplied as regular equipment. The magneto alone supplies current for ignition, lights and horn as per fig. 87-A. Storage batteries could be used instead of dry cells and connected in place of same on the (B) side of switch (see (B) rear of coil box, fig. 87 where to connect one terminal of battery if used.) The other terminal is grounded. If storage battery is only 6 volts, (which is the usual voltage,) then it could be used only for ignition. To use for lights ignition and horn it would be necessary to either use a 9 volt battery or use 6 volt lamps. Ford cars are fitted with 9 volt lamps as regular equipment.

Primary Circuit.

When switch is on (M) or magneto side, the current would be supplied by magneto. The current travels from magneto terminal (T) to switch thence through primary winding of coil to insulated terminal post (1, 2, 3 or 4) on commutator, thence through metal part of roller through ground or metal part of engine, back to grounded end of magneto coil. The commutator makes contact with **one of the 4 insulated posts or contacts as the roller revolves.**

Secondary Circuit.

The current is intensified in the secondary winding of coil and travels from coil unit 1, 2, 3 or 4 in which the commutator makes contact, to the spark plug (SP.) Note heavy lines, indicating high tension current. (see pages 226 and 220 for principle.)

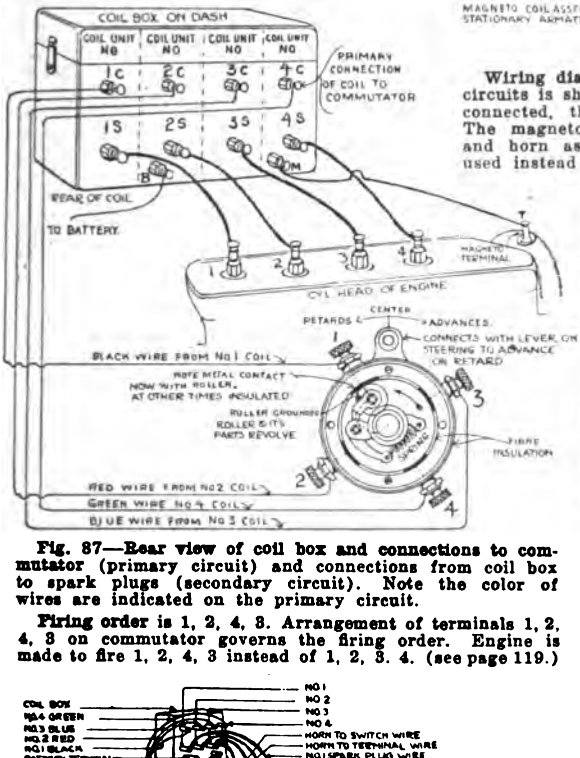

Fig. 87—Rear view of coil box and connections to commutator (primary circuit) and connections from coil box to spark plugs (secondary circuit). Note the color of wires are indicated on the primary circuit.

Firing order is 1, 2, 4, 3. Arrangement of terminals 1, 2, 4, 3 on commutator governs the firing order. Engine is made to fire 1, 2, 4, 3 instead of 1, 2, 3, 4. (see page 119.)

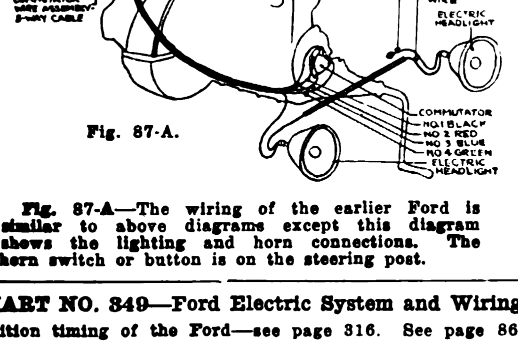

Fig. 87-A.

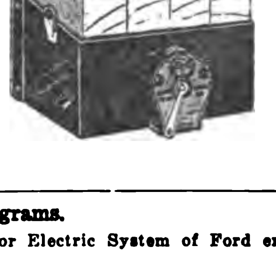
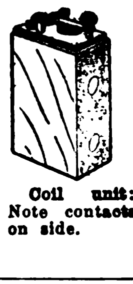
Fig. 87-A—The wiring of the earlier Ford is similar to above diagrams except this diagram shows the lighting and horn connections. The horn switch or button is on the steering post.

The Coil Box.

Fig. 88—The coil box contains 4 high tension (vibrator type) coil units. The units can be removed from the box in case one is damaged. Connections to coils are shown in figs. 87 and 87-A.





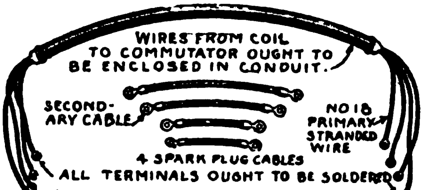
Coil unit: Note contacts on side.

CHART NO. 349—Ford Electric System and Wiring Diagrams.

Ignition timing of the Ford—see page 316. See page 864-A for Electric System of Ford enclosed cars.

Size of Wires.

The wires running from the secondary or high tension connections of the coils to the spark plugs are called secondary cable wires. Cable to No. 1 plug is 15 inches long. No. 2 cable is 11½ inches long. No. 4 cable is 8 inches long. No. 3 cable is 8 inches long.



A FORD IGNITION SET OF WIRES

**The size of wire running to the commutator, is No. 18 B and S gauge (stranded wire, see page 240).

If the latter wires are run in non-metallic conduit or circular loom (see page 241) the liability of short circuits and oil soaked wires will be greatly lessened. There are now 5 wires; one for light.

All wires ought to have terminals soldered on to the ends and all connections made as explained on page 240 and 427.

Dry Cells for Starting.

(B) side of switch can be used for batteries (dry or storage) for starting and after starting the switch is placed on (M) or magneto side (see fig. 85.) The Ford Co. claim however, the magneto gives current at a very low speed and batteries are not necessary. (If dry cells are used, use 5 or 6.)

Storage Battery for Ignition and Lights.

Can be connected in place of dry cells as shown in fig. 85. (also see chart 358.)

In connecting a storage battery the battery terminal should never be connected to the magneto terminal post on dash, as this will demagnetize the magnets.

To Set the Time of Spark.

See page 316. Note the No. 1 piston is placed ⅛ inch down after top of compression stroke, and roller on commutator is just starting to make contact with No. 1 cylinder. The commutator housing is retarded.

*Commutator Troubles.

If misfiring occurs when running at high speed, inspect the commutator. The surface of the circle around which roller travels should be clean and smooth, so that the roller makes a perfect contact at all points. If the roller fails to make a good contact on any one of the four contact points, its corresponding cylinder will not fire. In case the fibre, contact points and roller of the commutator are badly worn, the most satisfactory remedy is to replace them with new parts, or probably the trouble is caused by short-circuited commutator wires. The **spring should be** strong enough to make a firm contact between the roller and contact points even though slightly worn or dirty. (see fig. 13, page 241.)

Other causes of misfiring may also be due to an improperly seated valve, or short circuit in the commutator wiring.

Weakness in the valves may be easily determined by lifting the starting crank slowly the length of the stroke of each cylinder in turn, a strong or weak compression in any particular valve being easily detected. It sometimes happens that the cylinder head gasket (packing) becomes leaky—permitting the gas under compression to escape, a condition that can be detected by running a little lubricating oil around the edge of the gasket and noticing whether bubbles appear or not. Another source of leakage is around spark plugs. Test same way (see page 232).

How a short circuit in commutator wiring may be detected: Should the insulation of the primary wires (running from coil to commutator) become worn to such an extent that the copper wire is exposed—the current will leak out (i. e., short circuit) whenever contact with the engine pan or other metal parts is made. A steady buzzing of one of the coil units will indicate a "short" in the wiring. When driving the car the engine will suddenly lag and pound on account of the premature explosion. **Be careful not to crank the engine downward against compression when the car is in this condition,** as the "short" is apt to cause a kick-back.

Parts of commutator which are most apt to get out of order are; the roller, the spring, or the fiber lining and contacts in the commutator shell. (see fig. 89, chart 349).

Cold weather effect on commutator: It is a well known fact that in cold weather even the best grades of lubricating oil are apt to congeal to some extent. If this occurs in the commutator it is very apt to prevent the roller from making perfect contact with the contact points imbedded in the fibre. This makes difficult starting, as the roller arm spring is not stiff enough to brush away the film of oil. To overcome this, as well as any liability of the contact points to rust, we recommend a mixture of 25% kerosene with the commutator lubricating oil, which will thin it sufficiently to prevent congealing, or freezing, as it is commonly called. You have probably noticed in starting your car in cold weather that perhaps only one or two cylinders will fire for the first minute or so, which indicates that the timer is in the condition described above and as a consequence a perfect contact is not being made on each of the four terminals.

Removing Commutator.

Remove cotter pin from spark rod and detach latter from commutator. Loosen the cap screw which goes through breather pipe on top of time gear cover. This will release the spring which holds the commutator case in place and this part can be removed. Unscrew lock nut; withdraw steel brush cap and drive out the retaining pin. The brush can then be removed from the cam shaft.

In replacing the brush: reinstate so that the exhaust valve on the first cylinder is closed when the brush points upward. This may be ascertained by removing valve door and observing operation of No. 1 valve.

The commutator is to set 2½" from the center of the commutator case spring cap screw to the center of the commutator case pull rod when the spark lever is fully retarded (up as far as it will go). The case should be set by the spark lever on the steering column to take up any lost motion. The adjustment is made by turning the rod in or out of the ball socket joint. If this adjustment is inadequate, bend the pull rod.

CHART NO. 350—Commutator Troubles. Size and Colors of Wire. Dry Cells and Storage Battery Connections. Setting the Time of Spark

*See fig. 89, page 805 for commutator construction. **See page 803 color of wires.

The Commutator

Is similar to the type explained on pages 225 and 222, fig. 2. It is placed on the end of the cam shaft, that is, the roller mechanism is attached to end of cam shaft and revolves with it, there-

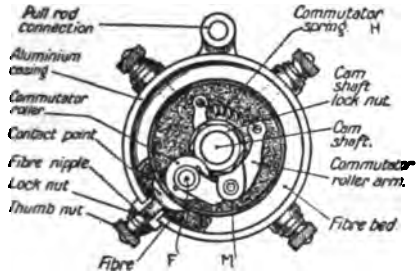


Fig. 89. The commutator.

fore the roller revolves ½ the speed or revolutions of the crank shaft. The roller makes contact with the insulated contact points of which there are 4 and which do not revolve. When roller comes in contact with one of the 4 insulated contact points, the coil unit connected with it becomes operative. As roller leaves contact, coil becomes inoperative.

To advance or retard time of spark, the housing is connected at "pull rod connection" with spark lever on steering wheel. See fig. 87 and note position to move to advance or retard. See page 222.

The Magneto

Supplies current for ignition, lights and horn as per fig. 87A. It is different from the usual type magneto.

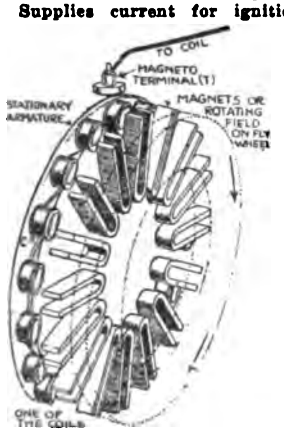

Fig. 91. Note the 16 magnets which revolve directly in front of the coils, also see page 265.

Magnets: instead of the horse shoe magnets being placed over the pole pieces and armature revolving therein note the position of magnets and coils in fig. 91. The magnets are called the rotating field.

The armature in this instance is stationary and consists of 16 coils* of thin copper tape wrapped over soft iron cores.

The consecutive coils are wound in opposite directions and are connected in series (see fig. 90.) The first coil terminal (to the left) in fig. 90, is connected to magneto terminal. The end of the 16th coil is grounded to iron frame which supports them.

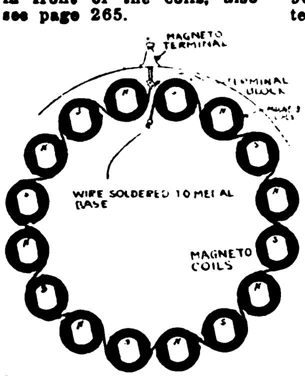

Fig. 90. The armature which is stationary.

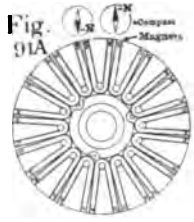
The current generated is low tension, alternating, as explained on page 265. This low tension current is transformed to a high tension current through coils, fig. 88.

**Voltage varies from 8 volts, lowest speed, to 25 or 30 volts at highest speed. Normal being about 18 to 20 volts at average speed.



†Fig. 91A. The magnet poles of magneto are placed with like poles together and are mounted on fly-wheel. To test: S pole of magnet will attract N pole of compass needle and N pole of magnet will attract S pole of compass needle.

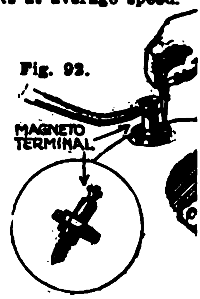


Fig. 92. Dirt on the magneto terminal contact will cause dim lights and misfiring. It can be removed and cleaned.

**Cause of Weak Magnets.

(1) Dirty contact as per fig. 92.

(2) End play in bearings, caused by worn crank shaft bearing will permit magnets to rotate at too far a distance and current will be weak.

(3) A grounded magneto coil will weaken current.

‡Testing for Grounds.

In magneto coils; connect 5 or 6 dry cells to a 6 volt lamp (fig. 93). Attach one end of terminal from lamp to magneto terminal. (T). Then unsolder the grounded end of winding at coil C-2. With other wire from battery touch the iron frame (Y); if the lamp lights, then somewhere there is a ground of one of the spools in contact with the frame.

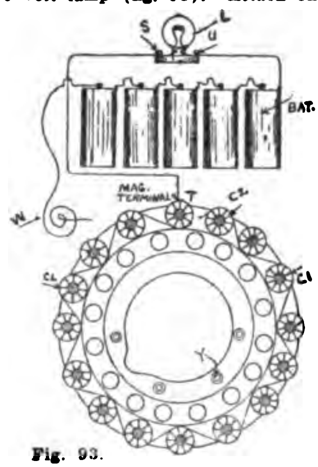

Fig. 93.

The next step will be to find out in what particular portion of the winding, the ground exists.

Attach the test wire (W) to metal part. This can be easily done by inserting the end, under nut (Y) or temporarily making a soldered joint at the point where permanent ground was formerly attached, if there is a ground, lamp will then light.

Loosen the coils one at a time and shake vigorously, or move up and down, this will cause the light to flicker—or go out and on when you reach the coil or section where the ground is located.

The ground can sometimes be removed by cleaning out dirt and metallic particles and revarnish with a special oil-proof varnish which can be obtained of Ford agents. Common shellac will not do.

Note—Illustration shows coil plate reversed. Bolt holes and recess for cam shaft should be on top as shown in fig. 85, page 803.

***Dead Points.**

On the older model Fords which did not have the ¾ inch magnets, there were certain dead points where, if spark lever was placed in certain notches in quadrant, the engine would not respond with increased speed. On the late magnetos as the magnets pass from one end to the other as it revolves there is no dead point—see below and page 265.

CHART NO. 351—The Ford Magneto. Testing Magneto Coils.

*Note; while illustrations show magneto coils as being round, they are now made oblong, with oval pole pieces, so that as soon as the magnets pass away from one pole, they begin to influence the next—thus there are no "dead points." **Varies according to distance between magnets and coil cores and strength of magnets, see page 864-J. †See page 303, how to test polarity of a magnet. Before assembling, test magnets and chalk-mark N poles. After assembling, test correctness, by passing compass around fly wheel, close to outside of magnets—the needle should reverse as each pair of poles is passed. If placed wrong, needle will turn cross-wise and tremble. ‡See pages 864-J, 806. **See also, page 823.

†Indications of Weak Magnets.

(1)—Dim lights. (2)—Frequent backfires, or explosions in the muffler when running—possibly blowing the muffler up.

The magneto is often blamed for trouble that lies elsewhere in the electrical system. A weak current will often be caused by dirt or waste collecting beneath the terminal contact spring on the crankcase cover. To clean; remove the three screws holding the binding post, remove the post and spring, and clean as per fig. 92, chart 351.

Check up the wiring for short circuits or grounds.

To reach the magnets it is necessary to remove the engine from the car. The common method of doing this is to remove radiator, dash and steering gear and lifting the engine out complete. By the method herein outlined the base of the engine is left in the chassis and the dash and steering gear are left undisturbed. Two experienced men can readily remove an engine and place it on the bench in 30 min. by this method.

*To Remove Engine.

1–Drain radiator.

2–Remove four bolts at universal joint.

3–Remove rear spring shackles and pull rear axle back. (The rear of the car must first be blocked up.)

4–Disconnect radiator stay rod.

5–Remove the two bolts holding the radiator to the frame and remove the radiator.

6–Unsnap cammutator and place it to one side.

7–Remove spark plug wires.

8–Shut off the gasoline and remove the feed line from the carburetor.

9–Disconnect the exhaust manifold from the exhaust pipe and remove both intake and exhaust manifolds from the engine.

10–Remove fanshaft bracket and timing gear case.

11–Remove the two bolts holding the pans to each side of the base and knock the pans down out of the way.

12–Remove the base bolts.

13–Remove the transmission case after loosening the reverse, low and brake transmission bands.

14—Lift the engine from the frame and place it on the bench. The lifting may be done with a hoist. It is quicker and easier, however, if three men take a hold of it and lift it out by hand. One should straddle the engine at the rear and the other two should be at each side at the front.

Tearing Down the Engine and Testing.†

1–Clamp the engine on the bench.

2–Test the magnets on the flywheel, as shown in fig. 2. The block of steel should just hang by a corner. The weight of this test block happens to be the same as that of the Ford camshaft gear. Failure to hold indicates weak magnets.

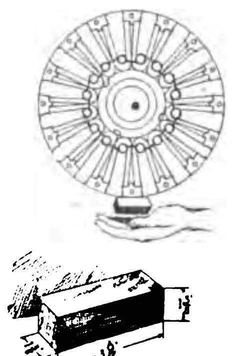

Fig. 2.

3–Remove the bolts holding the flywheel and transmission to the crankshaft.

4–Remove the flywheel, magnet and transmission unit, placing it face down on the bench.

5–If trouble is suspected in the magneto coils, these may be tested, as shown in fig. 3. The two test points are connected to a 110-volt alternating current line, per fig. 33. **The main ground of the coils is disconnected and each coil tested for shorts, grounds or open circuit.** (see also fig. 93, chart 351.)

6–Chisel the heads from the ends of the brass magnet retainng screws at the rear of the flywheel; when reassembling use new screws.

7–Turn the fly wheel transmission assembly over and set it upright in a square box placed on the bench.

8–Remove the wires holding the central magnet - retaining bolts.

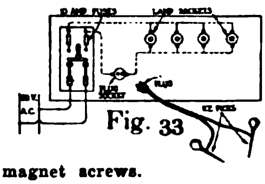

Fig. 33

9–Using a bit brace screw - driver, unscrew the outside magnet screws.

10–Using a bit brace socket wrench unscrew the central retaining bolts. Clean all parts.

Fig. 33 shows a testing outfit using four 32 c. p. carbon lamps.

Building Up the Magnets.

1–Place the new magnets on the flywheel in the same order that they were in the box that they were shipped from the factory—**that is, so that the legs that do not attract each other are together. This means that like poles, or N&N and S&S poles** are placed together. (see fig. 91-A, page 805.)

2–Catch all the central retaining bolts in place, but do not tighten.

3–Slip the outside spools under the magnet ends.

4–Drop the magnet clamps onto the magnet ends and catch the brass screws into their threads.

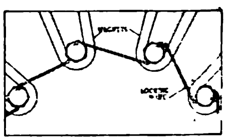

Fig. 5—Method of locking bolts by running a wire through the heads

5–Using a brace screwdriver, bring all of the screws down snug.

6–Pinch the ends of the magnets in with a pair of pliers until the sides of the magnets rest against the spacer on the clamps.

7–Tighten the outside brass screws.

8–Tighten the central retaining bolts.

9–Using (stovepipe or brass) wire, lock the central bolts in position. The wire should be inserted as shown in fig. 5, (when holes are about in position shown) as this creates a tendency to tighten instead of loosen the bolts.

10–Knock the four corners of each magnet clamp down over the magnets, so that they cannot interfere with the coils later.

11–Turn the assembly over and head the brass screw at the rear of the flywheel. Before assembly, the engine should be inspected for loose or worn bearings and if any are found they should be cleaned and adjusted.

†Assembling the Magneto.

1–Replace the flywheel-transmission assembly onto the crankshaft flange and secure it with two

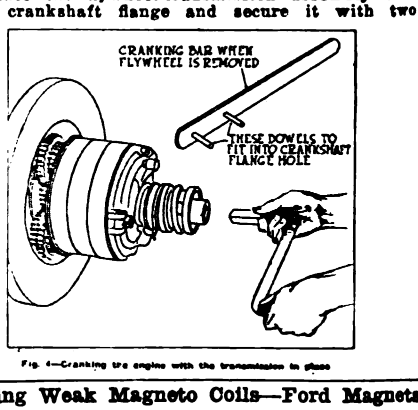

Fig. 4—Cranking the engine with the transmission in place

CHART NO. 352—Testing and Fitting Magnets. Testing Weak Magneto Coils—Ford Magnets. Removing and Disassembling Engine. *See also, page 783. †See also, page 864-J. (Motor World.)

—continued from chart 352.

opposite flange bolts. Draw these bolts up snug.

2–Using the crank, as shown in fig. 4, turn the flywheel and note whether the magnets interfere with the coils. The magnets are set 1/32" from coils.‡

3–Replace the two other flange bolts.

4–Tighten all the flange bolts. A short piece of round stock, wedged through one of the holes in the coil flange and caught behind the magnets, holds the crank so that the bolts may be drawn tight.

5–Again using the crank as shown in fig. 4, crank the engine quite fast. While cranking, short circuit the magneto contact point with the cylinder using a screwdriver. A fat blue spark shows the magneto to be O. K.

6–A putty knife may be used as a gage for testing this distance. It may be found necessary to shim up the coil-supporting flange.

7–Place the locking wires in the crankshaft flange bolts as explained on page 806.

Replacing the Engine.

Before replacing the engine in the base, the base should be thoroughly cleaned. The rivets holding the supports to the base should be tested to see that they are tight. All bolts should be inspected.

1–Place the standard Ford felt packing on each side of the engine base, setting it in heavy oil.

2–Lift the engine up and set it in place. Be careful not to slide it around any more than necessary. Three men can do this easily.

3–Line up the holes in the base with a small drift.

4–Replace the front gear cover.

5–Drive all the base bolts through their holes, from the bottom up, and catch the nuts onto the threads. Two men, one with a speed wrench on the nuts and the other holding the bolts, can quickly fasten the engine to the base.

6–Slide the transmission bands in place.

7–Bring the lugs all together at the top and wire them together tightly with a single strand of stovepipe wire, or use a clamp similar to that shown in fig. 16, chart 324.

8–Place short lengths of felt gasket at A, B and C, as shown in fig. 6. Place 3/8-inch asbestos wicking and grease in the corners at D and E.

9–Then place the standard Ford felt transmission gasket in place. The double thickness felt and the asbestos wicking stop up the points that tend to leak.

10–Slide the transmission housing in place. Using a screwdriver, pry the bands into place.

11–Knock the housing down flush and tighten the two rear retaining bolts.

12–Using a thin socket, or check nut wrench, tighten the transmission bands.

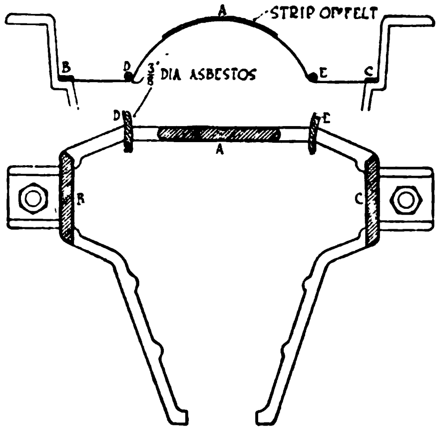

Fig. 6—Method of packing all joints to prevent leakage of oil.

13–Replace the balance of the housing bolts and bring them up snug.

14–Slide the rear axle and drive shaft back into place and secure it there.

15–Assemble the engine fittings, such as fan, commutator, wiring and manifolds.

16–Replace the radiator assembly hood and floor boards.

Later Magnets 3/4 Inch.

To install 3/4 inch magnets of the latest type so electric lights can be used; as the crankcase and the transmission cover are similar, the necessary parts include No. 3250-D magneto coil assembly, one set of 3/4 inch magnets, sixteen magnet clamps No. 3277, and sixteen magnet clamp screws. (Former magnets were 5/8 inch.)

*Remagnetizing Ford Magnets.

The usual and proper method to remedy weak magnets is to replace them with new ones. The Ford Co., do not advise everyone to attempt this work. This however necessitates taking down engine and then reassembling. This makes a costly job and is a big job. Therefore different methods will be given to recharge magnets without removing from car.

Charging with storage batteries: Five or six, 6-volt storage batteries should be about right. Refer to fig. 7.

To prepare the magneto for recharging, first disconnect the wire (A) which goes from the magneto terminal on the transmision cover to the coil on the dash.

Next remove the transmission cover (B) so you can look at the magneto. Locate the brass studs on the rim of the flywheel which holds the magnets in place, and have some one turn over the engine very slowly until one of these brass studs is in line with an imaginary line drawn about 1 in. or so from the magneto terminal, to the left of the latter and paralleling the frame. Another way is to place an ordinary small compass on the transmission cover about 1 in. from and to the left of the magneto terminal, at the same time turning the engine slowly until the needle of the instrument is parallel with the engine.

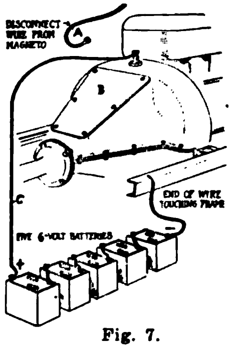

Fig. 7.

The north pole end of the needle should point towards the engine when in this position.

Connections; Connect a wire from positive (+) terminal of the battery to the magneto terminal on engine, as shown at (C).

Next connect a wire from the negative terminal on battery, and make and break the circuit by striking the free end of the wire on some metal part of the engine.

Permanent connection should not be made, but only thirty or so momentary contacts, which, it is said, will reacharge the magnets much more satisfactorily than if permanent contact is made. (Motor Age.)

*Other sources of electric supply for charging the magnets are shown below and on next page.

Dry cells can be used if necessary. Use 48 connected in series-multiple as shown in fig. 4. Connect positive (+), or carbon poles with terminal.

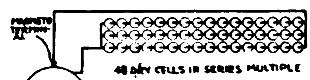

FIG 4

—continued on next page.

CHART NO. 353—Ford Magneto Testing—continued. Remagnetizing Magnets. Replacing the Engine.

*A magnet remagnetizer for Ford magnets is advertised in the back of this book. See also, pages 819, 864-J.
‡See also, page 864-J.

—continued from chart 353.

Resistance wire can be used: Use 13 ft. nichrome No. 16 wire or 8 ft. of No. 18. If German silver, use 35 ft. No. 16 or 22 ft. No. 18—in series as shown in fig. 6.

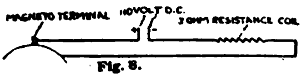

Fig. 6.

110 volt direct current can be used: To use, it will be necessary to use a resistance lamp bank, per fig. 5. Use twenty-eight 32 c. p. carbon filament lamps. Connect positive pole with magneto terminal. Connected as shown, gives 27½ amperes. To find positive pole, or polarity of any circuit —see page 452.

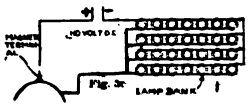

Fig. 5.

(From Automobile Dealer and Repairer.)

Ignition Troubles.

We have dealt with magneto troubles. We will now take up the coils and spark plugs.

Although this matter has been fully treated on page 236 and under heading "Digest of Troubles" (see page 578) we will touch on a few of the important points here.

Coil Units.

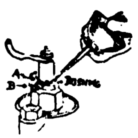
The four coil units on the Ford are contained in a metal box with a slanting cover (see fig. 88, chart 349) which enables them to be taken out of the box, without removing it from the dash. Some of the 1914 and 1915 metal coil boxes had straight covers, but when this type are used on a cowl dash, (1916 or 1917 body,) the units cannot be taken out, without taking the box off the dash.

The earlier wood box coils, were much inferior to the present type, and the Ford Motor Company makes an exchange proposition on these wood box coils which should be carefully considered before replacing defective coil units in wood box coils or installing new points.

Missing of Explosion.

Troubles due to the commutator, magneto terminal, weak magnets or grounded magneto coils, was treated on pages 804 to 806. Other causes, are spark plugs and coil vibrators.

Spark Plug Cause of Missing.



See page 233.

The first and most probable cause of missing is due to the spark plug points being set **too far apart** or **not far enough**—for instance if set too close there will be a tendency to miss at slow speed; if **set too far apart** missing will occur frequently. (see pages 233 and 299.) The spark plug may have become **fouled** from too much oil, which is common trouble—see pages 235, 237.

Fig. 7

Spark plug on the Ford is a ½ **in. pipe thread,** long body per page 238.

Gap should be 1/32 in. and if point is bent as shown the oil will have a tendency to drip off (see pages 233, 236 for testing a spark plug. A worn dime makes a good gage, as shown in fig. 11.

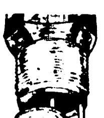


Fig. 11A dime as a spark plug gage.

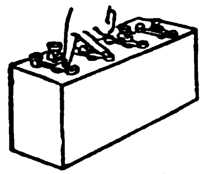
Coil Vibrator Points.

Too close contact between adjusting screw and vibrator will cause tungsten points to pit, which results in sticking and frequently burning away the tungsten and often putting the coil out of action and invariably causes missing.

This may be remedied by cleaning the points with fine emery cloth, or as explained on page 234, or by the use of a fine jewelers file which is made for the purpose. But is is advisable to be very careful and file flat. (see also page 809.)



To test the vibrators of a coil see page 236.

When "direct" current is used for ignition such as a storage battery or "direct" current dynamo, the tungsten points on a coil pit up very bad much more so than on an alternating current magneto. That is why a magneto interrupter point wears longer. Alternating current is much easier on tungsten points because the current is being constantly reversed from negative to positive or positive to negative. (see page 284 and last three paragraphs in chart 117).

Too high a voltage or excess of current will cause excessive sparking and will pit the points and cause them to stick or weld together.

Adjusting Vibrators.

With the spring held down, the gap between the vibrator points should be slightly less than 1/32 inch. Then set the lock nut so that the adjustment will not shake loose. Each coil unit should be adjusted to take about 1½ amperes, as measured by an ammeter. (see pages 234 and 236.)

Hard starting due to vibrator adjustment. If there is **too much tension** on the vibrator springs, the weak current generated by the magneto at cranking speeds will not be sufficient to cause the vibrators to buzz and it will be difficult to start the engine. **Too little tension** will not let the vibrators respond quickly and the engine will run unevenly.

A Defective Coil Unit

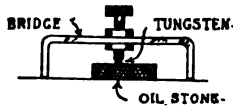
Can be detected by noticing if the vibrator buzzes without producing a spark at the plug. Then the suspected unit can be exchanged with another unit to make sure that the trouble is actually in the coil unit. A punctured condenser is indicated by a heavy spark at the vibrators and a weak spark at the spark plug.

If the engine has a tendency to miss when driving over rough roads, this may be due to the coil units not fitting tightly in the coil box. The bouncing of the car makes the coil units touch the metal cover of the box and causes misfiring.

Sometimes, misfiring is due to the wooden lining of the metal coil box being damp and allowing the electric current to leak across from one terminal to another.

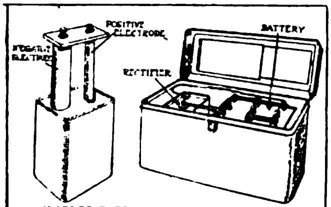
**Dressing Vibrator Points.

The coil point screw is clamped, by means of two nuts, to the center of the metal strip. The strip is moved forward and backward over the oilstone, thus securing a true surface on the tungsten point, which makes it last much longer without grinding. A flat jewelers file is often used also.

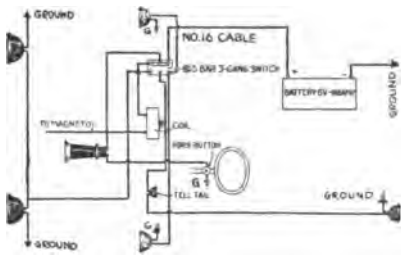


A Battery Charger.

A battery charger illustrated in Fordowner recently is shown in illustration. With this device the alternating current is rectified to direct current. The magneto is intended to supply the current for charging. The rectifier and battery are placed in a battery box on the running board.



WARNER BATTERY CHARGER, FOR FORDS
The Ford magneto may be used to charge storage batteries for the lighting system, by the use of this rectifier



Electric Lighting.

Although this subject is treated on page 812, this illustration which is a good example, recently appeared in Automobile Dealer and Repairer, and reproduced here. Note the completeness of the details and layout. A 100 ampere hour, 6-volt battery is used, which can be placed in a metal battery box located on the running board

Of course, the battery must be recharged when exhausted. If nitrogen, 6 volt lamps are used the amperage used per hour would be about 6½ amperes, therefore battery would give approximately 15 hours actual service. If spot light is used it will take 2 amperes more.

Ether, Picric Acid and Gasoline.

Q.—Can ether or picric acid be used for increasing power for racing? A.—Yes, nitrous ether has been used but is dangerous.

Nitrous ether is purchased in glass tubes and is put on ice at least 8 hours before attempt to handle, as heat from palm of hand will explode it and the glass is liable to put your eyes out. Mix one ounce to five gallons gasoline and you may have to add a little more gasoline or a little more ether to get the best results. Ether you buy in pound cans is suitable for easy starting in cold weather, by mixing half ether and half gasoline and put it in a small tank on dash, using a small priming pump to squirt it in the intake pipe. This ether can be handled without danger, as long as it is kept away from a flame.

Picric acid; put one pound of picric acid in a glass bottle and fill with gasoline or alcohol, keep in a cool place, stir twice a day for one week before using. The picric acid will not all dissolve, but pour out all the liquid, straining it through a fine seive and mix the same proportion as you do ether. You can use both together by equally dividing them. There is one point to watch closely; don't get mixture too rich. Picric acid is injurious to engine and will increase heat.

Miscellaneous Electric Systems.

*The Master Vibrator

Is a single coil (high tension), connected in series with the ignition system as explained on page 232 and illustrated in fig. 103 below. It improved the earlier wood box coils much more than it aids the latest metal box coils having tungsten points. With this system of

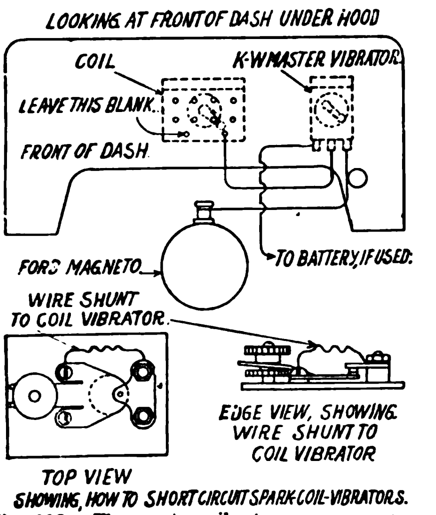


Fig. 103.—The master vibrator—see page 232.

ignition, but one vibrator is used, see page 232 for the general principle. The same commutator and other parts of the coil system are used, with the exception that the vibrators are short circuited by pieces of wire, as shown in fig. 103, and fig. 6, page 264. (The master vibrator is not supplied by Ford Co.)

Atwater-Kent Ford Ignition System.

On page 248 a detailed description of the Atwater-Kent ignition system is given. The Ford Atwater-Kent system is similar in design to that described, and is furnished complete with cam gear cover plate which makes a neat and secure fitting when the old commutator is removed (figs. 1 and 2, page 810). The distributor is accessibly arranged in a vertical position.

†**When fitting this system,** the old coil box on the dash is removed and a single unit non-vibrating coil, contained in a small box, is mounted on the dash. The radiator should be removed, to facilitate the placing of the cam gear cover, also the fan assembly and the spark control rod. The timer and wires are then removed, but the hexagon nut is retained to hold the bevel gear of the new system.

With this system the magneto can be used entirely for lights—or entirely removed, thus reducing the drag due to the magnets.

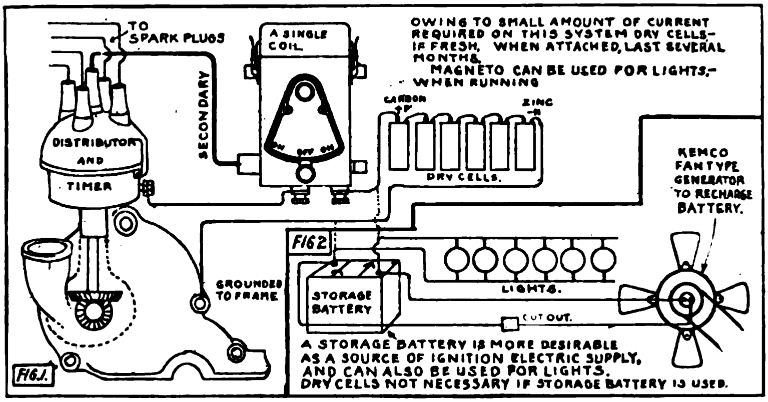
These single spark battery systems, and high tension ignition magnetos are especially adapted to racing Fords and speedsters. The more accurately timed single-spark, which these systems give, is especially valuable at high engine speeds and gives more power.

CHART NO. 855—Miscellaneous Electric Systems. Dressing Vibrator Points. A Battery Charger.

*See also pages 264, 232, 230. †When fitting an Atwater-Kent system to a Ford the piston is placed ¼ in down after top, see page 316. **See also, page 284. Ford genuine vibrators are made of spring steel, heat treated and grain running one way; thus increasing resiliency. The points are high grade tungsten.

Atwater Kent Ignition and Kemco Generator.

Figs. 1 and 2 show how a direct current generator, of which the Kemco fan-type generator is a good example, can be used to keep a storage battery fully charged. The storage battery then furnishes a reliable source of electric current for lighting and other purposes, even when the engine is stopped. A cut-out is provided in the circuit as shown in cut, to keep the battery current from flowing back through the generator, when the engine is not running. (The Atwater-Kent Co., Philadelphia, Pa.)



Figs. 1 and 2.—Atwater-Kent Ignition and Kemco Generator.

*The Kemco Electric System For The Ford.

Generator: Consists of a direct current generator (13 lbs), driven from crankshaft by a Whittle V belt. It is mounted in the fan and charges a 6 volt battery which supplies current for lights, ignition and the starting motor.

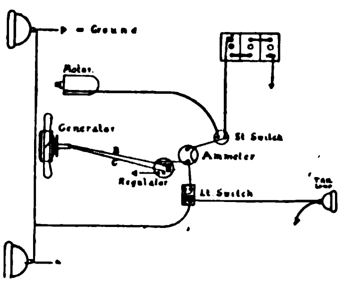


Fig. 106.—The Kemco wiring diagram.

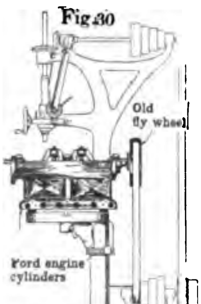
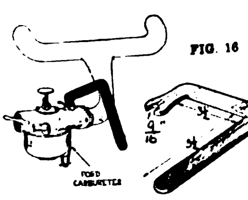
The starting motor is geared back 16 times. It is a series wound motor and starts engine through a roller chain connecting with sprocket on an overriding clutch connected to crank shaft.



Drill Press To "Run In" Ford Bearings, Etc.

Fig. 30. Ford main bearings, connecting-rod bearings or oversize pistons can be run or worn in by bolting the cylinder block to the drill-press table, with cylinder head removed and four ½-inch pieces under the corners between head and table to give clearance to pistons. A flywheel of the bolted-on type is drilled to fit the flange of the Ford crankshaft and bolted on.

The table is turned so that fly-wheel lines up with the drive pulley of drill press and is then belted up. An elevating screw is used to tighten the belt.

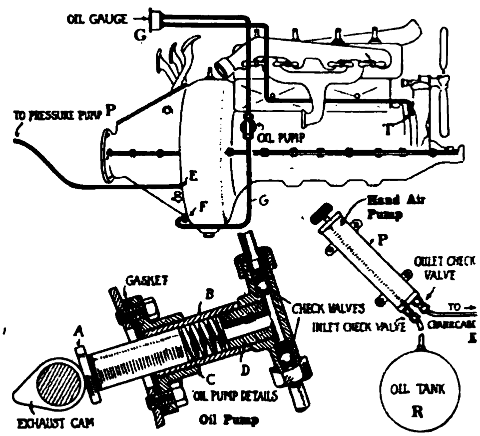


Ford Carburetor Wrench.

Fig. 16. A special wrench for tightening the carburetor to inlet manifold can be made of flat metal as per dimensions in illustration.

*Oiling a Ford For Speed.

Oil reservoir (R) placed at any convenient point from which oil is pumped by hand oil pump (P) to crank case (E). From here it is pumped by small



piston oil pump to oil gage (G) on dash (thence to timing gears (T).

The oil pump is placed opposite No. 4 exhaust cam by drilling hole large enough to permit head (A) to pass through. Pump parts are made of brass tube (B) screwed to flange (C) having 4 holes for cap screws. Crank-case is tapped and leather gaskets inserted between. Piston of pump is made of steel. Bushing (D) is fitted into (B) to which remaining part of pump is screwed. Check valves and parts are shown.

Oil pipes are ¼ inch copper tubing using solderless connections. At (F) pet cock is removed and a fitting screwed into its place and tubing (G) leads from this to lower part of oil pump. A hole is drilled at (T) and tapped to take connection. (Motor Age.)

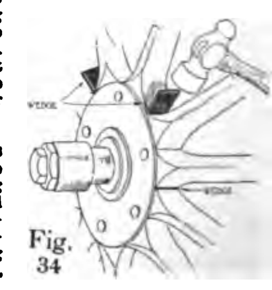


Fig. 34—Loose spokes in Ford wheels can be tightened by driving a piece of galvanized iron 2x1¼ in. forming a wedge. Looseness is due to drying out of spokes. See also, page 762.

CHART NO. 356—Atwater-Kent Ignition. Kemco Electric System for Fords. Miscellaneous.

Other concerns who manufacture Ford electric starting and lighting systems are Westinghouse Electric Co., Pittsburg, Pa.; Gray and Davis, Boston, Mass.; C. F. Splitdorf, Newark, N. J.—see page 823. *See also pages 814 and 816 and page 864-A for Ford electric system for enclosed cars.

For a Ford Mechanical Starter description, write A. L. Dyke, Pub., Granite Bldg., St. Louis, Mo.

SPLITDORF MAG-DYNAMO.

Note—This motorcycle matter should have been with pages 843, 844 and Insert No. 3, but this being the only page in the book to spare it was placed here.

This is a combination of a magneto and a dynamo. The **dynamo armature** which generates "direct" current is placed above, (1) being the commutator. The magneto **armature** (U), is a regular armature with wire revolving, **generating** "alternating" high tension current, and is placed below. The two are entirely separate and independent.

The fields or magnets are not of the "permanent" type, but are of the "electro" type, excited in the **first** case by the current in the storage battery, or by the first few revolutions of the generator. The dynamo and magneto are separate and distinct otherwise, but combined in one unit.

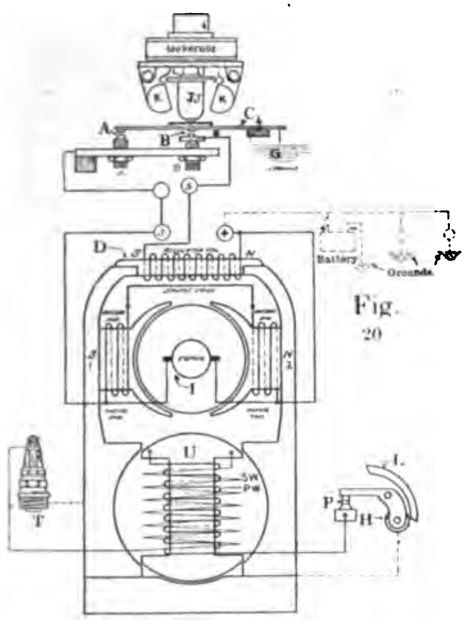

Fig. 20

Magneto Part.

The magneto part of the "mag-dynamo" supplies current for ignition. Its armature (U) is a double wound (SW-secondary—PW-primary) high tension revolving type. The interrupter parts are shown; P—platinum points of contact breaker; L—cam; H—roller grounded with frame or base; T—spark plug; P—points are set 015" and spark plugs .020" gap.

Dynamo Part.

The dynamo generates a "direct" current—which **charges a storage battery**, and also supplies current for **lights**. Armature is driven by a gear from the magneto or lower armature. With the battery "floating-on-the-line" (see page 834), the unit has a maximum output of 8 amperes at 7.5 volts at 1400 r. p. m. of engine, equal to 30 m. p. h. with average road gear.

Cut-Out Principle.

Principle of the automatic cut-out used with the dynamo is as follows:

When the rider gives the starter pedal (see page 844), a downward thrust as in starting, the mechanical governor part (J) is forced down by centrifugal action of arms (K), which acts upon the spring (O), bringing the main line contacts (A) together; this allows about 1 or 1½ amperes to flow through the field winding (and armature) magnetizing it so that the lower or ignition armature may produce sufficient current to spark the engine.

If the engine is stiff or hard to turn over the starting switch is depressed allowing four amperes to go through the shunt fields and armature, the starting switch merely cuts around the contacts (A) so that a strong magneto field is obtained when the rotation of the armature is slow. Of course when the battery is disabled, a powerful thrust on the starter pedal will rotate the generator armature fast enough to generate sufficient current to magnetize the field enough to furnish a spark at the plugs.

As the speed of the motorcycle increases up to about 30 m. p. h. the charging current also increases to about 3½ amperes, then through the increased action of the governor spring a second contact at (B) comes into action, this connects the regulator or bucking coil (D) into the circuit and magnetizes the soft iron core (N & S), which you will note, is magnetized the same way as the field coils, this action bucks the magnetic field of the generator armature and drives the magnetism down to the ignition armature field, weakening the generator field and strengthening the magneto field.

The ignition current is a straight high tension current from magneto at all times. When first starting the magneto field is energized from the battery and when running, from the generator. Otherwise that is all the connection the ignition or magneto has with the dynamo or generator.

Timing Magneto on "Mag-Dynamo."

Indian, Thor, Merkel, the piston is placed 5/16" from top of compression stroke with breaker box advanced. On the **Harley-Davidson** (Dixie magneto), 9/32"; **Excelsior,** 13/32"; **Pope,** ½"; **Dayton,** 3/8''.

A handle bar switch is also provided which should only be used when engine is cold and hard to start. When switch is depressed (with battery on circuit) it permits battery current to flow through the shunt fields (and armature), and provides a powerful magnetic field; in consequence, a hot spark is produced at low engine speed. Excessive use of switch will exhaust battery.

Adjustments of Mag-Dynamo.

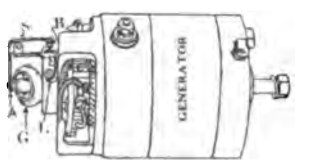
To adjust cut-out and current control; with engine idle and all lights turned off, remove regulator box cover and adjust the current control contact screw (A); the correct setting of the contact points should be between .015 and .025 inch. This setting will permit battery to discharge about 1 to 2 amperes. On the other side of the regulator box the setting of the main cut-out contacts can be made as follows: With engine running slowly loosen lock nut and turn current control screw (B) several turns to the left, increase the speed of engine until ammeter shows 3 ampere charge. With engine running at this speed (approximately 1200 r. p. m.), turn screw (B) to the right until ammeter needle drops back approximately 2 ampere charge, then set lock nut.

The fuse used in the circuit is a 15 ampere fuse. **Positive pole of battery** is connected to fuse block and negative terminal is grounded.

In case of failure of battery, three dry cells can be utilized, connected in series with carbon pole to fuse block and zinc grounded.

Splitdorf DU-1 Generator.

The principle of the mechanical cut-out on the DU-1 Splitdorf motorcycle lighting and battery charging dynamo is shown in this illustration. Note the centrifugal action of G, on armature shaft, causes a sleeve at higher speeds, to press against arm (A), which through hinge (S) makes contact at (B). It is similar to the "mag-dynamo."



On the late model motorcycles, the Dixie magneto (Insert No. 3) is used, and a separate and distinct dynamo is mounted separate. This dynamo is termed the "DU-1" dynamo as above.

CHART NO. 357—Splitdorf "Mag-Dynamo" for Motorcycles. Used on former models of Indian an others, as shown above under timing. See page 843 for Remy and Insert No. 3 for Dixie Motorcycle Mag neto and Indian Motorcycle Engine.

**Electric Lighting.

‡The bulbs supplied on present Ford cars for the electric head lamps are 9 volts, 2 amperes, and best results will be obtained by securing lamps of this voltage and amperage when replacement is necessary. (see fig. 87A, page 803, see also page 434.)

If a lamp burns out it will be necessary to replace it by removing lamp door.

Should the door be removed care should be exercised not to touch the silver-plated reflector or the bulb with anything but a soft, clean rag, preferably flannel.

To focus the lamps turn the adjusting screw in the back of lamp in either direction until the desired focus is attained. (see page 433.)

21 or 27 c. p. is standard for headlights. For side lamps, 4 c. p.; for dash or tail lamps, 2 c. p. (see page 434.)

‡The model T Fords are fitted with 18-volt magneto, and therefore a 9-volt lamp in series would really last longer than 8 volt lamps in series, but light would not be quite so bright. The older models magnetos gave 12 to 16 volts, therefore 6 to 8 volt lamps were used—connected in series.

Nitrogen bulbs type C, are best (see pages 432, 434), but are more expensive.

When lamps are connected in parallel, 12 to 16 volt, one ampere, 15 candle power type B bulbs can be used.

Proper voltage: You should get good lights at eight miles per hour and the bulbs should come up to full candle-power at about twelve miles per hour.

If the bulbs do not come to full candle-power, and cast a yellowish light, you should use a bulb of smaller voltage.

If the bulbs burn too brightly, throwing an exceedingly white light at slow speeds, the bulbs are too low voltage and higher voltage should be used. In this case, the life of the bulb would be very short.

Wiring.

Wire—No. 16 flexible lamp cord, run through metal tubing or flexible loom (see page 426), is usually used for wiring.

*Lighting Connections.

Fig. 1 is a "series" circuit and is the way Ford headlights are connected up as sent out from the factory. (see fig. 87A, page 803). The new model Fords are fitted with an 18-volt magneto and therefore two 9-volt lamps in series should be used. The older Fords magnetos give 12 to 16 volts, so that 6 to 8 volt bulbs should be used.

SERIES CIRCUIT FOR ALL FORD CARS

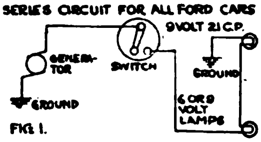


FIG. 1.

Fig. 2 shows a "multiple" circuit, in which the lamps are connected in parallel and there is a ground wire for each lamp. When this type of wiring is used, 12 to 16 volt bulbs should be used on old Fords, and 18 volt bulbs used with the new type magneto. Careful running of the engine, to avoid burning out the bulbs, will be necessary when the headlights are connected in this way.

LAMPS WIRED IN MULTIPLE

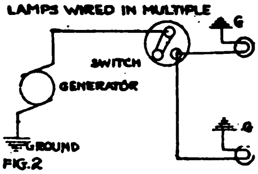

FIG. 2

Fig. 3 shows a "series-multiple" circuit. The headlights are wired in series. A pair of smaller bulbs for dash and tail lamps are connected together in series and wired to the same switch. It is important that bulbs connected in series be of the same amperage, as otherwise one bulb will be liable to burn out.

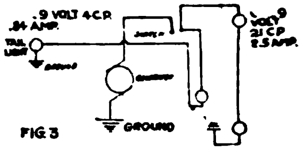

FIG 3

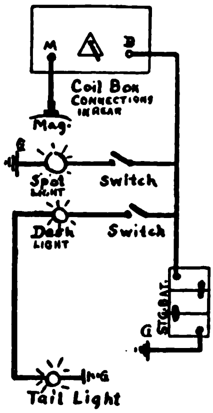
For dash and tail lamps, two or four candle power bulbs of 6 to 9 volts can be used according to model of car.

Storage Battery Connections.

For ignition, horn, and lighting—one terminal of the storage battery can be connected to terminal (B), rear of coil box, see fig. 87, page 803. The other terminal is grounded to frame of car or engine (make clean contact and draw tight with a bolt).



The wire to (B) connection on coil, should have 3 branches. One branch should connect, through a single pole switch, to a three-volt lamp on the dash. Then the wire from this dash lamp should proceed to a three-volt tail-lamp at the rear of the car. The remaining wire from the tail-lamp should be connected to the metal of the chassis frame. This places the dash and tail-lamp in series, so that if the tail-lamp should burn out or become disconnected, the dash lamp would also be extinguished, thus warning the driver. See foot note bottom of page 847, Packard Supplement.

Another wire should be connected, through a single pole switch to the spot light, the remaining wire from the spot light being grounded.

The third branch wire from the battery should be connected to the binding post on the left-hand corner of the coil box, looking from the radiator towards the dash. When the switch on the coil box is turned towards the binding post, to which the battery wire is connected; the battery will be connected for easy starting, and no other switch need be used.

The bulb for the spot light should be rated at six volts. The bulbs for the dash and tail-lights should be each rated at three volts. If desired, the bulb for the dash may be rated at two volts, and the bulb for the tail light at four volts. But they must be of the same amperage. Only two switches will be needed.

The usual voltage of storage batteries is 6 volts, therefore lamps of this voltage should be used.

The number of hours a battery will operate, depends upon the number and size lamps used and the ampere hour capacity of battery (see pages 433 and 441.)

When battery is exhausted it must be taken to a charging station and re-charged. There is a device known as the Warner battery charger, which it is claimed will rectify the magneto current from alternating to direct and battery can be charged from magneto. (see page 809.)

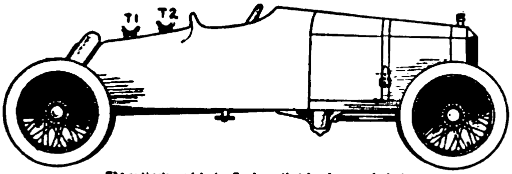
CHART NO. 358—Electric Lighting and Connections.

See also page 430. ‡The voltage of the Ford magneto varies from 16 to 20 volts at average speed, see p. 770, 823. For headlamps, use two 9-volt bulbs in series—see page 434. If one wishes the brightest light possible to obtain, use two type C bulbs (page 434), which are gas filled and give 27 c. p. The gas filled lamp will not last as long as the type B, but gives a brighter light. If type B lamps are used, use two 9-volt, 16 c. p.; both consume 2 amp. Order for D. C. base. See page 864C for c. p. and voltage of lamps used on the enclosed cars useing the electric starting system.

*See page 864-A for electric system of Ford enclosed cars.

*Speeding Up a Ford.

As I have helped in rebuilding several Fords that turned out exceptionally fast for the money invested in the job, I believe that I have gained some experience that may be of value to others, so will set down what I have learned, and it may be taken for what it is worth.



The author's model of a Ford car that has been made fast

There have been a few jobs turned out that ran into the thousands, you might say, and that were Fords in name only when finished. Of these I will have little to say, taking it for granted that what is wanted is something that is within the ordinary man's reach, both in a pecuniary way and, if he delights in doing his own work, in a mechanical way.

Division of Work.

The work naturally divides itself into two parts, the engine and chassis, or running gear. I will discuss the engine first, it being the most important part.

Engine.

The engine, as it comes from the factory, has bored cylinders, and as it is impossible, especially in a commercial way, to bore a perfectly true cylinder, the first thing you should do is to have your cylinders **reground** by a competent machinist, one who makes a specialty of this sort of work. Then you have a set of cylinders that are in line, have equal bore all the way through and are as near round as it is possible to make them.

The pistons I have used were cast of aluminum alloy, of course, and were equipped with non-leaking rings. Whatever make is purchased or if you have them made to order, see to the following things: There should be a rib or "reinforced run" from the piston-pin boss up to the piston head on the inside. Also several ribs should be cast across the inside of head. This both stiffens the piston and helps in carrying away the heat from the explosions. If you have the pistons made to order, it is advisable to have them cast and machined for two rings rather than three. This cuts down ring friction, lightens the part, and will hold compression as well as three or more rings if properly fitted.

****In fitting the piston, plenty clearance must be given**—from .007 to .008 at the top being about right. This may seem excessive, but remember that the expansion of aluminum is much greater than of cast iron.

This large clearance may lead to oil pumping and foul plugs, and so I have always turned and drilled an oil groove in each piston just below the lower ring groove as shown in fig. 2. The grooves are about 1/16 deep and 3/16 wide, having the lower corner rounded

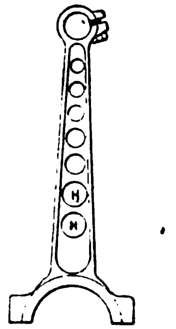


Fig. 1—The connecting-rod has been lightened by dressing with file and drilling holes through inside web

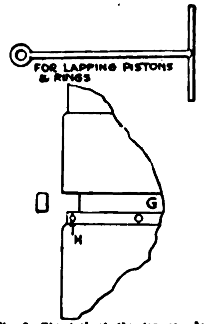

Fig. 2—The tool at the top can be used for lapping the pistons and rings. At the bottom is illustrated the preparation of piston and ring to prevent oil going into cylinder

off. There are eight ⅛-inch holes drilled through the groove at equal distances around the piston, slanting down toward the inside. The top corner of the ring should also be slightly rounded. As the piston goes up the rounded edge of the ring and the groove tend to slide over the film of oil on the cylinder wall, while in going down the sharp lower edge of the ring scrapes the oil in the grooves and it runs through the holes to inside of piston, and thus back to crank case.

Lapping Rings to Fit.

The rings should be of some good non-leaking type, or at least be step cut (see page 655.) Fit them in the cylinder with a gap of about .004, then lap them to a fit. In lapping them in, they should be placed on an old piston, cast iron is best, and worked back and forth in the cylinder, keeping the cylinder walls well covered with a mixture of exceedingly fine carborundum or some other abrasive and oil. (see page 650.) As the piston is moved back and forth, also give it a slight rotating movement. I have used a tool similar to the one shown in fig. 2 for this purpose. The wrist pin goes through the hole shown.

Job Repays Trouble.

This is a long tedious job, but you will be well repaid if it is properly done. It takes from 1500 to 2000 miles to wear in a set of rings under running conditions. Be sure and get all the abrasive from the cylinder walls and rings after the lapping is finished, or it will continue after engine is running.

You can lighten the connecting rods considerable by dressing them up with a file and drilling several holes through the inside web. This does not dangerously weaken them, judging from my experience. Do not drill any holes in the last inch toward the bottom, as this is where the most strain comes, and anyway this part of the rod is more of a rotating than a reciprocating mass. In one car the rods were chucked up and the lower ends turned out and bearings (made of Kelly metal) were cast, turned to fit and installed. After 2500 miles of driving, most of it at

CHART NO. 359—Speeding Up a Ford.

(By E. B. Williams in Motor Age.)

*See also pages 760 and 761 for additional matter. **See pages 645 and 651

—continued from chart 359.

high speed, the engine was torn down and these bearings showed practically no wear. This metal, if used, must be fitted with plenty of clearance.

Large Valves are Better.

You will secure better results if the valve ports and pockets are turned out and larger valves used. No trouble is liable to be encountered in boring the seats and ports from the top, but when going in from the side the tool will sometimes break through, and you will have to have the hole welded. It is best to do this before regrinding the block, as the heat, if welding is necessary, will warp the walls surrounding the weld. The ports can be enlarged $\frac{3}{16}$ inch and this is necessary if you expect good results. I have used tungsten steel valves, giving the stems plenty of clearance.

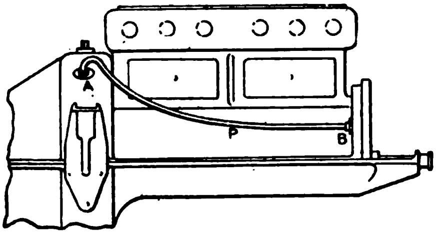

Fig. 4—One auxiliary oil system

The springs must be stiffened considerably, either by installing heavier springs, or by placing spacers between the upper ends of springs and the cylinder casting.

It is good practice to install adjusters, using the kind that screws into the valve push rod, it being necessary to anneal, drill and tap the rod. While you are about it, drill the length of rod to the head, but not through. This lightens the part and cuts down inertia, thus helping the valve to close quicker.

Cam Shaft.

At this stage we come to the camshaft, which should be of the high-speed type if you can afford it, several different makes being on the market.* I have secured good results with shafts taken from Ford cars of 1912 or earlier vintage. You will find them considerably different from the new type. If the regular shafts are used do not try changing the timing, as one tooth on the coarse pitched timing gears of the Ford throws the timing out too much.

Remove Magnets.

Leave out the magneto armature coil assembly, and remove the magnets from the flywheel, screwing back the brass screws and brass magnet supports only. It will be necessary to shorten the screws a little. They will kick up almost as much oil as the magnets, and considerable drag will be removed.

***Crankshaft.**

Now see that the crank shaft is perfectly true, then assemble the crankshaft and gearset and try out in the lathe, first seeing that the bushing in the driving-plate assembly is a good fit on the gearset shaft. If there is any wobble it will probably mean turning up both sides of the gearset-shaft flange and the back side of the crankshaft flange. Now reassemble and turn up the flywheel if necessary to make it run true. Take out the assembly and try on two perfectly level knife-edge testing bars for balance. If one side of flywheel turns down, take out material on that side until the wheel stays where you turn it. This may seem a lot of trouble, but it is essential that these parts be true and in perfect balance.

Gearset May Affect Bearings.

The power and added strain at high engine speeds will sometimes cause the gearset to whip out the babbitt bearing at the rear in what is called the front ball cap. This will in turn loosen up the rear main bearing. I have found it advisable to turn out the ball cap and equip it with a bronze bushing, fitting it rather loose on the gearset driving-plate assembly shaft to give lots of room for oil.

****Lubrication.**

It is good practice to fit some auxiliary oiling system besides the gravity one with which the Ford is equipped. If money is no object a force feed system can be installed, which should have leads running to all four cylinders, being tapped through the walls on each side near the bottom of the cylinders and also a large lead running to the front of the crankcase. I have secured good results by cutting a ⅞ hole near the top of the gearset case on the right side and running a piece of brass or steel tubing, also ⅞, to empty into the timing-gear case as per fig. 4. The front end need be only a snug fit in the case, but the rear end must have a flange which can be bolted to the gearset cover, using a gasket between. A sheet-iron partition can be installed just back of No. 4 cylinder. This can be made as high as it is desired to carry the oil level under the connecting rods. Of course every car intended for long distance should also have a hand oil pump convenient to the driver which will force oil from the reserve oil tank to the front of the engine.

High-Tension Magneto Not Used.

While I believe a good high-tension magneto to be the best ignition on earth, I have discarded it in Ford work on account of the additional power needed for driving. Turning a magneto armature over at two or three thousand revolutions a minute requires more power than is generally thought, in my estimation. I have used a battery distributor system because it is light, is easily driven and works on the open circuit idea, thus requiring only four or five dry cells for current.

Cooling

Some additional cooling is needed. I have found the large V honeycomb type of radiator to be best. You will find that it will probably be unnecessary to use a fan with one

—continued in chart 361.

CHART NO. 360—Speeding Up a Ford—Continued.

*See also page 819. "Special racing camshafts." **See also pages 816, 810.

Counterbalances which can be clamped to a Ford crank shaft and which the makers claim will increase the flexibility and power of the engine are manufactured by The Dunn Counterbalance Co., Clarinda, Iowa.

of these. If you are building a streamline body it will be better to have some radiator maker build one of the tall narrow kind, (see page 190 and also chart 366) to order, or you may purchase a stock radiator. If it is necessary to use the original radiator, have a good tinsmith build on an extra tank to the top, either back under the hood, or point it and extend it out in front. Anyway, the original equipment must be improved upon for fast work.

Carburetion.

For a carburetor I recommend a 1¼- inch type, with a 1¼-inch built-up steel-tubing manifold. The one illustrated in fig. 5 has given good results. No cast manifold is efficient, as the rough surface inside with

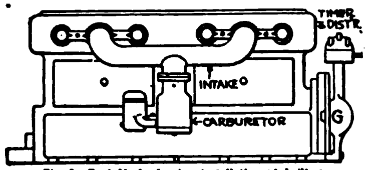

Fig. 5—Ford block showing installation of built-up manifold, carburetor and ignition apparatus

possible fins and irregular turns, seriously hampers the flow of gas.

Air Pressure.

It will be necessary to use air pressure on your gas supply as the carburetor should be set high, thus shortening the manifold.

Inlet and Exhaust Manifold.

Each end of intake manifold has a collar brazed or welded about 5/16 inch from the end; also the exhaust pipes, which are of steel tubing and run straight out through the hood. A copper-asbestos gasket is slipped over the end of manifold and makes a tight fit between the collar and the cylinder casting. Manifolds are held on by crows' feet, which slip over the original studs and bear against the outside of the collars.

Running Gear.

When we come to the running gear we have two things to consider. If the car is to be used for fast track work only, by all means lower it. But if you want it for other work too, you will probably have to leave it up in the air, and sacrifice some efficiency.

The best way to lower the front end, to my notion, is to have a new axle made similar to the one illustrated below in fig. 3. It leaves your frame strong and rigid, and an added advantage is that your radius rods are still in a straight line.

The rear end of the frame can be lowered by cutting off the side members just in front of the rear cross member and using steel forgings as

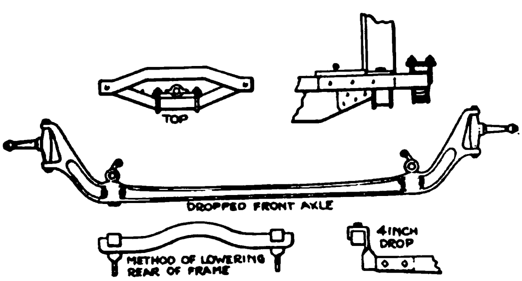

Fig. 3—Top—Method of lowering front end of frame by lengthening frame out and installing extra front cross member. Center—Dropped front axle. Bottom—Method of lowering rear end of frame 4 in.

shown in fig. 3. The front end if a cheaper construction is desired, may be lowered as shown in fig. 3, by riveting pieces of channel iron on the sides of the frame, letting them stick out in front about 5 inches. An extra cross member, similar to the regular Ford front cross member but with a high instead of a low center, is riveted across the front to the two, new side extensions. This sets your front axle ahead enough to clear the radiator, and the amount of frame drop depends on the shape of your new cross members (as can readily be seen), which carries the spring. With this method it will be necessary to lengthen out your radius rods and the starting crank.

Assembly Should Be Kept Rigid.

In tilting the steering post it is desirable to keep the assembly as rigid as possible. Have it bolted to the dash securely, blocking behind the dash plate with a wedge-shaped piece of hardwood shaped to fit the space caused by lowering. It will be necessary to drill a new hole in side of frame for bolt'ng down the bracket. You can block under the bracket where it tips from the frame with steel washers before bolting.

Steering.

The steering-gear connecting rod and the spindle-arm connecting rod should both be stiffened. An easy way to do this is to place a piece of small channel iron or steel tubing alongside the rod and bind the two together with several layers of tape, taping the whole length of rods, and then shellacing the whole job. This is cheap, easy to do, and makes a permanent job.

Axle.

See that the axle tips toward the back of the car at the top. The nearer vertical the axle is set, the harder it is to steer, and when the top of the axle gets ahead of the bottom, it is almost impossible to keep the car in the road.

A good gear ratio for a car put up like this one is about 2½ to 1. While I have always made my own special gears, several concerns are making and advertising them. Some makes sell for $15.

While you have the rear end down see that the differential gears are a good fit on the inside ends of the axles. These sometimes get loose and tear the key seats out of the axle.

The rear hub brakes on the Ford were only intended for holding the car when standing still, and if used when running they do not last long, and are not very efficient at that. The best brakes I have used so far were secured from Los Angeles, Cal., costing $16 per set. They have large drums and external contracting bands lined with raybestos.

Be sure and see that the transmission bands are a perfect fit on the drums and are not adjusted too tight. They can set up quite a drag if not properly set.

Speed Thus Obtained.

I had one of these cars do 68 m. p. h., and another one equipped with wire wheels 71. Of course, if economy is no object a new cylinder head with overhead valves and camshaft, wire wheels, etc., can be added, the stroke lengthened and in this way a few miles per hour gained, but for the man of moderate means the foregoing described car will go fast enough and furnish lots of pleasure in the building.

Cost.

The job I have described will run from $200 to $350, depending on how much of the work the builder is able to do himself.

I have not taken up the construction of the body, as that depends upon the taste or ability of the man who is building the car, also upon the use to which it is to be put. For racing a pair of bucket seats and a gas and oil tank bolted to the frame will get by very well, but are not comfortable or very clean. The body shown on page 818 is good, being neat in appearance, can be made comfortable, and offers little resistance to the wind. While it is not drawn to scale, the proportions are near enough right to give the idea. There is a gas and oil tank in the rear compartment, with the spare being slung on the extreme rear. This body should cost you about $150 at the average body builders.

Don't forget your hood straps, and have them very substantial.

Lowering the Frame.

The most important point in converting a Ford into a speedster is the lowering of the frame, because this car presents an awkward appearance with bucket seats and big gasoline tank when high off the ground.

Fig. 1—One of the simple methods used to underslung Ford front springs

If semi-elliptic front springs are used, instead of the regular transverse spring, the semi-elliptic springs can be fastened under the axle by means of a U-shaped piece of flat steel, per fig. 1. Thus, the front of the car can be lowered several inches with but little change in the front axle itself. However, the frame will have to be changed, or special spring hangers fastened to the frame to form supports for the front ends of these semi-elliptic springs.

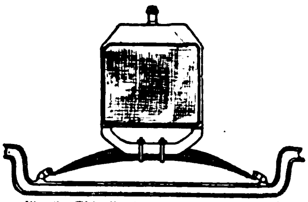

Fig. 3—This Ford front axle is a special forging with dropped ends

Fig. 3 shows how a special dropped front axle can be made to lower the front end of the car without making necessary inconvenient changes in the chassis frame.

Fig. 4—Method of lowering rear spring 4 inches. The end of the panel was cut off and a gooseneck fitted as shown

Fig. 3, chart 361, shows how 4 inches can be cut from the rear end of the frame on each side and the regular Ford cross member of the chassis frame supported on two goose necks made from flat, bar steel. This also will give a frame about 4 inches lower than the stock car.

Fig. 2 shows how the rear of the frame can be lowered by using the brake arm studs in the rear axle housing to fasten a forked steel bar from the axle to the frame. About two inches forward from the fork the spring shackles are bolted and the regular cross spring suspended from them. This gives about a 4 inch drop. (Motor Age.)

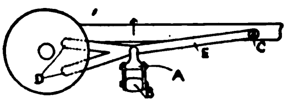

Fig. 2—Underslung rear spring. Forked rod B was anchored at the brake rods D and at the frame at C. Spring B was shackled to the rod by A

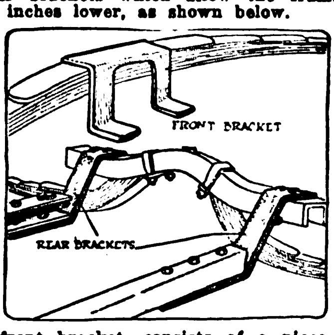
Another Method of Lowering Frame.

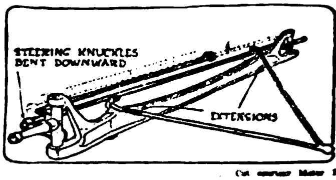
The work can be done by any good blacksmith and will not cost more than $15. The principal changes in dropping the frame are in making front and rear brackets which allow the frame to be hung 6 inches lower, as shown below.



The front bracket, consists of a piece of iron bent as shown, and made out of ½ by 2-inch stock. The method of attaching this is clearly indicated. The top is clamped over the spring, and the bottom ends are bolted to the cross frame member.

The form of the rear bracket is also shown, and its attachment is even simpler than the front. The frame is sawed off and the two brackets are bolted in place. Care should be taken in making the change not to alter the position of the axle relative to the frame backwards or forwards.

The attachment of the front bracket requires that the axle be pushed forward a certain amount —probably 8 inches. This must be compensated for by welding pieces in the radius rods running to the front axle.

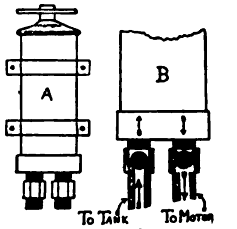


The Sketches Show How the Ford Frame May be Lowered.

The lower position of the crank-case requires that the steering knuckles be bent downward so that the tie rod will clear it. (Newsabout Fords.)

*Auxiliary Oiling.

The present oil system in the Ford engine, while suitable for all ordinary purposes, is inadequate for high speed. The oil rotating with the fly-wheel is caught in a small funnel and carried through a ⅜-inch tubing to the timing-gears flowing to the engine case where it lubricates the moving parts of the engine. This funnel can hold only a certain amount of oil and at any speed the tube can handle only a ⅜-inch stream.



Home Made Oil Pump

The funnel should be made larger, the long way, and higher to increase the weight there, and the tube replaced with one 7/16 inch in diameter.

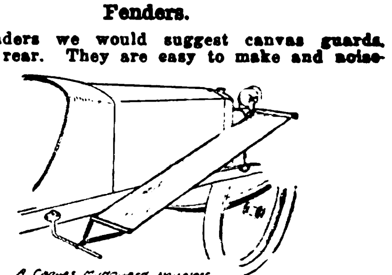
An auxiliary pump is frequently connected to engine as shown just above. An old tire pump can be converted into a pump as follows:

An old tire pump is cut off about six inches below the handle. A metal handle substituted for the wooden one as shown in the drawing. The bottom of the pump is removed and carefully soldered and the air outlet soldered up. Two check valves, requiring no solder, are fitted to the bottom of the pump by drilling and tapping. The valves are, of course, inserted so that they will act in opposite directions. The valve allowing oil to enter the engine allows the oil to be forced out of the pump, but will not allow it to re-enter. The other valve, working in the opposite direction, permits oil to come from the supply tank to the pump when the handle is pulled up. When the handle is pushed down one valve closes while the other, (the one permitting oil to enter the crankcase), opens.

The supply tank may be located where most convenient and is connected to the pump by copper tubing. The pump is placed under the front seat in a position where it can be operated easily.

Fenders.

For fenders we would suggest canvas guards, front and rear. They are easy to make and noiseless. Put a couple of coiled springs at the lower ends, and they will never sag. (Newsabout Fords.)



A Canvas Mudguard, Noiseless and Easily Made—Mudguard Support Also Makes Good Lamp Bracket

ART NO. 362—Lowering Frame for Racing—Miscellaneous Speed Pointers.

e: This matter is collected from various authoritative sources. Writer has not personally tried out any of devices. *See also pages 810 and 814.

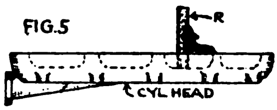
Cylinders.

If the car has been driven over two or three years, it will be probably advisable to have the cylinders rebored to the Ford standard of 1/32 inch oversize. While this will only add about one-half horsepower to the engine on account of the larger bore, the fact that the cylinder casting will have aged sufficiently to attain its permanent set, will have more influence on the power of the engine than is often supposed.

*Compression.

It is, perhaps, not generally known that the cylinder heads on the Ford cars have not always been the same. The cylinder heads used a few years ago were not as deep as those used on the latest models. †To obtain higher compression (which is necessary for high speed work), it will be well to secure one of these old style cylinder heads. They can be identified by comparing them with cylinders of the latest type, using a depth gauge as per fig. 5.

FIG.5



Depth of cylinder head

These high compression cylinder heads give more power, but they are harder on the bearings and make the engine more liable to knock, so that many owners are very glad to trade them for cylinder heads of the latest type, if the difference is pointed out to them.

It is true that different compressions affect the power of explosions and that an uneven compression ratio in different cylinders will, consequently, cause an engine to jerk. If the compression is excessively high it can keep the spark from jumping the gap in the plug.

If the old style cylinder head cannot be obtained, it is possible to plane off about one-eighth inch from the bottom of the cylinder head and thus increase the compression of the engine to about 70 pounds to the square inch. The work must be carefully done, so that a true surface is obtained, or water leaks and loss of compression will result. Good gaskets should be used between the cylinder head and the cylinder blocks, so that no compression will escape. By the use of Prussian blue and a scraper, it is possible to fit the cylinder head to the cylinder block without the use of a gasket, thus reducing the compression space about 1/32 of an inch.

Unless the compression is the same, the engine will not be in good balance and less of power will result. The power lost when one cylinder does not fire is far more than 1/4th, and this is due largely to a loss of balance.

Valve Springs.

One of the most important features necessary to obtain increased power is good valve action. Valve springs are cheap, and it pays to install a new set of valve springs occasionally, even if the old ones do not seem to be worn out. Lively springs close the valves promptly and this is especially necessary if the engine is to be run at high speeds. If it is to be used for racing and the last ounce of power is desired, it may be advisable to use special valve springs that are stronger than the regular type but which are more apt to break the valves and are more noisy.

It is, of course, understood that the engine will be kept free of carbon and the valves ground frequently, if used for speed work.

**Valves and Cam Shaft.

In order to obtain the highest possible speed, it is necessary that the valves be timed differently than is standard practice. For racing, it is necessary that the valves be given a greater lift, that is, open farther, and that the cams be so designed that the valves be opened and closed more quickly. Now these quick-action valve cams cause greater wear and tear and make more noise. It is also true that the engine will not run smoothly on high gear at speeds of less than 20 miles an hour, so these special cam shafts are only of value when the car is used for racing only. **For use as a speedster,** on average roads, the regular camshaft is probably the best. It is easy to set the timing gears one tooth ahead and so open the valves earlier, but this also means that they close earlier and so little is gained by this practice.

It is sometimes asserted that the speed of the Ford engine is purposely limited by the small size of the ports or valve openings. This is probably done so that careless drivers will not run the engine too fast, but if it is intelligently handled, it is true that greater power can be obtained by enlarging the ports or valve seats. A wide seating for the valves is not necessary and tends to restrict the flow of the gases. One thirty-second of an inch is wide enough, but requires more frequent grinding and valve adjustment than a wider seating, as it wears more quickly under the hammering action of the valves. Fig. 2, (page 818) shows how the valve ports may be bored out larger, but great care should be taken not to break through the sides of the water jackets, as the walls are not always uniform thickness, due to the displacement of the cores when the castings are made.

Getting a large charge of fresh gas in the cylinders for each explosion is one of the essentials of maximum power. Along these same lines is the necessity of getting the old burned gases out quickly. For this reason, a muffler is often omitted from racing cars, although a car cannot lawfully be operated without a muffler on the roads of many states. However, a cutout is easily attached, and if used in moderation, serves the purpose very well. If no muffler is used, the end of the long exhaust pipe should be somewhat flattened, so that the sound waves will be somewhat broken up as they emerge. A number of small holes, and diagonal saw cuts will also aid in giving a free exhaust without undue noise Or, it is possible to remove one of the baffle tubes from the muffler, or bore addi-

—continued on next page

CHART NO. 363—Increasing the Speed of a Ford—by Murray Fahnestock in Fordowner.

*In Ford races held in Chicago, there was not a car in which attempts had been made to increase compressio by reducing compression space, and cast iron pistons seemed to predominate. Gear ratios used were fro 2¾ to 3 to 1. For long races, radiators were fitted with tanks for extra water capacity.

**Sometimes the inlet valve is made to open slightly earlier for speed work. In this case engine will not idl down very well. See also page 909 and pages 793, 629 and 640 on compression. †Clearance between pisto head of Ford high compression cylinder is about 1".

tional holes in the muffler tubes, so that a comparatively free exhaust is secured without losing the muffling qualities altogether.

Carburetion: To obtain the maximum speed from the engine, a larger carburetor, say the 1¼-inch size, can be used. This will not be economical of gasoline, and the engine will not run as smoothly at low speeds, but with a larger carburetor and a larger intake manifold, which should be smooth inside, the engine can draw in fuller charges at high speed.

The piston rings certainly create friction as they rub against the cylinder walls, and if the top ring is so well fitted that no compression will escape past it, the two lower rings are unnecesary, as they cannot stop any gases that do not reach them. Some owners prefer to fit special piston rings, see page 655, at the top of each piston and claim that it makes the engine run more freely. However, if only one ring is used, greater care must be taken to keep that one ring in good condition.

If the rings are fitted on an old piston, they may be lapped in by using emery and a more perfect fit obtained, and then they may be placed on the new pistons for actual use. If lapped on the new pistons the grooves (for the rings) in the pistons are apt to be worn.

Pistons: For high speed driving it is necessary that the pistons should be rather a loose fit in the cylinders, as otherwise they are apt to seize when the inevitable expansion due to heat occurs. This does not mean that it is not necessary to rebore cylinders or fit new pistons on old cars, for in such cases, the cylinders and pistons are apt to be worn oval, due to the thrust of the connecting rod and so do not have the proper clearance all around.

Light pistons are certainly an advantage, and the use of aluminum has much to recommend it, especially if new pistons are to be fitted in any case, as then the additional cost will not be so much. In case the cast iron pistons are used, they can be greatly lightened by careful drilling, care being taken not to weaken them too much. Most of the holes should be drilled near the ends of the piston pins, for if drilled on the sides, where the thrust occurs, they permit the oil to be squeezed out and spoil the lubrication where it is most needed.

Light reciprocating parts are the secret of high speed and power. If we consider structural iron work, we will notice that beams are made very heavy along the edges where the strain occurs and often the center is only a light lattice of thin steel strips. (see fig. 1, page 813, for a drilled rod.)

It is possible to balance the rotating masses of the engine, but it is not practicable to balance the reciprocating weights, except to a small extent. But by making the parts lighter, the unbalanced forces and power-absorbing vibrations are greatly reduced. It is more important to lighten the connecting rod at the piston end than at the crankshaft end, because the piston end of the connecting rod has a reciprocating motion while the big end bearing has a rotary motion.

Connecting rods: It is also important that the four connecting rods be of equal weight and that the four pistons have the same weight, so that they will tend to balance each other and reduce vibration.

The alignment of the connecting rod bearings is important. This can best be tested in special jigs which are part of the equipment of every branch of the Ford Motor Co. If one wishes to align these bearings, the piston pin can be placed in one end of the connecting rod, and a cylindrical pin, the size of the

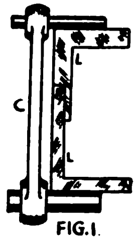


FIG. 1.
Alignment

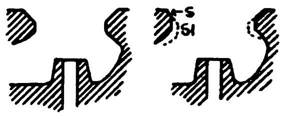

FIG. 2.
Increasing Port Opening

crank pin, placed in the other end of the connecting rod, and two steel squares used to make sure that the two bearings are in perfect alignment with each other. (fig. 1.) This only tests the alignment in one direction and to test them in the other plane, it will be necessary to use the same tools and a perfectly flat surface, so that the distances from the pins to the plane surface can be measured and made equal on each side. (see figs. 1 and 11, page 646.)

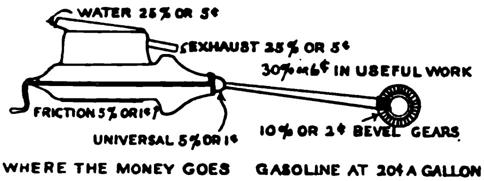
Crank shaft: It is important that the crankshaft be in good running balance, which is different from being in balance when at rest. It can be tested by revolving the crankshaft at different rates of speed, between centers. The bearings of the crankshaft are also important, and, after they have been scraped to a good fit, the engine should be driven by an outside source of power until the bearings fit perfectly.

Flywheel: It hardly pays to reduce the weight of the flywheel, especially if the power of the engine is increased and a higher compression used, but the flywheel alignment can be tested by holding a steel pointer near it when the engine is running, for a wobbly flywheel involves a loss of power.

Ignition: For ordinary road use, the Ford ignition system will furnish about all the sparks required, but to obtain the very highest speeds, the more accurately timed sparks of the high tension magneto are an advantage. If the Ford ignition system is used for high speed work, the magneto and magneto coil assemblies should be of the latest type and the vibrators should be adjusted more tightly, so that there will be less lag in the ignition. The spark can be advanced by bending the rod from the lower end of the steering column to the timer. It is also well to be sure that the timer is in good condition and that the spring holding the roller against the segments is strong and quick acting. It may be even an advantage to fasten an additional spring beside the one already in place.

Lubrication: Adequate lubrication plays an important part in the maintenance of high engine speeds. A good quality of thin oil, which does not burn easily, should be used. Heavy oils exert a constant drag, and are not needed, if the engine is in good mechanical order. Oil holes can be drilled in the connecting rod bearings and larger oil grooves cut in the bearings. It is also well to fit a much larger oil pipe and oil funnel. The oil pipe can be drilled with holes opposite each connecting rod, so as to supply a good oil bath.

CHART NO. 364—Increasing the Speed of a Ford —continued.



Where the Money Spent for Fuel Goes—Diagram Shows Different Points Where Losses Are Greatest.

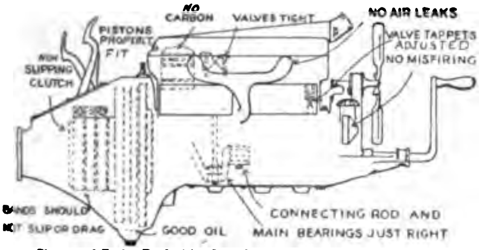


Diagram of Engine Emphasizing Parts Requiring Attention for Saving Fuel.

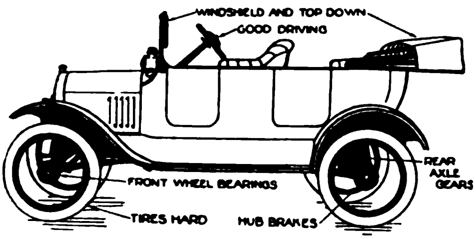
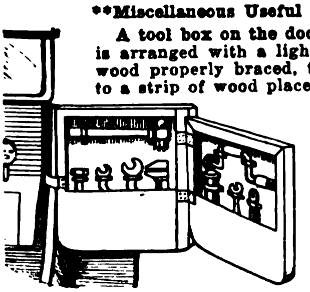


Points at Which Gasoline Can Be Saved On Complete Car.

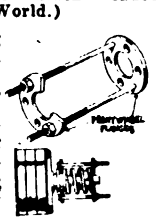
How To Save Gasoline.

The illustrations point out where care should be exercised in order to prevent loss of power by decreasing friction and waste. To gain power means a saving of gasoline. The illustrations show where if parts are kept in proper order, there will be a saving of power. Excess of power and loss of gasoline would come from poor driving, too much flooding carburetor, windshield constantly up, dragging brake bands, etc., see the three illustrations above. (see also page 802.) (Fordowner.)

**Miscellaneous Useful Devices.



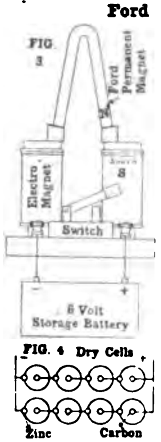
A tool box on the door—The front door is arranged with a light door of strips of wood properly braced, the hinges screwed to a strip of wood placed up and down behind the metal door lock; the inner door spring catch fits nicely in the notch left by removing the center cross brace next the leather stop. Then a pocket made of canvas or leather in the lower portion of each door with a strap or two to keep the tools in place. Replace the door lining and put new strips of gimp, tacking with black headed tacks as it was before. (Motor World.)



This is a device for compressing the Ford clutch spring. The end plates are Ford front wheel flanges, one being cut away, so that it may be inserted over the shaft, behind the spring. Two bolts connect the plates and by tightening the nuts, the plates are drawn together, compressing the spring. With this device, only one pair of hands needed to remove the pin.

Motor speed per mile. The crank shaft of a Ford car makes, 2,446 revolutions in one mile, and when running at a rate of twenty-two miles per hour it turns over 897 times every minute.

Ford Magnet Remagnetizer.



It is not necessary to remove the flywheel from engine when remagnetizing Ford magneto magnets with this device. Simply remove transmission case cover so that the ends of the magnets are available. Use a compass (see fig. 8, page 808) to determine North pole of each magnet and chalk them, also chalk the South pole of the remagnetizer. Place the S pole of remagnetizer so it will be on the N pole of the magnets. Turn the flywheel over after remagnetizing one magnet and remagnetize each magnet separately. After remagnetizing, check the polarity of all magnets with compass again. The connections are shown in fig. 3. The storage battery can be either a 6 or 12 volt battery. It is possible to use 6 or 8 dry cells if connected as per fig. 4.

Magnets of all types of magnetos can be charged with this remagnetizer. When remagnetizing magnets which are separated from the magneto, it is well to place a "keeper" across the magnets until placed on the magneto. It is also advisable to rap the magnet a few times with a piece of wood while being remagnetized. See advertisement, page 864-J.

***Larger Valves.

Valves if made larger will permit slightly more gas to enter and will increase compression and power, but heating will also be increased, therefore a circulating pump or larger radiator may be necessary. A valve lift of 5/16 inch with a valve seat 3/32 inch, measured across slanting face would be about right.

Valves are now 1 5/16 inch outlet and 1 1/2 inch diameter across widest part, but for racing, valves 1 1/2 inch diameter outlet and 1 11/16 inch across widest part would be better. The valve ports can be enlarged to this size by reaming and grinding. Tungsten valves of 1 5/8 inch are sometimes used.

Circulating Pumps

Of unique and simple design are manufactured, by Giddings & Lewis, Fon du Lac, Wisconsin.

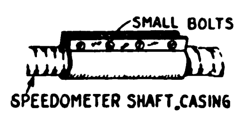
Muffler and Out-Out.

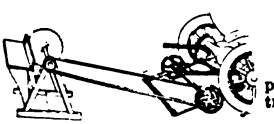
The construction of the Ford muffler and method of attaching one type of cut-out is shown on page 84. The outside diameter of exhaust pipe of a Ford is 1 1/2 inches, therefore a cut-out would be required which would fit over same. (see page 606.)

****Paints for Fords.

No. F113—Blue ground, first coat.
No. F115—Body blue color varnish.
No. F751—Body varnish, clear.
No. F104—Black fender, quick dry.

To repair a broken speedometer shaft casing a sleeve is used as shown in illustration. A layer of tape is applied first.





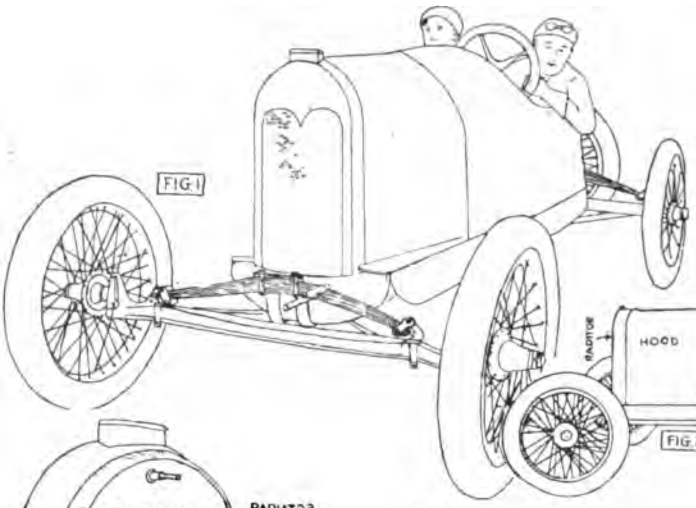
Power From Rear Wheels.

A device for this purpose is shown in illustration.

CHART NO. 365—How To Save Gasoline. Miscellaneous Useful Devices.

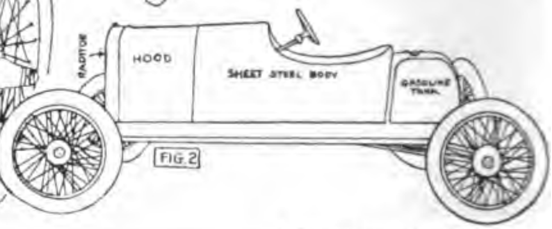
See pages 730 to 745. ***See pages 791, 609, 814. ****See page 509. **To repair a hole in a top—see page 84'

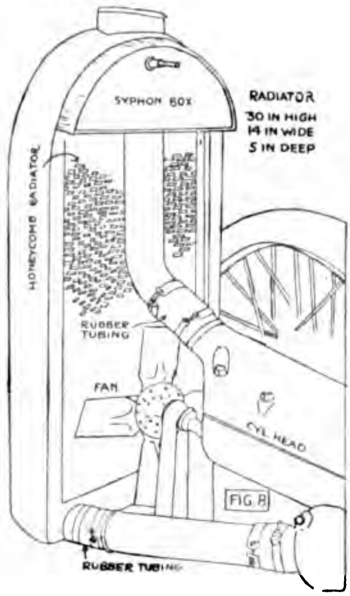
***Special racing camshafts, which will lift about 1/16" more than standard can be had of some of the supply houses.

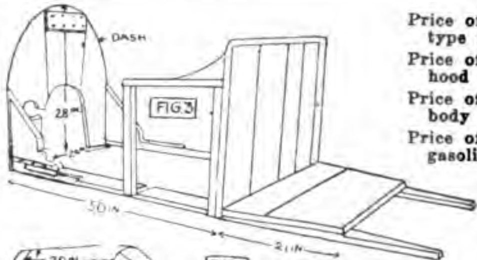


Specifications.

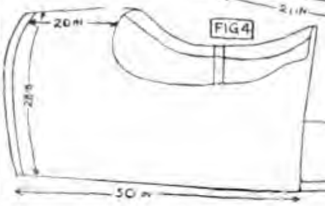
All dimensions of parts are given on the illustrations. Capacity of water is 4½ gallons, including tank at top of radiator. Gasoline tank is of 35 gal. capacity. Hood, body and tank made of pressed steel. Weight of entire body 300 lbs.

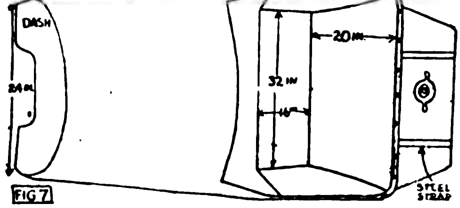


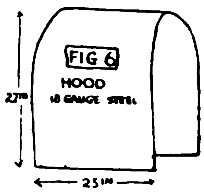


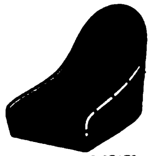


Price of special racing type radiator $50.00
Price of special racing hood 12.00
Price of special racing body 55.00
Price of special racing gasoline tank 8.00









RACING SEATS
For use on the speedster

Bucket type racing seats for the roadster, or speedster. The shell is heavy gauge steel, attached and braced to wooden seat bottoms, and upholstered with substantial imitation leather, known as mule skin. (Am. Auto Accessories Co., 621 Main St., Cincinnati, Ohio.)

Reducing Wind Resistance.

One way of increasing the speed of the Ford car is by reducing the wind resistance, by taking off the top, mudguards, and windshield. Also, by the use of special racing bodies, of which the body made by the Champion Racer Co., is an example.

The radiator is designed especially for racing and is high and narrow, thus reducing the wind resistance and improving the appearance. The radiating surface is of the patented bridge fin type and the construction is of copper throughout.

*Miscellaneous Parts Manufacturers.

Addresses of concerns who make a specialty of parts are as follows: Laurel Motors Corporation, Anderson, Ind.—cam shafts and valve in head cylinders (16 valves). Geo. L. Dyer, Champaign, Ill.—sixteen-valve cylinder head; Henry Pugh, St. Louis, Mo.—special work for converting Fords into racers. Ahlberg Bearing Co., Chicago, Ill.—ball bearing thrust washers for rear axles. Aluminum Mfg. Co., Des Moines, Ia.; McQuay-Norris, St. Louis; Butler Mfg. Co., Indianapolis, Ind.—aluminum pistons; G. H. Dyer Co., Cambridge, Mass.—pistons, reamers, Ford engine stands etc. Mott Wheel Co., Jackson, Mich.—wire wheels. (see also page 823.)

CHART NO. 366—Racing Bodies Reduce Wind Resistance and Weight.

*Note: This list was prepared sometime ago.

Combination Bodies For Model "T" Ford Chassis.

The illustrations, figs. 3 to 9, show how several different types of bodies for commercial use can be made from the lot of detachable parts in fig. 10.

In certain cases individual pieces of parts shown in fig. 10, have more than one use, for instance, the upright for the canopy top of the wagonette (fig. 5) and station omnibus (fig. 9), are used to support the rack of the hay and straw wagon (fig. 8), though when the last named is used, an additional pair of supports can be fitted.

The station omnibus body has double doors, for the base carries permanently a half door at the back, and the upper half for the omnibus use is attached to the detachable panels; the half doors are bolted together in use so as to form a single unit.

The seat backs used for the wagonette (fig. 5) and the station omnibus (fig. 9), also form a part of the sides of the closed van (fig. 7), and for the latter, the same canopy and upright are used. Instead of the upper half door and rear panels of the station omnibus, the van has a back panel hinged at the top, two supports being provided to hold it open when required.

The illustration, fig. 3, shows the chassis with the base (A) fixed thereto, which forms the ground work of all the variations. The base (A), it will be noted, includes the seat for the driver and his companion.

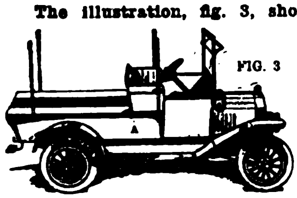


FIG. 3

Parts In Fig. 10 Will Make The Following.

Fig. 4. The Flat Lorry is made up of the base A (as on fig. 3), the float F and the uprights and the canopy C (fig. 10).

Fig. 5. The Wagonette is made up of base A (fig. 3), and the parts B and C (fig. 10).

Fig. 6. The Live Stock Dray has a lattice G (fig. 10), placed on base A (fig. 3), and float F (fig. 10).

Fig. 7. The Closed Van for perishable goods is made up of the base A (fig. 3) with parts B, C and D.

Fig. 8. Hay and Straw Wagon is made up of base A (fig. 3) and parts F and H (fig. 10), with canopy uprights.

Fig. 9. The Station Omnibus is made up from base A (fig. 3), with sides B, glass sides E and canopy C.

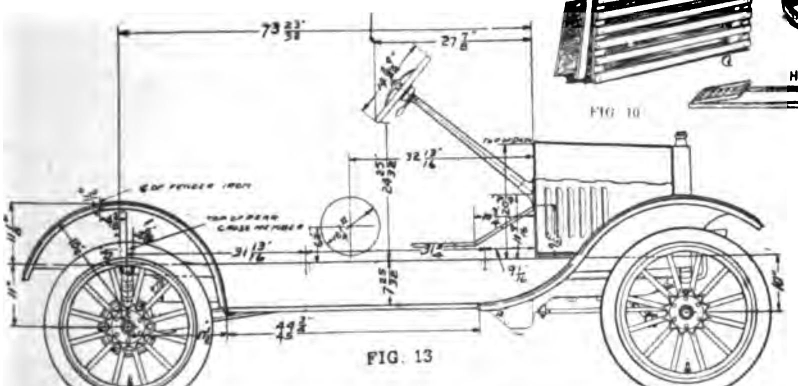

FIG. 13

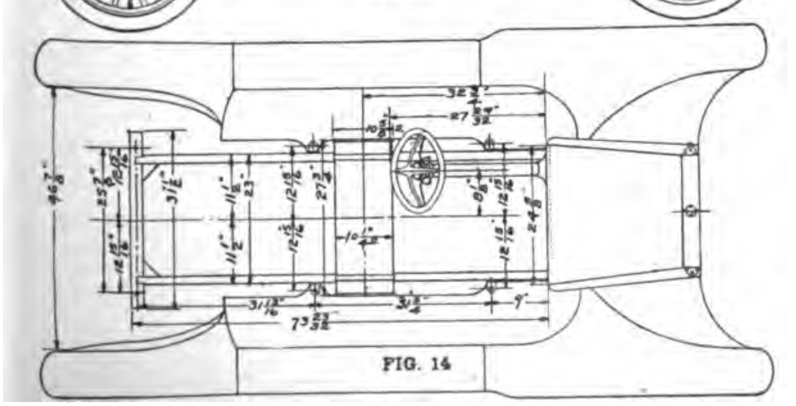

FIG. 14

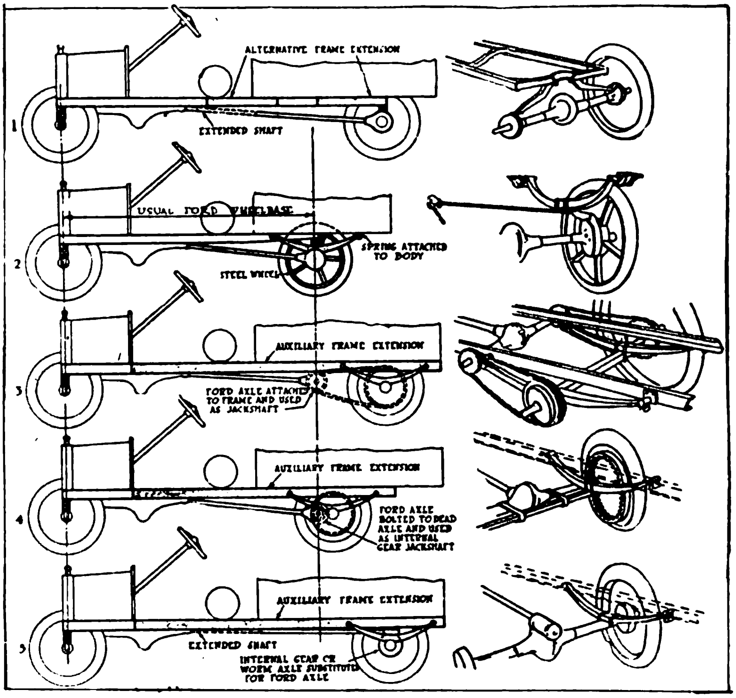
Principal Dimensions of Ford Model T Chassis.

These drawings, figs. 13 and 14 show the principal dimensions of the side view (fig. 13) and top view (fig. 14) of the model T Ford chassis. These dimensions will be of value when figuring measurments for bodies for commercial use which can be applied to the model T Ford chassis.

See page 825 for dimensions of the Ford truck chassis.

CHART NO. 367—Combination of Bodies As Applied to Model T Ford Chassis.



The five general types of Ford adapters, classified according to what parts of the Ford are retained in the converted vehicle, shown in elementary side and perspective sketches to indicate the changes made. The shaded portions indicate those parts which are added. Note that the Ford wheelbase is increased in all five classes except the second.

In No. 1 the Ford rear axle and spring are retained. The wheelbase is increased by the introduction of a frame section either at some point near the center or at the extreme rear. An additional piece of driveshaft of the same length as the increase in the Ford wheelbase is used to transmit the power to the rear axle.

In No. 2 the additional load capacity is taken care of through the use of steel wheels with housings carried on roller bearings independent of the Ford axle, which is used intact. Supplementary side springs attached to the body are employed.

In No. 3 the Ford axle is used as a jackshaft for a chain-driven rear-end truck assembly in unit with a frame extension.

In No. 4 the Ford axle is employed as a jackshaft for an internal-gear axle unit.

In No. 5 the entire Ford rear end is replaced by a truck frame addition and axle which may be driven either by worm or internal gears.

***Commercial Application of the Ford Model T Chassis.

The Ford is being rapidly adapted to a variety of commercial uses. In the illustrations, figures 1 to 5, show the five general methods used to increase the load carrying capacity.

Carrying capacity. The use of these rear axle attachments, shown in figs. 2 to 5, usually give a capacity of about a ton, ninety per cent of the load being carried on the heavy rear axle of the truck attachment. The gear ratio is generally about 6 or 7 to one, thus decreasing the speed, and increasing the power and hill climbing ability. A speed of 15 to 18 miles an hour can usually be obtained with a one-ton truck adapter.

The method shown in fig. 1, which merely changes the length of the frame, and uses the standard Ford rear axle system, is only suitable for those having light, but bulky loads to carry—such as, millinery.

Overloading the engine. The engine will not be overloaded, when used to pull one of these one-ton trucks, because the gear ratio* is so lowered that it can cope with the added load successfully. However, these trucks should be driven with reasonable care, and kept in good running order. The radiator should be kept well filled with water, the fan belt kept tight, and the carbon removed and the valves ground more frequently than is necessary with less arduous pleasure car use.

Speed. If these truck attachments are not driven at a higher average speed than twelve or fifteen miles an hour, the life of the engine and the truck attachment will be greatly lengthened.

**Trailers.

Trailers are divided into two general classifications. The two-wheeled, or cart type; and the four-wheeled, or wagon type. The two-wheeled type is of course much simpler and does not require any steering gear, being simply attached to the rear by a tongue and flexible connection. The attachment is usually made to the center of the rear cross member of the chassis frame, where the spring is fastened—the spring clip bolts often being used to fasten the trailer connection.

On level country roads, Ford cars are sometimes used to pull from three to five of the light, two-wheeled trailers. When much used for pulling trailers, it is advisable to change the bevel gear and pinion in the rear axle, so that a gear ratio of 4 to 1 can be obtained. This lessens the strains on the engine, transmission, and other parts of the power plant.

The capacity of the two-wheeled trailer, is usually about half a ton, although some are made of three-fourths ton capacity.

The capacity of the four-wheeled type of trailer, is usually one ton or more. But a one-ton trailer is about as large as should be used in connection with a Ford car.

Speed with trailer attached is but little below that of usual touring car speed. Twenty miles an hour is usual speed.

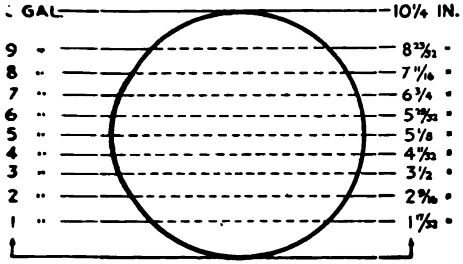
Load distribution, on two-wheeled trailers should be divided evenly in front of and behind the axle. Otherwise, severe strains will be placed on the connection between the car and the trailer, and the car may have to carry part of the load.

The coupling, or connection, between the car and trailer should be quickly detachable and provided with a cushion spring to absorb jerks and shocks when starting and stopping.

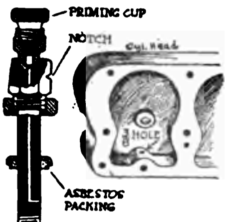
There are many firms who supply fittings for converting Fords for commercial use. One is the Unity Motor Truck Co. of Cleveland, Ohio, who manufacture fittings for converting a Ford into a 1250 lbs. truck or delivery wagon. The claim is that conversion can be made in 2 hours without drilling any holes.

CHART NO. 368—Converting the Ford for Commercial Use.

*Usually 4 to 1, sometimes 6 or 7 to 1. **See also page 746. ***See page 825 for Ford truck and page 821 for dimensions of the Ford model T chassis.



Ford 10 gallon gasoline tank. Measurement of depth of gasoline in tank. (See also page 801.)

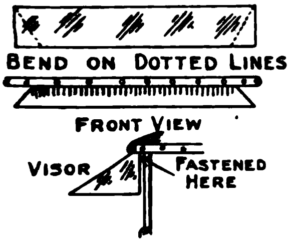


HOME PRIMING BOLT, FOR THE FORD

The cylinder head bolts are removed, and the heads drilled as shown. The special bolts are then inserted, and permit the motor to be readily primed

Priming Cups.

To fit priming cups to a Ford cylinder head, replace four of the cap screws with studs drilled as shown. Drill four ⅜" holes through inner wall of head. Home Light Co., 3353 Milwaukee Ave., Chicago.



Visor Windshield Protector.

To prevent rain and snow on windshield, a straight piece of fibre or thin sheet metal (6 to 10" wide) should have the corners bent at right angles, as shown by the dotted lines in the sketch. These side flaps keep the snow from blowing in at the sides and help to support the front edge of the visor. The rear of the visor should be fastened to the lower side of the front bow of the top, by means of a number of small, round head wood screws and washers. (Ford-owner.)

Gasograph is a gauge placed on dash which indicates quantity of gasoline in main gasoline tank. Adaptable for all cars using gravity or vacuum feed. Manufactured by New Standard Adding Machine Co., 3701-X, Forest Park Blvd., St. Louis.

***Tires.**

Two Ford cars may be so changed that both can have three and one-half inch tires all around without extra expense, except the excess of tire size. Remove the wheels without hubs from the front of one car and the rear of the other. Place thirty by three rims all around on one car, and thirty by three and one-half on the other. Put thirty-one by three and one-half tires on the car with three inch rims, and thirty by three and one-half tires on the other car. This gives equal size all around and extra size.

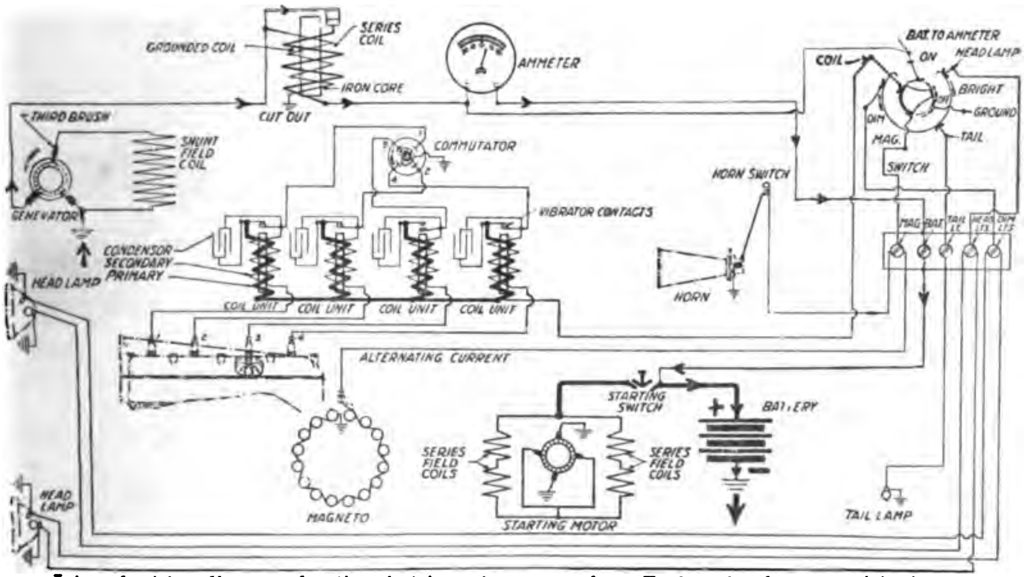
Spokes and rims can be had complete from Ford Co., ready to assemble to fit in hubs.

Extra oversize tires; the 30x3 front rim on a Ford will take a 31x3½ tire or a 32x4.

The 30x3½ rear rim will take a 31x4 or a 32x4½ tire. The 4 and 4½ inch of course will fit tight and are not recommended, but it can be put on by lapping the beads slightly.

Demountable Rims and Wheels.

The advantages of demountable rims are explained on page 551. Rims for 30x3½ tires all round will make riding easier, longer life for tires and only one size tire and tube to bother with. The Firestone Tire and Rubber Co., Akron, Ohio, make this equipment for **Ford and Chevrolet cars.** The outfit consists of 5 rims for 30x3½ tires, 4 applied to wood wheels and 1 spare; 24 hub bolts and socket wrench.



Internal wiring diagram of entire electric system as used on Ford enclosed cars explained on pages 864A, B, C.

Wiring: Single wire system. Frame serves as one wire and is connected with negative (—) terminal of battery.

There are eight circuits, each of which may be traced separately as follows: (1) Charging circuit (generator to battery as per arrow points); (2) Starting motor circuit; (3) Tail lamp circuit; (4) Head lamp circuit (bright); (5) Head light circuit (dim); (6) Ignition from battery; (7) Ignition from magneto; (8) Horn circuit.

Currents: Generator delivers 6 to 8 volts direct current with maximum of 12 amperes. **Battery** delivers 6 volts (direct current). **Starting motor** requires about 225 amperes at 4 volts. **Magneto** generates alternating current from 5 to 26 volts, with a maximum of 9 amperes. **Coil** secondary current in the ignition circuit carries a current of extremely low amperage at 15,000 to 25,000 volts.

CHART NO. 369—Accessories for the Ford. Wiring Diagram, see also, page 864B.

The speed of an engine can be determined by counting the number of impulses or movements one valve make per minute. Every two revolutions of crankshaft, valve will move once, therefore if valve moves 200 times pe minute, crankshaft would turn 400 times. This is about the limit one can count. Above this a speed indicator page 700, or tachometer, page 921, is necessary. The Ford magneto should generate 7 volts at 400 r. p. m. *See page 864-A for tires on Ford enclosed cars and also, pages 533 and 825.

Miscellaneous Ford Accessories.

Special Ford Wrenches.

Fig. 2. The 6 ft. one, with ⅝" socket wrench is used for removing the **universal flange** nuts from the rear without having to get under car. The 4½ ft. one, with 7/16" socket, is used to remove the **torque tube** retaining nuts after axle has been placed in the axle stand (fig. 5).

Fig. 3. Styled a jew speeder wrench; used in removing the 5/16" flange nuts and bolts holding the two halves of the axle housing together. (Motor World.)

Headlight control of a Ford, to keep the brilliancy or intensity of the lights equal at low or high engine speeds—see page 795.

Gasograph gauge, see page 823.

A spindle bushing remover is shown to the left. The knurled end is inserted through either bushing and pulled through until the expander slips over the inside end of the bushing. Then by tapping on the knurled end of the tool with a hammer the bushing is readily removed. By reversing the tool the opposite bushing is readily removed. Made of carbon steel, spring hardened. (G. H. Dyer, Cambridge, Mass.)

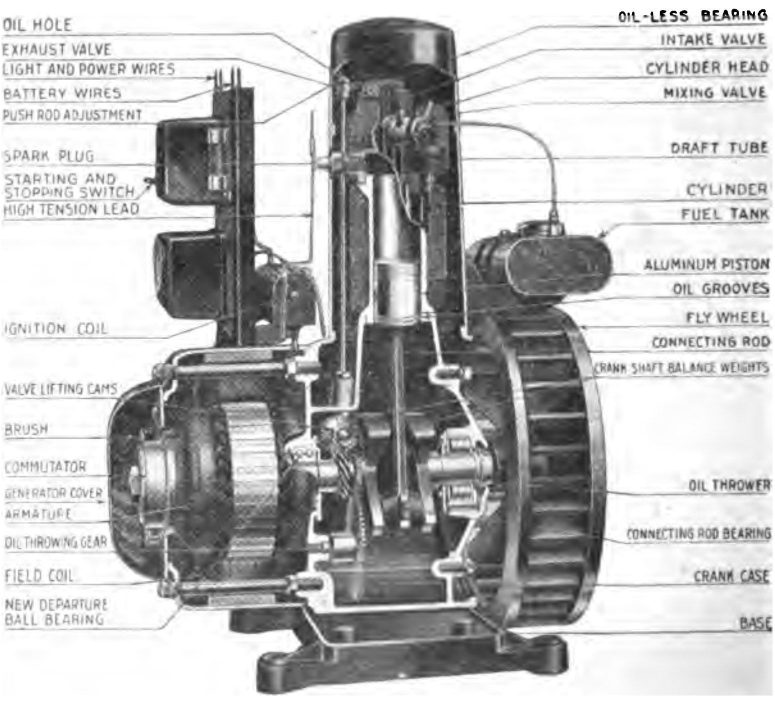
*The Delco-Light Plant.

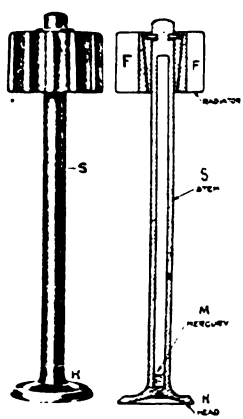
This subject is out of place here but will be shown, in order to give the reader an idea of the principle of construction of a modern farm lighting plant. The gasoline engine runs the dynamo and the dynamo charges the battery, which source of electric supply is used for lighting, power, etc. Manufactured by Domestic Engineering Co., Dayton, Ohio.

The mercury-cooled exhaust valve is used in some of the Delco farm lighting plant engines. With high duty internal combustion engines the exhaust valve is subjected to direct blasts of exhaust gases of about 1,800 deg. Fah. The only provision heretofore, for radiating the heat from valve head (H) and stem was through the valve guide, therefore the stem often became red hot—result, warping and loss of compression at valve seat.

Principle: The effect of the mercury contained within the valve is of course to transmit the heat from the hottest part of the valve up to the portion of the valve stem, which is exposed to the atmosphere, and which has a series of aluminum radiating fins (F) connected therewith, to facilitate the cooling of the valve.

The mercury (M) under normal temperature is in liquid state and rests at bottom of valve stem—as heat is absorbed by valve stem and transmitted to the mercury, the mercury is vaporized and immediately rises until coming into contact with the cooler part of the valve stem, when it will undoubtedly condense and flow back to the bottom of the stem to again be vaporized and repeat the previous operation.



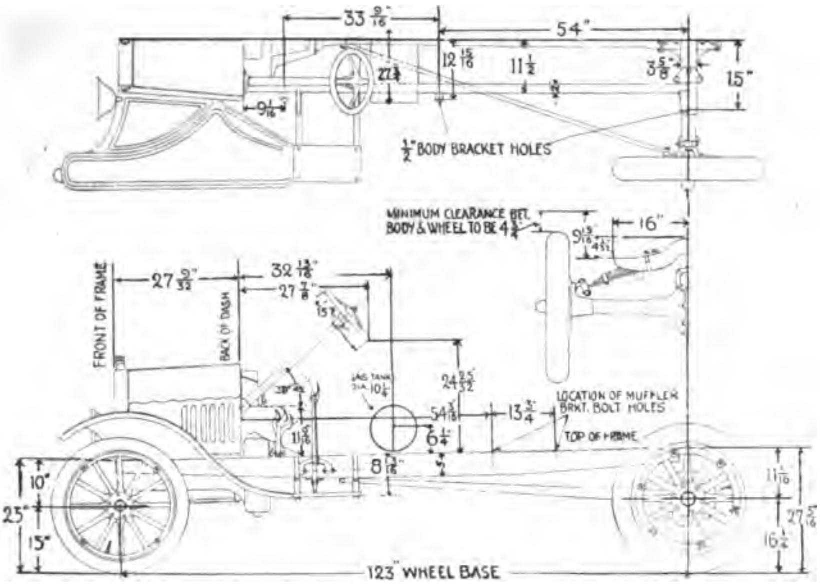


Mercury cooled exhaust valve.

CHART NO. 369A—Miscellaneous Ford Accessories. Delco-Light Plant.

*The Delco plant is well suited for automobile storage battery charging and lighting of garages.

Dimensions of the Ford truck chassis, from which one can estimate dimension for suitable bodies for various purposes. See also, page 821 and foot note page 776.



Dodge Light Delivery.

The specifications are similar to those of the standard passenger car, except that various parts have been strengthened.

The gasoline tank is beneath the driver's seat, and the steering wheel has been set at a higher angle to give a greater loading space.

Maximum load ....1000 to 1500 lbs.
Tires ....33 x 4
Loading space ....72 x 43 in.
Wheelbase ....114 in.
Clutch ....dry plate
Gear ratio ....4 to 1
Body ....steel 54 in. high

Ford Truck.

Engine, with its ignition and carburetion, cooling and lubrication system is the same as the model T —see page 770.

The clutch is the standard Ford multiple disc in oil, delivering the drive to a two-speed planetary gearset in unit with the engine. From here the final drive is by means of a propeller shaft and overhead **worm** instead of a bevel pinion gear.

The ratio in the worm gear is 7.25 to 1, giving a total gear ratio in low of 19.9 to 1, and a total ratio in reverse of 29 to 1.

From the worm the drive transmission passes through the bevel gear differential and semi floating rear axle to the rear wheels.

The Ford truck is rated at 1-ton capacity and has pneumatic *tires in front and solids in rear; it has overhead worm drive.

Wheel base is 123" instead of 100". **Weight truck chassis,** solid tires in rear 1395 lbs.; with demountable rims for pneumatic tires, 1340 lbs.

The springs are the same as those used in the Ford passenger car excepting that they are made heavier in the rear to withstand a great load. This is a transverse type having an arch in the center.

Wheels are wood artillery type. **Brakes, steering gear,** control system, etc. is the same as the model T.

The principal changes are in the **rear worm drive, heavier rear spring and *tire equipment. Tail and side lights** are oil.

Ford Engine In a Boat.

Length of boat suggested 20 to 22 ft. by 5 ft. beam and 1 ft. draft, the latter being for the hull only. The over-all draft or water the boat draws is determined by the size of the propeller. If there are obstructions in the water where boat is to be used, then better fit some form of skeg or protection below the propeller.

In mounting the engine fit strong oak cross-members in the engine compartment and fasten it in place with lag screws using the same brackets fastened to the engine. **Leave the transmission attached** and mount the powerplant so it will be level when the boat is in the water and under way. Boats rise out of the water when traveling fast, so you must make allowance for this. The engine will oil better when on a level. Proper adjustment can be made with shims under it.

The illustration shows a cranking device so the engine can be started from the seat. Arrange to drive a centrifugal or gear pump to force the cooling water around the jackets. Be careful not to get this pump too large, or the engine will be overcooled. Arrange to run some of the overflow water into the exhaust pipe, a foot or more from the engine, which will help to muffle the noise.

It is hard to give specific propeller dimensions, but if built somewhat after the design shown, one having a diameter of 15 in., three blades and a pitch of 22 in. would be about right. (Motor Age.)

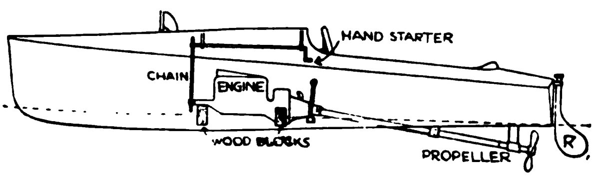


CHART NO. 370—Ford Truck. Dodge Light Delivery. Ford Engine Fitted To a Motor Boat.

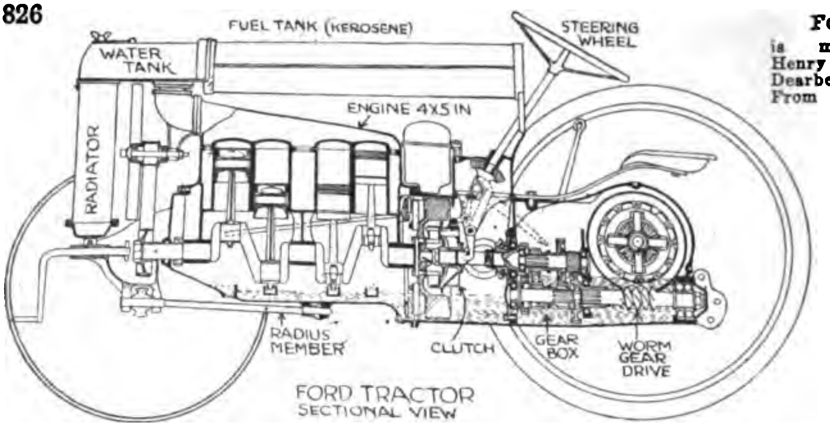
*Ford truck is now $550 with 32x3½ solid tires rear, and 30x3 pneumatic front, or $590 with pneumatic tires 32x4½ rear and 30x3½ front with demountable clincher rims. **Oil in Ford truck differential should be level with upper oil plug.** Mobiloil C, or 600 heavy transmission oil should be used. **Timken roller bearings are now used** in front wheels of Sedans, Coupes and Trucks.

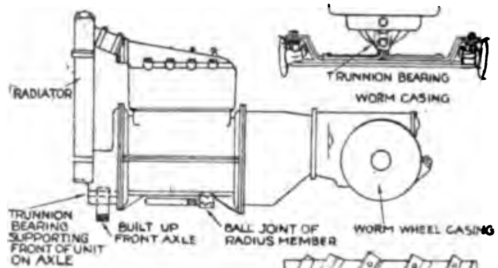


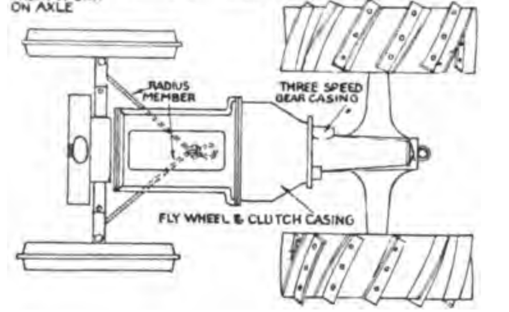
Ford Tractor

is manufactured by Henry Ford & Son, Dearborn, Michigan. From an engineering standpoint the Ford tractor differs and possesses characteristics which distinguish it from others.

The crank case, gear box and axle housing serve also as the frame of the machine. The weight is 2,500 lbs.

Engine—4 cylinder, 4 in. bore by 5 in. stroke. L-head block type, having a displacement of 251.3 cu. in. Delivers 22 h. p. at 1,000 r.p.m. This is with kerosene and at compression of 60 lbs.





Valves: Dia. 1½", lift 5/16". **Timing**: Inlet opens 5/64 to 1/16" after top, distance from top of piston to top of cyl. block being 1/64"; Inlet closes 7/16 to 15/32" after bottom, distance top cyl. to top of pistons 415/32 to 4½"; **Exhaust** opens ¼" before bottom, distance top cyl. to top piston 411/16"; **Exhaust** closes on top, piston being 1/16" above cyl. block. **Valve clearance** .020". See also, page 785 for Ford model "T" engine.

Fuel is carried to an overhead kerosene tank having a capacity of 21½ gallons. For starting, gasoline is used, and a gasoline tank holding 1 quart.

Cooling by thermo-syphon. Water carried in an 11 gallon tank. A four blade fan is used.

Ignition by fly wheel magneto. There are ten magnets clamped to fly wheel which rotate behind the stationary armature.

Voltage of magneto varies with speed of engine from 6 to 14 volts. 14 volts at 1,000 r.p.m.

A high tension coil is used. The timer and distributor are driven by a vertical shaft through mitre gears from cam shaft.

Carburetion is by a Holley vaporizer—chart 372.

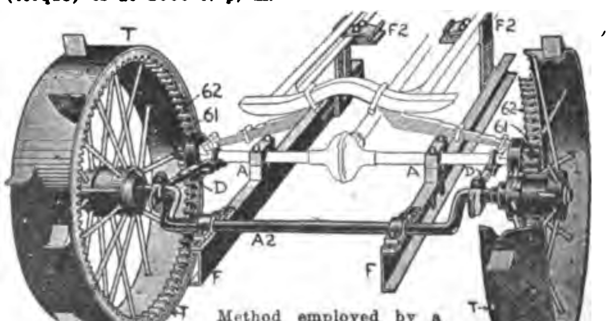
Oiling is constant level splash. Capacity of system is 2½ gallons.

Drive from engine, through multiple disc clutch running in oil. There are 17 tempered steel discs in clutch with face of 11/16". The outside diameter of discs is 7 in. and are held in engagement by six 80-lb. springs, giving total pressure of 480 lbs. Thence through a 3 speed gear type transmission to worm, thence to worm gear on rear axle.

The worm gear is of undermounted type. It comprises a 60-deg., double-thread straight worm having a pitch of 1.2 in. At the rear end the worm shaft is supported in a duplex radial and thrust bearing. The worm is made of chrome vanadium steel and the worm wheel of aluminum bronze, which is composed of 10 per cent aluminum and 90 per cent copper.

The worm wheel is secured to the differential housing by twelve bolts. The differential, which is a four-pinion type, transmits the drive to the semi-floating axle. The driving wheels are mounted on the shaft by means of a slotted, tapered hub filling provided with a flange drilled for four heavy cap screws. The hub piece is splined at the axle connection, to render the transmission of the driving torque more secure.

Tractor speeds: with engine speed of 1000 r. p. m.: **Low speed**, 1½ m. p. h.; second speed (plowing), 2¾ m. p. h.; high speed, 6¾ m. p. h.; reverse, 2½ m. p. h. **Note**: use gear changes to obtain variations of speed. Never run engine above proper speed. The speed can be judged by observing the number of complete turns made by rear wheels in one minute: In low gear, rear wheels turn 12 times; second gear, 22 times; high gear 54 times; reverse, 21 times per minute. **The greatest pull of engine** (torque) is at 1000 r. p. m.



Method employed by a manufacturer for converting a standard Ford model T chassis into a tractor.

Steering is through a bevel gear sector and pinion, with a ball-end drop arm connecting through a large rod to the front axle cross arm.

The driving wheels are 42 in. in diameter and are provided with suitable traction lugs on the rims. The best shape of lugs is one of the details which is engaging the attention of the engineers at present, a self-cleaning lug being the object aimed at.

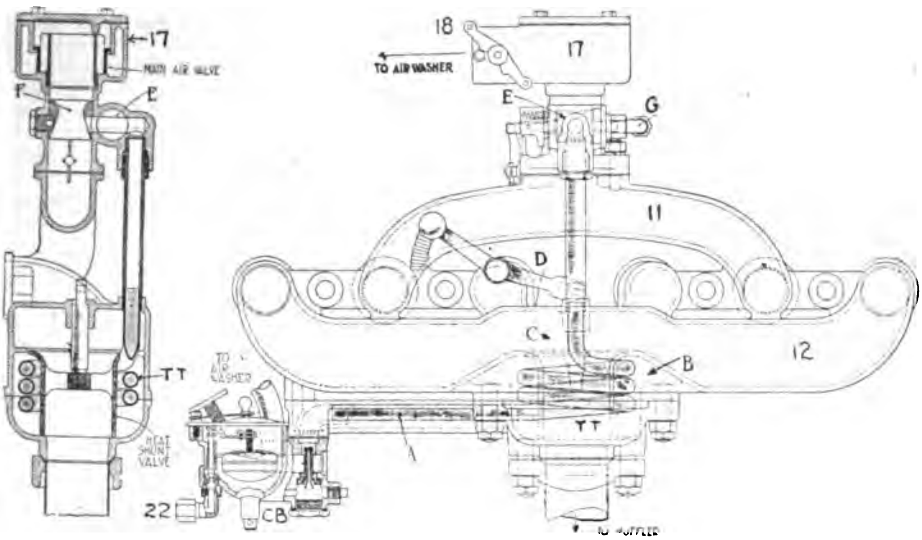
Road clearance is 11 inches. Lowest point being the fly wheel housing.

Crank case can be dropped while tractor is standing on its wheels, only part necessary to remove is the radius rod. Tractor will turn in a radius of 21 feet. **Transmission is three speed and reverse. gear type.**

Do not use model T ignition coil units on tractor engine.

CHART NO. 371—Ford Tractor.

There are two power ratings on the Ford tractor, termed 10-20. 10 h. p. is the draft power; that is the engine at 1000 r. p. m. developes a draw bar pull of 10 h. p. and at the belt pulley the brake h. p. is 20.



***Holley Kerosene Vaporizer.**

The Holley vaporizer puts kerosene into the proper vaporized condition by mixing it with the correct percentage of air to take care of the kerosene vapor after it has been formed, and by means of heat applied in a progressive degree converts this primary mixture of kerosene and air into a mixed vaporous condition.

Heat Is Regulated.

Probably the most notable point of departure of this system as compared with others is the method of shunting the heat, which enables the efficient use of the different fuels under different temperatures.

Another point which should be noted in the Holley system is the use of the thin-walled brass tubing for vaporizing the fuel. This is made as light as it is commercially possible to obtain it, and by means of the rapid flow of heat possible through and around this thin tubing it is possible to use one float chamber and to shift from gasoline to kerosene in from 15 to 30 sec. after starting.

It has been the experience of the Holley company that slight alterations in engine design are necessary for the use of kerosene. The compression can vary from 45 to 70 lb., according to the efficiency of the radiator. On the average engine a compression of about 55 lb. is best for kerosene.

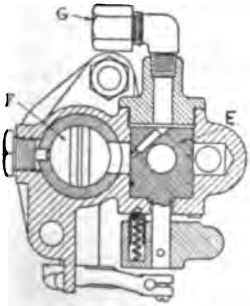
Only One Float Chamber.

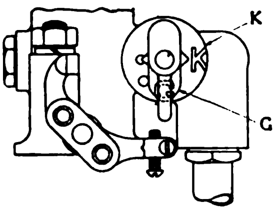
On the particular type to be described there is but one float chamber, and this is for kerosene.

The gasoline for starting is admitted by means of a mixing valve or jet which is only in operation for a short time and which corresponds very closely to the choke tube used on gasoline carburetors for starting purposes.

The kerosene enters the float chambers at (22) and is controlled by means of an ordinary type of float mechanism.

From the float chamber the kerosene passes through an orifice controlled by a needle valve (N) to the top of the jet, where it is atomized by approximately 10 per cent of the total air required for combustion. This action of atomizing is done by the ordinary type of spray nozzle, the air being induced by the suction of the engine.





The mixture of atomized fuel and air is then drawn through the vapor tube (A) situated in the heater chamber of the special exhaust manifold (B), where the fuel is vaporized in its passage through the coiled tube (TT). The relatively rich mixture is heated progressively higher in temperature in its passage through the vapor tube, and by applying the heat at progressive stages, deposits due to decomposition products are avoided.

The temperature of the rich vapor can be regulated by means of the shunt valve (C) controlled by the lever (D), whereby

—continued on chart 373.

CHART NO. 372—Holley Kerosene Vaporizer Used on Ford Tractor.

*See page 831 for Kerosene difficulties and page 754 for other Kerosene Carburetors.

—Holley vaporizer continued.

more or less of the hot exhaust gases can be caused to come into direct contact with the vapor tube, thereby compensating for variations in fuel or operating conditions, such as a cold, wet day and a dry, hot day.

From the heater chamber the vapor tube issues and is connected through the shifter valve (E) to the venturi tube situated in the mixer chamber (F).

Cold Air Dilutes Mixture.

At the venturi tube the rich vapor is diluted with the additional relatively cold air required to form a combustible mixture. In other words, this is the point where the action of the ordinary carburetor is paralleled quite closely, with the exception that instead of gasoline, and air being mixed, a relatively rich mixture of fuel plus 10 per cent of the necessary air is admitted in place of the fuel alone, and in addition the other 90 per cent of the air required is supplied. The additional air required is admitted through a special form of air valve which governs the air admitted in accordance with the throttle position and requirements of the engine.

After the mixture of rich vapor and cold air has taken place the combined mixture passes the throttle into the inlet manifold and thus enters the engine.

The shifter valve (E) performs a double function. In one position it serves for starting purposes using gasoline as fuel, at the same time closing off communication between the vapor tube and the mixer chamber. It is to all intentions a simple two-way valve which, in one position, allows the suction of the engine to fall on the starting generator in communication with the gasoline reserve tank, and in the other position is in communication with the coil vaporizng tube above described.

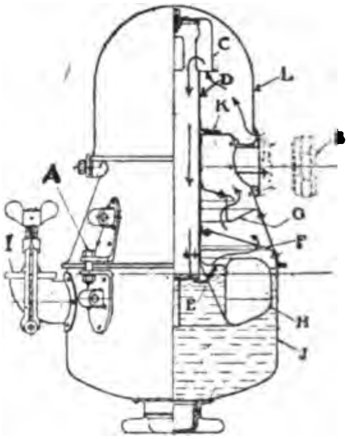
The gasoline for starting is supplied from a small auxiliary tank connected with the connection (G) on the shifter valve housing, passing through the valve into the venturi tube, where it meets the air induced by the suction of the engine in its passage into the intake manifold. The regular running position is, of course, provided when the shifter valve is turned to allow direct communication with the coil vapor tube.

Air Washer.

In England, where this carburetor is in use to a great extent an air washer is employed in connection with the vaporizer. It is a separate and distinct device. The scope of this air washer is to remove any deleterious matter in suspension, such as dust, which is inimical to the engine, from the air to be mixed with the fuel and passed to the combustion chamber. But cars employed in ordinary service, where dust is not generally encountered, at least not in material quantities, need not be fitted with this auxiliary.

The air washer consist of a tank (J) fig. 5 carrying a quantity of water through which the air destined for admixture with the fuel is forced.

The air enters through a tube (D) attached to a float (H), the lower end of the tube being immersed about ¼ in. This depth is maintained by the float, above which is set a number of baffles (FG) to prevent large drops of water passing with the cleaned air from the scrubber. Owing to the cap (C) fragments of dirt are unable to enter the tube, while this cap furthermore acts as an air cut-off valve when the water has fallen low, automatically stopping the engine and warning the driver that the tank (J) requires a fresh water charge. If this cannot be given at the moment, the water filler (I) may be used as an emergency air inlet. Further protection to the upper end of the float tube is assured by the housing (L), so that all air is compelled to pass between this housing and the upper tank at low velocity.



Experience has proved that this wet method of cleaning the air is preferable to all others, because it brings about the complete removal of all dust associated with the air, requires very little power for its operation, is of comparatively small dimensions, and imparts a slight increase of power delivered by the engine when an exhaust-heated carburetion system is employed.

Water consumption naturally varies obviously, being high when low humidity combined with a high-air temperature conditions obtain, and vice versa.

So far as the trials have been carried, it would seem as if the water consumption ranges from 1-10 lb. to 1-20 lb. per horse-power per hour—in the case of a 20 h.p. machine from 1 lb. to 2 lb. per hour—with humidity ranging from 25 to 75 per cent and an air temperature of 80 degrees Fahr.

Since no water leaves the washer in the form of drops, but only in the form of saturation of the air, this water consumption cannot be reduced by mechanical agency. It may be pointed out that the air leaving the washer is not completely saturated.

The washer is applicable to any carburetor, whether exhaust heated or otherwise. In the latter instance no adjustment is required. Test has shown that with gasoline no difference to engine power output is noticeable by the introduction of the washer, it merely overcomes all risk of dust entering the cylinder.

CHART NO. 373—Holley Kerosene Vaporizer—continued. Air Washer.

Another popular Air Washer is manufactured by The Wilcox-Bennett Co., Minneapolis, Minn., and Donaldson Engineering Co., St. Paul, Minn.

INSTRUCTION No. 49-A.

ADDENDA: Additional matter on Tractors, Tractor Engines, Truck Engines and Repairs. Truck and Tractor Engine Ignition. Governors. Motorcycles. Repairing Tops.

Tractor Drive Methods.

This subject was dealt with on page 752. Under this head, additional information will be given on it.

For a tractor to travel over all kinds of roads it is necessary that it lay its own track or road in many instances. Therefore some means of presenting a large surface to the ground on which the weight may be supported, to prevent sinking into soft soil, must be provided. There are several methods employed, the most common being the **flat wheel tread, chain tread and rail track tread.**

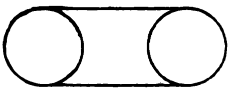


Fig. 1 *Chain tread*

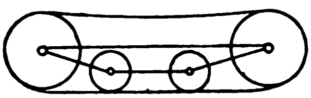

Fig. 2 *Rail track.*

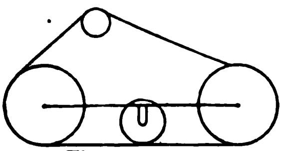

Fig. 3 *semi-rail-track*

The flat wheel tread is the type shown on page 826 as used on the Ford and "Twin City," page 830, and other light tractors. On some tractor wheels the **projecting treads are detachable** and can be removed and deep or shallow treads applied according to the condition of the soil.

The chain tread is furnished by stretching a movable chain of various constructions over and around two wheels, which has the effect of presenting considerable flat surface to the ground between the two points of support. The tread is made to move or crawl by driving the sprocket support wheels which have cogged teeth to engage cogged teeth on the inner face of the chain—see fig. 1.

The above would be termed the chain tread, because the weight of the tractor is supported on the wheels with direct ground contact with the chain tread and minus the rail track.

The rail track tread is represented by the Caterpillar and Cleveland, which differs widely in principle to that of the "flat wheel tread" and differs from the chain tread in that a "rail track" is provided.

The point aimed at by the designers is to secure not merely that the entire weight of the machine shall be evenly supported on the large surface of the chains, but that there shall be no arching of the chains, and that the wheels which do the driving shall carry little or no weight, whilst the wheels which carry the weight not only do no driving at all, but run on **rails** and are not affected by the pull of the chain, and this result is secured in the following manner:

The weight of the tractor is supported on two **axles** or **trucks**, which carry, the one the driving or track sprocket wheel and the other an idle wheel of similar size, and the axles also support **a** beam or connecting bar beneath which are mounted a series of smaller idle or truck track wheels with smooth faces, formed to run on the rails or track.

The weight of the machine is carried on wheels which run on rails or track.

The chain itself, it will be noted, (see **fig** 4), is driven by the track sprocket which is driven by the engine through a countershaft and gear transmission. As the chain tread (also called track link shoes), are made to revolve over the drive sprocket and track idler, then it will be noted, the tractor is really running on rails or a track, which are being laid down for the track wheels to revolve upon.

Although there are numerous methods of design employed for the construction of this chain or outer shoe, as it is termed, the principle is very much the same. **The difference however, between the "chain tread" and the "rail track" tread** is made quite clear in the illustrations fig. 1 and fig. 2.

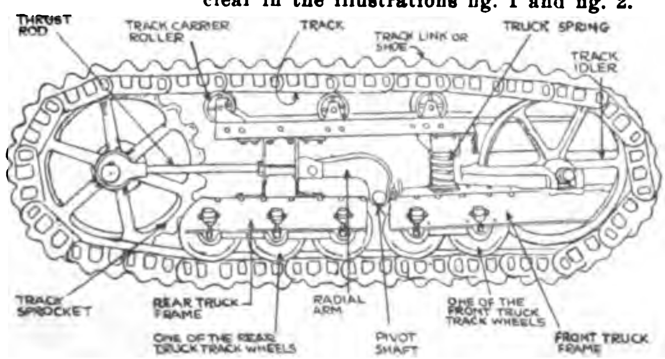

Fig. 4.

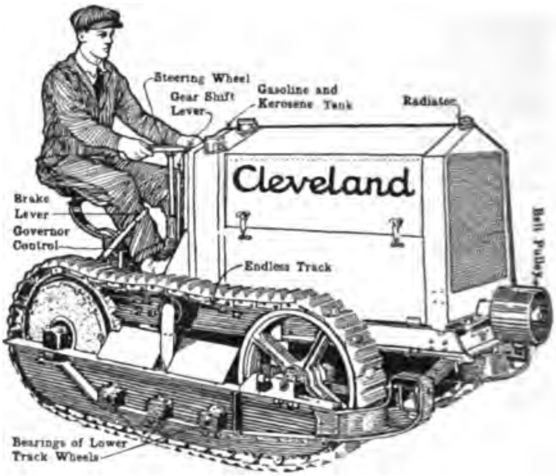
The track-laying portion of a Holt caterpillar. The rear sprocket transmits the drive pulling on the portion of chain which is lying flat on the ground. Weight of tractor is carried by the 5 truck track wheels.

*See also pages 752 and 753.

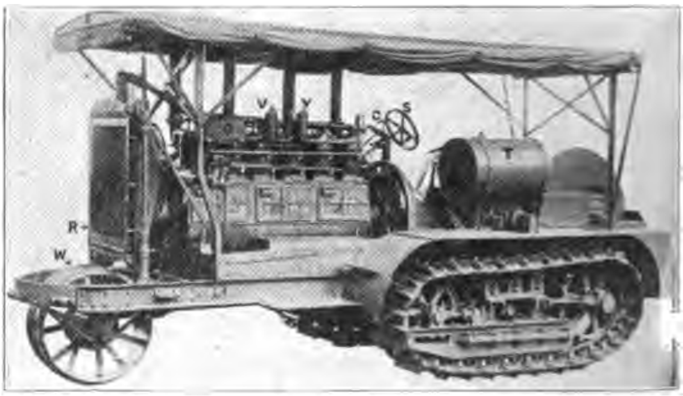
The Cleveland Light Tractor.

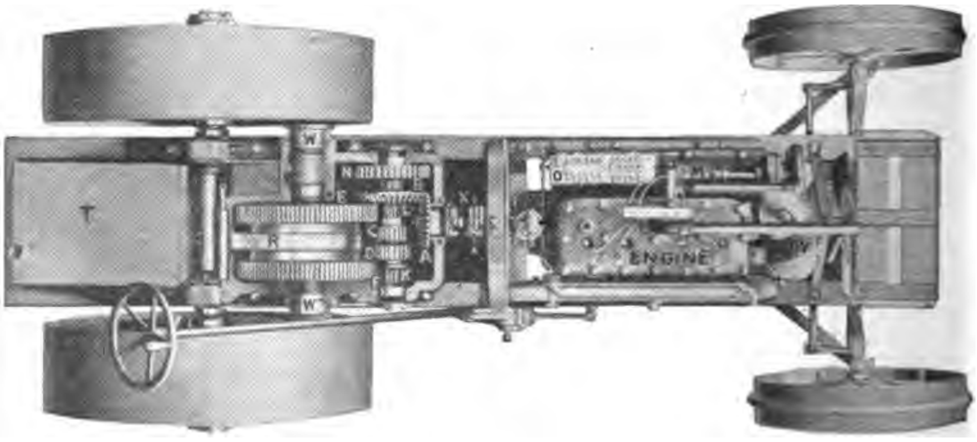
Drive, "rail-track," page 829. **Also termed the "crawler" principle of drive.** See page 831 for description. Note pulley in front for belt power use. Also note driving sprocket is in the rear.



The Caterpillar 120 H. P. Military Type Tractor.

Drive, typical "rail-track," see page 829, fig. 4. Drive sprocket is driven by chains from a countershaft which is driven by a gear transmission and clutch. **Engine,** six cylinder; **vacuum fuel feed** (V) method employed as explained on page 165; gasoline or kerosene is used—fuel tank is (T). A mechanical **oiler** (O), similar to system explained on page 195 is employed. **Ignition** by K. W. **magneto** (J). A throttling type governor for controlling speed of engine through carburetor is employed. In fact the principle of operation of engine is similar to an automobile engine. Access to crank case is through hand hole plates (L). **Steering** by wheel (S) which operates wheel (W). **Radiator** (R). **Spark** and **throttle** control (C).





Tractor Transmission—"Twin City-16" as an Example.

B—is a band brake around drum which contains the differential gears. Belt power is obtained by a shaft (not shown) above and forward, driven from gear (N).

Clutch is the contracting band type which fits over projecting rim (C) on fly wheel page 832. It is operated from seat by shifting clutch yoke (X) above. For **high speed,** (2¾ m.p.h.), the power is transmitted through gear (A), then (B) through sliding gear (D) to (F), thence to bull pinions on end of shafts (W), which drives the internal gear in the wheels. **For low speed** (2 m.p.h.), sliding pinion (O) meshes with (E). **For reverse** (2¾ m.p.h.), power is delivered from (D) to (F) through a floating pinion mounted in the upper half of the transmission (not shown). The floating pinion is also a sliding pinion, so that when in neutral position it is slid out of mesh with gear (F), but continues to run idle with pinion (D) when in neutral (as shown in position (D) is now).

CHART NO. 374—Example of Modern Light Tractors for General Tractor and Belt Use: The Cleveland and Twin City "16." The Caterpillar Tractor.

See also pages 752 and 753.

The Transmission of Power

is usually from engine to clutch, thence to a gear transmission, thence to a countershaft, from which the drive sprocket is driven by a chain. On wheel driven types there is often an internal gear drive in the wheel.

On several new machines a regular truck gearset is employed with three ratios, this being coupled to a jackshaft incorporating a constant large reduction through a pair of spur gears. More than one machine is using a worm gear ahead of the last spur train, so that the worm speed is the same as that of the crankshaft on high gear. There are usually, 2 or 3 speeds plus a reversing gear which allows the different ratios to be used ahead or astern.

Clutches—many are still using the old style expanding or band clutch. The cone or disk clutch is coming in favor.

A clutch lever for throwing out the clutch is used more than clutch pedal, however, many are now adding the clutch foot pedal.

Tractor Engines.

The type of engine used on tractors differs from the regular automobile engine only in a few details. It is constructed somewhat heavier with larger bearings. It runs at a constant speed most of the time, therefore greater heat is developed and more cooling surface is necessary, a governor is employed. Engines for tractor use are usually four cylinder or double cylinder opposed type. Average compression of a truck or tractor engine is 60 to 70 lbs. See also page 753 and foot-note page 832.

Tractor Engine Ignition.

The magneto is generally used with an impulse starter—see pages 832, 255, 277. **Spark plugs** on a tractor engine must be the very best as the tractor engine, unlike an automobile engine, runs for long periods of time at full power and the use of low grades of fuel means higher temperature consequently more carbon.

Kerosene Difficulties.

Kerosene is being used to a great extent, but gasoline is generally used to start on. Very few tractors operate on kerosene alone with any degree of satisfaction.

Kerosene needs more than a heated carburetor—the mixture itself must be heated to prevent condensation in the manifold, as explained on pages 157, 155 and 160. Also see the Holley, page 827.

Where kerosene is used, on account of this condensation, one manufacturer clearly states in his instructions: "If kerosene is used; it will be absolutely necessary that oil in the crank case of the engine be changed after every 20 hours running." This is due to the fact that the kerosene condenses if not properly heated, and mixes with the lubricating oil and thins it down to such an extent it loses its lubricating qualities.

Experiments conducted by the Holley company bear out the fact that once the kerosene has been thoroughly vaporized (heated) and mixed with a sufficient quantity of air to take the vapor by means of heat applied in the proper manner, it is possible to carry the charge several feet without experiencing condensation.

When engine smokes excessively, from the exhaust and smoke is black, then this indicates that the fuel is not being properly combusted, either by feeding too great a quantity at carburetor or not being properly vaporized.

Tractor Steering.

When the three wheel is used—the third wheel is operated for steering.

Where four wheels are used as on the Cleveland, for example; then the steering gear arrangement is as follows; a train of gears are operated by the steering wheel, and these in turn apply a brake to one side or the other of the axle. This slows up the crawler belt of one side of the machine, allowing the other to go ahead at a speed ratio corresponding to the resistance placed upon the opposite member by the brake pressure. When the brake is applied altogether so that one belt or chain crawler is stopped, the reduction is 1½ to ½, or, in other words, 3 to 1, through the differential gears. The actual drive connection between the rear axle and the crawler wheel is by an internal gear. The emergency brake is applied against a band mounted on the outside of the differential drum.

The Cleveland Tractor.

It weighs 2750 lb. and is characterized by its small size, being but 52 in. long by 50 wide. It is rated at 12 hp. at the drawbar and 20 hp. at the pulley, and with its crawler or creeping type of tread, 600 sq. in. of traction surface are provided. The overall length of the tractor is 96 in.

As may be seen from the illustrations the **powerplant** is set well back toward the center of the crawler drive; thus the traction surface carries the weight well toward its center so that a maximum tractive effort can be secured. The **radiator**, which is at the front of the tractor, is the only part projecting forward of the driving wheels, and at the rear the driver is seated slightly behind the rear axle.

The frame of the tractor is made up of two side bars mounted on trunnions at the rear axle, and the crank case transmission and rear axle housings also have their value as structural supports. The effect of three-point suspension is secured by having the rear connections of the side bars mounted on trunnions, and in front these are connected with the cross spring by shackles. This gives a flexible drive which allows the tractor to work at advantage on unequal stretches of ground.

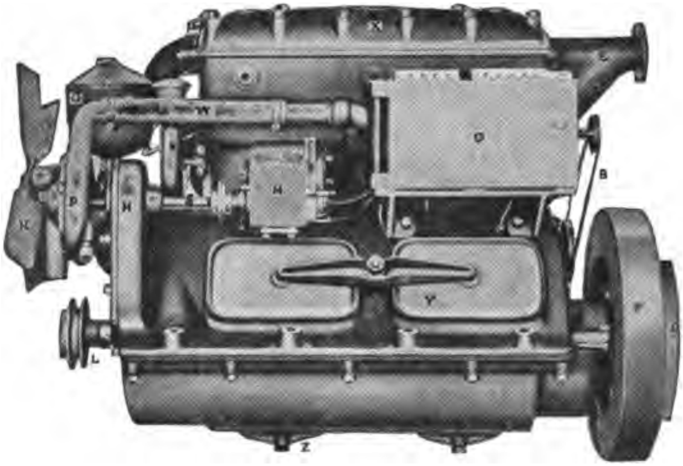
The engine is a Buda model R, 3¼ by 5¼. The characteristics of this engine are such that with the gear ratio used on the tractor an efficient working speed is obtained at 3¼ m.p.h., with a maximum working speed of 4 m.p.h. The revolutions per minute of the engine are 1450 at 4 m.p.h. and 1272 at 3¼ m.p.h.

From the engine the drive is transmitted through a *Borg & Beck dry-plate clutch to a transmission unit developed by the Cleveland Tractor Co. provided with one speed forward and one reverse. The reduction is 25 to 1 in either case. From this unit the drive is transmitted through bevel gears to the axle, which transmits the torque to the crawler mechanism. The belt pulley is 8 in. in diameter and has a 6 in. face. The width of the track is 6 in. and the length, 50 in., giving 300 sq. in. of traction surface on each side of the machine.

The carburetor is a Kingston fitted with a Bennett air washer, the magneto an Eisemann, and the radiator a built-up cellular type. The gasoline tank is mounted just behind the engine and forward of the steering wheel, the latter being mounted upon a vertical steering post with the driver seated on a support mounted at the end of a flat steel bracket which acts as a spring.

*See page 42, 688, 842.

Valve, exhaust and inlet side: C—clutch member on fly wheel (F); K—valve covers; H—carburetor; I—inlet manifold around one branch of exhaust manifold which heats mixture; J-E—exhaust manifold; G—governor—the lever operates butterfly valve in carburetor; L—fan belt.



Magneto and lubricating side: M—magneto, K. W. high tension; S—shaft driving magneto, which is driven by gear in gear case (H); O—force feed lubricator driven by belt (B)—see page 195 for the "mechanical type;" P—water pump; R—breather pipe; Y—hand hole plates to reach bearings, and through which pistons and connecting rods can be removed; G—governor, "fly ball" or "centrifugal" type.

The Twin City "16" Tractor Engine.

Carburetion; gasoline to start on and kerosene, alcohol, distillates of 42° Baume or higher, and flash point of not over 120° F. **Fuel tanks;** kerosene 33 gallon; gasoline 3 gal. A Stewart vacuum system is used, see page 165. **Cylinders;** 4, L-type, 5" base x 7½" stroke. **Speed of engine,** 650 to 750 r.p.m.; **Valves,** on the side; **Ignition,** K. W., model TK, enclosed type.

Tractor Ignition.

Other K. W. magnetos which are used on large tractor engines are models as follows:

Model H—(4 magnets); for engines having normal speed greater than 300 r.p.m., and which have provision for starting or can be cranked at a fair speed by hand.

Model HK—(4 magnets); for use on engines the same as model H, but has the impulse starter for hot starting spark.

Model HT—(5 magnets); for use on engines having normal speed of less than 300 r.p.m., and which have provision for starting with air, etc., and will furnish a hot spark as low as 30 r.p.m. and will fire any sort of fuel.

Model HTK—(5 magnets); for use on engines the same as model HT, but impulse starter allows engine to be started by hand if air supply is lost, or for use on large engines which previously had to be started with battery ignition.

K. W. Impulse Starter.

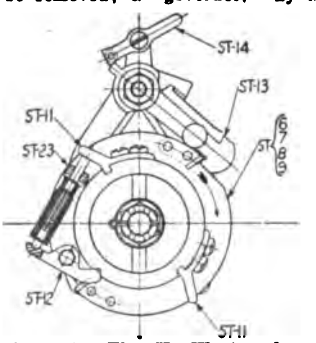


Fig. 10. The K. W. impulse starter is located between magneto drive and armature. When engine is cranked, the armature is held stationary, while energy is being stored in compression spring—which is then tripped.

This attachment allows the engine to be started regardless of cranking speed, as the rotor of magneto (inductor type) is held stationary while the coupling is moving 80 degrees, then is tripped and thrown ahead at the rate of 500 r.p.m., assuring a very hot spark for starting. When engine comes up to speed, the starting device is automatically thrown out of action, and simply revolves with shaft. The magneto is driven at a fixed speed.

To time a K. W. high tension magneto—see pages 288 and 296. **To time with impulse starter:** (1)—place piston 3 to 5° past top center on power stroke: (2)—mount and connect magneto so that the tripping mechanism will not trip the impulse starting device until engine is from 3° to 5° past dead center on firing stroke.

In starting engine up, place circuit breaker in retarded position and press finger down on trigger (ST-14), which releases hook dog (ST-13), so that when ratchet notch on magneto comes around in the right position the hook dog (ST-13) will engage in the ratchet notch, holding magneto back from rotating about 80°, or until engine is from 3° to 5° past top firing center, in which position, if the magneto is properly placed on the engine, the knock-off cams (ST-11) will disengage hook dog (ST-13), thus allowing magneto to jump suddenly forward at a high rate of speed, creating a hot spark in the cylinder under compression, thus firing the engine, no matter how slowly the fly-wheel is turned over.

If these instructions are not clear, then put the ratchet catch (ST-13) out of engagement and time magneto as shown on pages 288 and 296. Cams, see page 298, fig. 9. See also pages 256, 264, 928.

CHART NO. 375—Example of a Modern Tractor Engine. Tractor Engine Ignition—the K. W.

The modern tractor engine differs from the automobile engine; in that it is of heavier construction, long stroke, slower speed governor which throttles the carburetor. Will operate on kerosene or gasoline. With these exceptions the principle is the same. See also page 333, the Waukesha, an engine used on light tractors.

Waukesha 4 Cylinder Truck and Light Tractor Engine.

F—valve spring; D—valve spring retainer; C—valve spring cap; E—lifter adjusting screw; G—lock nut; J—valve lifter; K—valve guide; L—cam on cam shaft; A—valve cap; B—copper gasket; I—valve seat; H—valve face; water circulating pump on left.

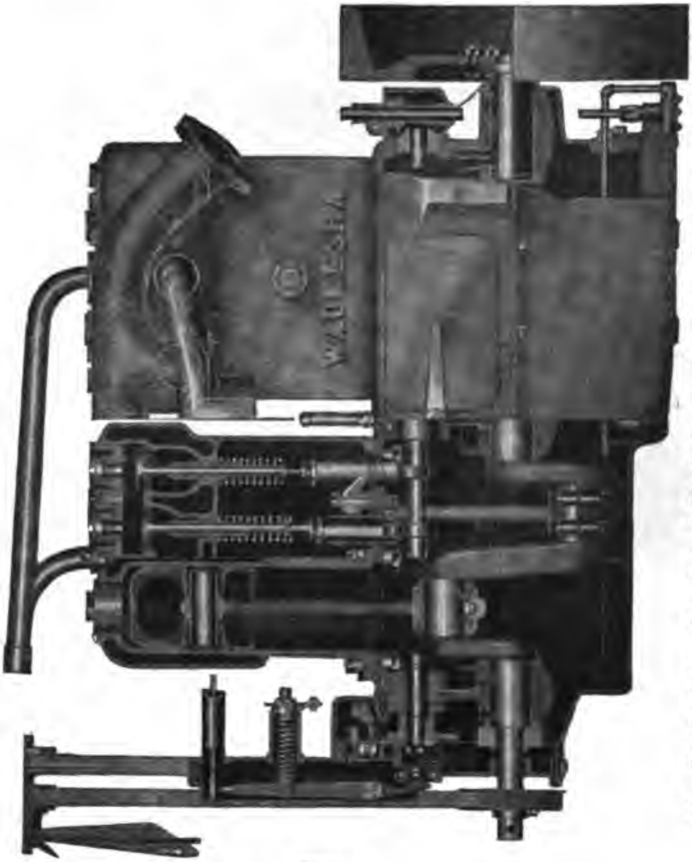

Fig. 2: Sectional side view of Waukesha 4 cyl. engine, showing operation and interior construction. Note governor fulcrum and oil pump, latter being at lower fly wheel end.

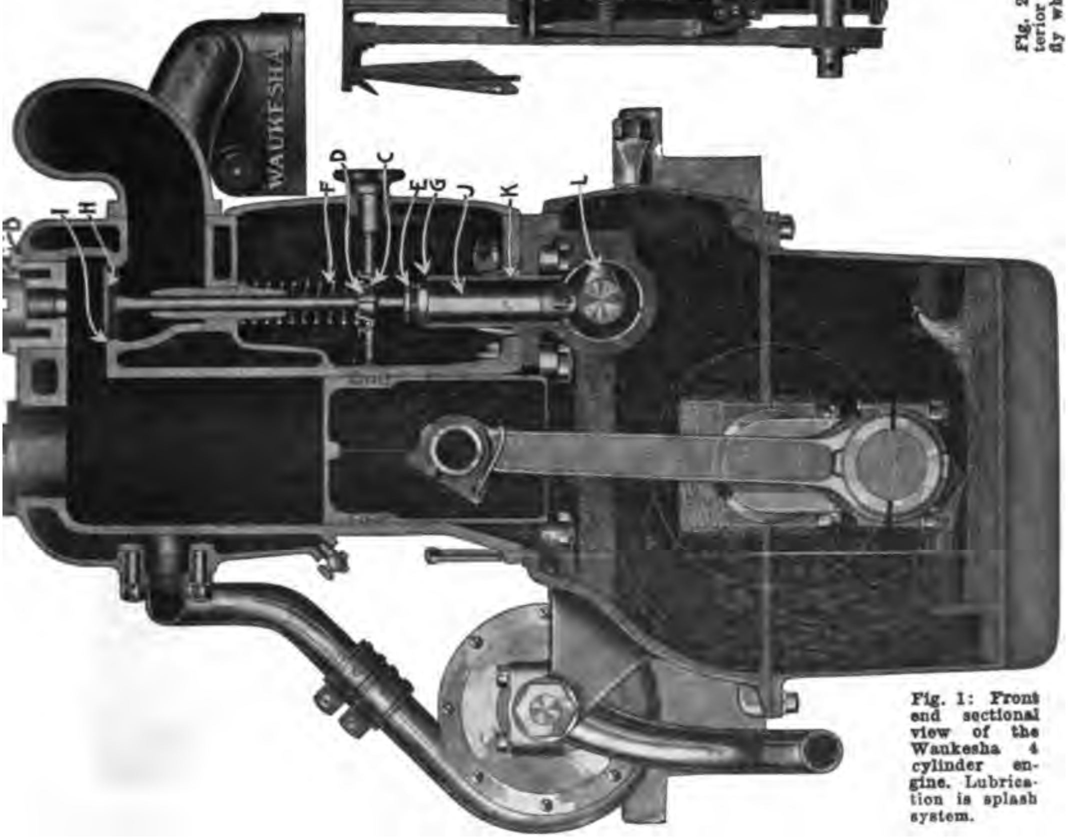

Fig. 1: Front end sectional view of the Waukesha 4 cylinder engine. Lubrication is splash system.

CHART NO. 376—Example of Truck and Light Tractor Engine; The Waukesha. The Waukesha is used on the Gramm, Buford, Chase, Acason and many other makes of Trucks and a number of light Tractors. See also page 71.

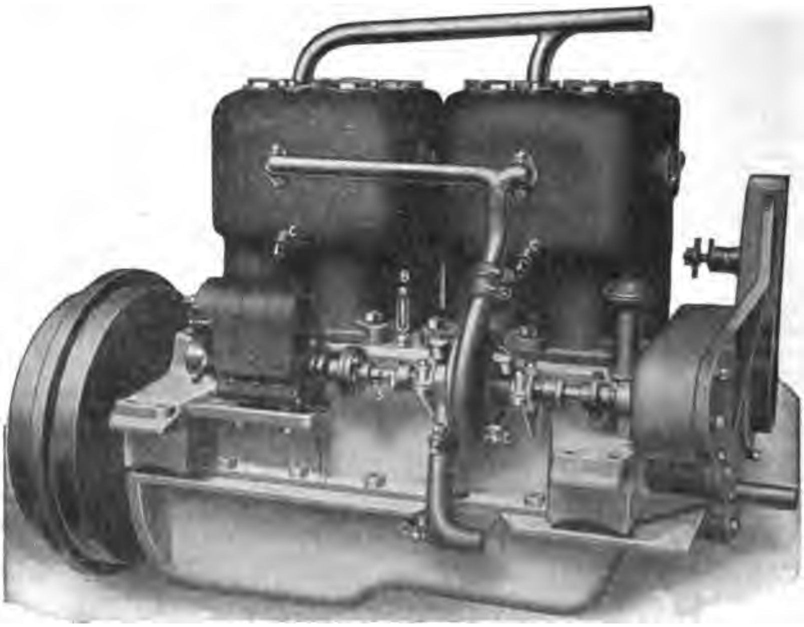

Fig. 3—Right side of Waukesha truck engine—note magneto (also see page 285—type used on this engine. Also see page 312 for setting the magneto). Circulating pump and magneto are driven from gear (O) fig. 5, page 835, also see page 312.

How to Put Oil in Engine.

Remove breather cap (A—fig. 3). Pour oil into breather until needle float in gauge (B) comes up to within ¼ inch of top of glass.

Remove crank case hand hole plate (fig. 6, page 836) and fill each trough under connecting rods.

Use a thinner oil in winter and a heavier one in summer.

C—fig. 2, are water drains for cleaning sediment or rust from water jacket and circulating water pump, also for draining in winter to prevent freezing.

Engine Oiling System Inspection.

Drain oil—remove oil pan so you can inspect thoroughly. When system is running properly a stream of oil is constantly forced through holes A, B, C and D, fig 4. Inspect each oil hole carefully and see that they are not clogged or partially clogged up. A piece of waste or dirt may have worked into one of the holes preventing the entire flow of oil.

To test oil flow; with some oil in oil pan, turn oil pump shaft with a pair of pliers as shown. If the oil discharges through all of the holes then the pump and oil line are o. k.

Clean the screen (S), fig. 4. In fact this should be cleaned often with gasoline, say every 3 months if engine is run regularly every day. When removing for cleaning, be sure to retain supporting spring inside and make sure of an oil-tight joint being established between oil pump screen flange gasket and crank case (see fig. 7, page 836).

The oil pump is located at the lower left side of engine, when in rear of it—see fig. 7, page 836 and fig. 2, page 833. It is driven by cam shaft, see fig. 2, page 833.

Above is oiling system of the models L-M-P-N-R-S-O; SU4R, RU4R, LU4, MU4 and PU4 Waukesha engine.

Kinds of Oil To Use.

Pleasure car; thin. Truck; thicker. Tractor (gasoline); heavy. Tractor (kerosene); heaviest. When kerosene is used clean oil pan often and put in fresh oil—see page 831.

Fig. 4—Oil pan removed.

CHART NO. 377—Caring For and Repairing a Truck and Light Tractor Engine.—Waukesha used as an Example.

To Get At The Gears.

Take off front gear cover carefully. See that no bolts or nuts are mislaid or lost. Also be careful, in taking off the ball-race on the governor, to see that none of the bearings drop out. Do not put the front gear cover on again until you are absolutely sure every one of the ball bearings is in place, and that the paper gasket is in good condition to prevent oil leaks.

Be sure to mark the gears. It is very important that the gears be kept in exactly the same position as when you received the engine. Mark each gear as shown in fig. 5—that is, mark the center gear A-B-C as shown, then mark the same letter on the gear that connects at the particular point. In putting the gears on again see that the connections are A-A, B-B, C-C, just as marked. In marking the gears put the letter on the cog of one gear and on the correspond ing space where this tooth meshes on the connecting gear just as shown in fig. 5A.

Fig. 5—Showing how the gears are arranged. C—drives the magneto and circulating pump; next gear to it is idler gear, placed between the small crankshaft gear B and C; the gear on which governor is attached is the gear which drives the cam shaft and oil pump and is driven by the idler gear also. Therefore cam shaft gear revolves ½ the speed of crank shaft gear.

Operation of Waukesha Governor.

Two circular weights back in the case behind gear "O" fig. 6, are held by—and swivel about—the two pins marked "K." These weights fly out at speed; moving part "A" outward. This action presses the ball bearing thrust contained in retainer "B" outward in proportion.

The lever "D" swivels on fulcrum "C." The movement of "A" causes a movement of rod "R" in direction indicated by arrow. The movement of rod "R" closes valve "H" which is of the butterfly type and swivels on shaft "S."

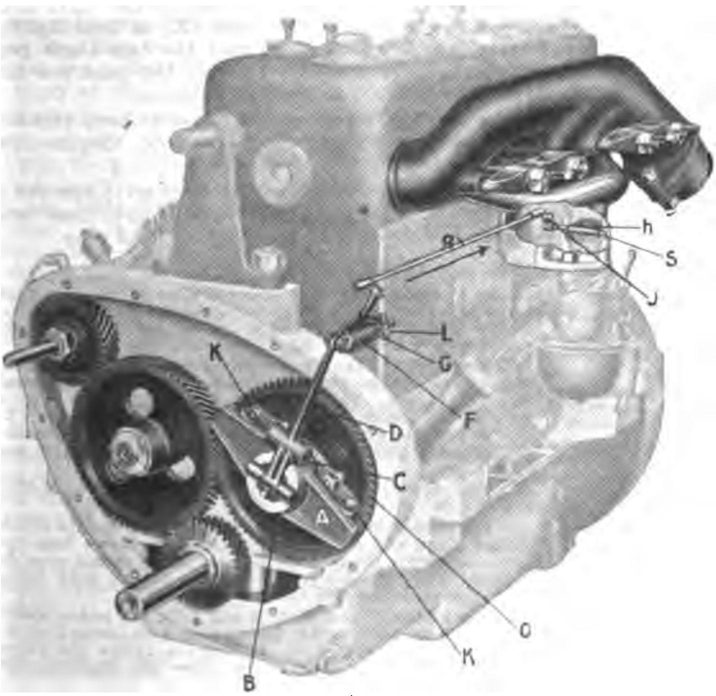

Fig. 6—Front view of engine with gear case cover removed showing gears and governor action. The large idler gear between the two small gears drives the large cam gear and magneto and circulating pump gear.

The adjustment for speed is made by turning screw "L." Turning "L" in direction indicated by arrow causes engine to speed up, while turning "L" in opposite direction causes engine to slow down.

The governor is locked by locking nut "G." It is further possible to lock and seal the whole arrangement by passing a seal wire through hole in spring housing, and through hole in nut "G."

"F" is a spring, the tension of which governs speed of engine. The governor is the throttling type and controls the amount of gas to cylinder—therefore it would be termed a throttling type of governor of the centrifugal type —but by weights instead of balls.

*How to Time the Valves.

All Waukesha engines have cylinders numbered 1-2-3-4 starting at gear end and reading toward flywheel end.

Timing By Fly Wheel Marks.

As a rule the fly wheels are marked as to when the valves should open. The following method is applied in case the flywheel and the timing gears are not marked.

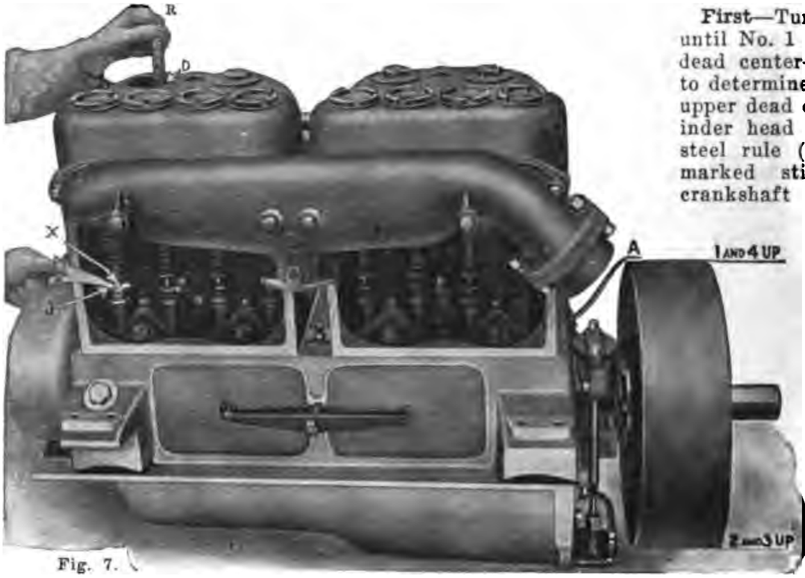

Fig. 7.

First—Turn the engine over until No. 1 piston is on upper dead center—fig. 8. In order to determine when piston is at upper dead center, remove cylinder head plug and insert a steel rule (R) fig. 7, or any marked stick. Rotate the crankshaft and watch while the rule (R) comes up. When it ceases to rise then the piston will be at upper dead center.

Draw two lines across the back side of the flywheel (fig. 8); next measure off 53 degrees on each side of the center line at the lower half of the flywheel.

Second—On the illustration fig. 7, note the pointer (A) (also called a trammel, see also page 105). This pointer points to the exact top center of the flywheel. The arrow on dead center line, fig. 8, shows where pointer (A) points, looking at the back side of the flywheel. Turn the engine over slowly until the arrow (A) points directly on line No. 3 as indicated in fig. 8.

Third—Remove the idler gear (A-B-C, page 835). See that the push rod (J, fig. 7) is in its lowest possible position. Place a thin piece of paper between the push rod (J) and the valve stem (X, fig. 7). Turn the cam shaft gear (see "O" fig. 6), slowly towards the right until the paper which is placed between the push rod (J) and the valve stem (X) is held tightly. Be sure that the valve stem (X) has not raised any. Also be sure that the cam shaft gear retains its position and that the piece of paper is still held tightly between the push rod and valve stem. About .003 to .004" clearance for inlet and .005 to .007" on exhaust.

Fourth—Place wooden wedge between the cam shaft gear and the case to keep this setting. This will give you the free use of both hands to replace the idler gear. Replace the idler gear.

Fifth—Give the engine a slight turn (say about one-half inch on the flywheel); now see if the exhaust valve (X) has raised any. It should, if the above instructions have been carefully carried out. You can now replace the gear case cover and the cylinder head plug.

*Timing by Position of Piston.

If it is impossible to get at the flywheel, remove the cylinder head plug, insert a ruler as shown in fig. 7. When the upper dead center has been determined, measure the distance from the top of the piston to the top of the cylinder. For example, let us say it is 2 inches (see arrow marked D, fig. 7).

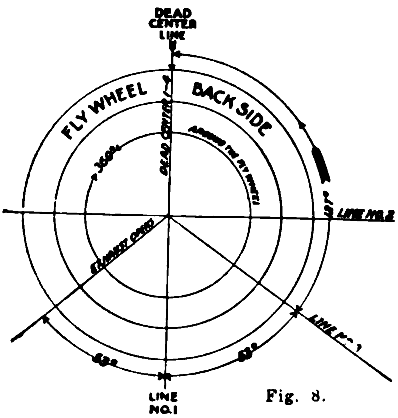

Fig. 8.

Now slowly turn the engine over until the distance from the top of the piston to the top of the cylinder measures 7⅝ inches. This means that the piston has made a drop of 5⅝ inches, at which place the exhaust valve (X) should just start to open. In order to set the valve and complete the timing refer to paragraphs, third, fourth and fifth above.

This setting pertains only to models L-LU4, M-MU4 and P-PU4.

For models O-OU4-OU4R, S-SU4-SU4R, R-RU4-RU4R, N-NU4-NU4R the piston should drop 4⅞ inches from upper dead center, that is the exhaust valve should open 50 degrees before the piston reaches the bottom dead center after the explosion has taken place.

For models T and TU4, B and BU4 the piston should drop 4.644 or 4 11/16 inches from upper dead center; or, the exhaust valve should open 45 degrees before the piston reaches the bottom dead center after the explosion has taken place.

In all events in resetting the valves, the magneto will have to be retimed; for this operation see page 812.

CHART NO. 379—Timing The Valves—Waukesha continued.

*See page 812 for timing the ignition or setting magneto.

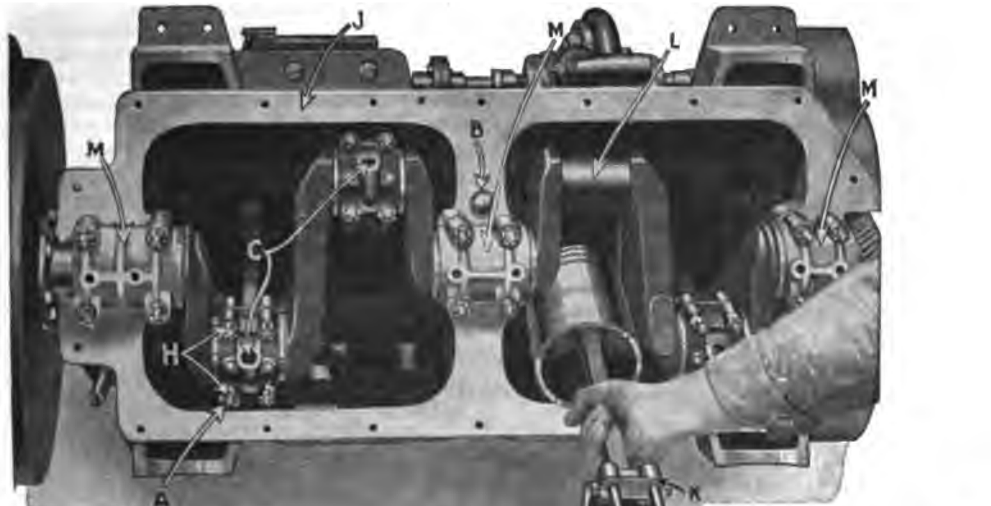

Fig. 9—Showing lower part of crank case with oil pan removed.

Fig. 10—Peeling off a laminated shim, per page 641.

How to Adjust Loose Connecting Rods and Main Bearings of Waukesha Engine.

Connecting rods and main bearings may be adjusted without taking the engine out of the chassis. However, this does not hold true where it is impossible to work at the engine from below.

The following instructions will give you a good idea how to proceed in order to properly adjust the connecting rods and main bearings in many of the modern engines.

First—Drain off the oil by removing the drain or pipe plugs from the bottom of the oil pan; then place a small lift jack under the pan to keep it from dropping before all the oil pan bolts that support it have been removed. It is advisable to tie up the oil float (B) as high as possible to prevent it from dropping into the oil pan while the latter is being removed (this can be done by unscrewing the holder of the oil gauge glass) and thus prevent the possibility of it being damaged or bent. This also makes it easier when you are ready to replace the oil pan. Open all four compression cups on top of cylinders.

Second—After removing pan scrape off the gasket from bottom edge (J) of crank case and clean away all dust and dirt so that it will not get into the bearings. Clean your hands and tools before working on the bearings and never use cotton waste or any rags which might leave shreds behind as these might cause serious trouble to the oiling system.

Third—When working on bearings it is a good plan to pull out the pistons and clean off the rings and piston heads. Always oil the piston rings before replacing the piston.

Fourth—Pull out the cotter pins (A) and unscrew the four nuts (H); (always use a socket wrench for this operation as open end wrenches are apt to destroy the nuts) when taking off the cap be careful not to lose any shims or liners (F) and keep them in place on K, until ready to remove them.

On later engines laminated shims are used between the connecting rods and their caps, allowing one to adjust the bearings to within .002 of an inch. Laminated shims vary in thickness, and are made up of a series of small shims—.002 of an inch in thickness—which are pressed together as one piece. In taking the loose play out of the bearings, one can peel these shims off (fig. 10) to any amount required to have a perfect adjustment on the bearings—never peel off any more of the shims at one time than is necessary. Take out the shims to the amount you think necessary to take up the wear, being careful to remove an equal amount of shims on each side of the cap.

Before replacing the cap, see that the thin shims are placed between two heavy ones with which the connecting rods are always supplied. Replace the cap and draw it up as tightly as possible, using all four nuts and drawing them up evenly and firmly.

Now try turning the engine over by hand in order to find out whether you have the bearings too tight or not. It should turn easily as this represents only one tight bearing; when this bearing is right loosen it, and proceed to fit the other bearings in the same manner.

After each bearing has been fitted and tested draw up firmly all the nuts and use new cotter pins only; never back up the nuts to insert the cotter pins—always draw up to the next notch and never use wire in the connecting rod nuts as it will interfere with the oiling system. Have the cotter pins well bent apart—so they cannot back out when engine runs.

CHART NO. 380—Adjusting Loose Connecting Rods and Main Bearings—Waukesha continued.

How to Replace Worn or Damaged Main Bearings.

First—Take the engine out of the tractor or chassis and before removing pan draw off all the oil. Refer to page 834 for instructions in removing oil pan.

Second—Take out all spark plugs, priming cups, etc., on top of cylinders. Now stand the engine on its head and place props under the engine arms to keep it from wabbling while work is being done.

Third—Remove the oil pan and take out all pistons and be sure that they are all marked so they will be put back into their respective places. Remove gear case as shown on page 835.

It is most important before removing the crank shaft to mark all the gears in accordance with instructions on page 835, otherwise there is a possibility of getting the engine out of time.

Take off the fly-wheel but be sure that you have it marked with the flange on the crank shaft, as it is very important that the fly-wheel is replaced in the same position as when you take it off.

Fourth—Take off the three main bearing caps (M, as illustrated on page 837) and remove the crank shaft. Stand the crank shaft up on end and place it safely aside as a fall might spring it out of shape and later you would wonder why the bearings could not be fitted. Remove idler gear marked A-B-C, page 835.

Take out the screws to remove the damaged bearing. Clean away all dirt and grit with gasoline; fit in one-half of the new bearing in the crank case. This operation is the same as described for replacing connecting rod bearings, page 837.

After bearing has been fitted in the crank case, replace crank shaft. Apply Prussian blue or red lead, to the crank shaft bearing surface and scrape off the "spottings" in the same way as in fitting new connecting rod bearings. Strict attention must be paid that the new bearing does not rest too high in the case so as to throw the other two bearings out of line, nor should the bearing be too low.

Should the bearing be too high, either the other two bearings will have to be raised by shimming them up, or the new bearing must be scraped until the three bearings are on the same level. **The crank shaft must fit the half of the main bearings in the crank case perfectly before you proceed to fit the caps.**

Always fit the rear main bearing cap first and tighten it up as much as possible without stripping the bolt threads. When the bearing has been properly fitted the crank shaft will permit moving with one hand. If the shaft cannot be turned with one hand the contact between the bearing surfaces is evidently too close, and the cap requires shimming. On the other hand, if the crank shaft moves too easily some shims must be removed to permit it to set closer.

After removing the cap observe whether the blue "spottings" indicate a full bearing the length of the cap. If they do not the bearing will have to be scraped. Lay the rear bearing aside and proceed to adjust the center bearing in the same manner. Repeat this operation with the front bearing, with the other two bearings laid aside.

When the proper results have been obtained with the bearings replace the idler gear and be sure that the connections A-A, B-B, C-C, correspond, as shown in cut on page 835.

You can now replace the caps and insert the cotter pins, or wire. **Be sure when you replace pistons** that the heads and the rings are free from grit and carbon, also oil each piston ring carefully.

Fifth—Oil the bearings well by means of an oil can and turn the engine over (by using the crank handle) several revolutions before replacing the oil pan.

Sixth—Are you sure that holes (C) in all four connecting rod bearing caps are facing direction engine runs? This is important because when the engine runs oil is forced into these holes to lubricate the bearings; if one of these holes should face in opposite direction that bearing would get practically no oil the bearing would heat up and soon cut out resulting in a costly repair.

Seventh—Refer to oiling system page 834, before replacing pan.

How to Replace Worn or Damaged Connecting Rod Bearings.

First—Remove oil pan as instructed on page 834; then take off the cap and pull out the piston as shown on page 837.

Second—Take out the screws (D) in order to remove bearing (E). Be sure to fit the bearing half with the large oil hole (S) in the cap, and the other half in the connecting rod (K).

The back side of the bearing must have a perfect or snug fit in the connecting rod, otherwise it will be impossible to get a perfect permanent bearing on the crank pin (L). Fitting the back of the bearing is practically on the same order as fitting the bearing to the crank pin. Using Prussian blue or red lead in the rod and cap will enable you to find the high spots between the cap and the bearings; these high spots must be draw filed—see pages 630 and 643.

Third—Put in the screws (D) very firmly and be sure that the heads are lower than the bearing surface so that they do not come in contact with the crank shaft. Next draw file across the top of the cap and the rod to have the bearing flush with same.

Fourth—Without replacing the piston in the cylinder fit the bearing to the crank pin (L); if the bearing is too wide the ends will have to be draw filed. Be careful not to file too much off. By applying Prussian blue or red lead to the crank pin surface it will enable you to fit the bearing to the pin to determine whether a perfect bearing surface is obtained. Remove the rod and observe whether the blue or red "spottings" indicate a bearing the full length of the cap. If they do not the babbit should be scraped until a perfect bearing surface is obtained.

Adjust the bearing to the crank pin so it can be moved to and fro freely, but at the same time it must not be loose. **Remove the connecting rod and replace piston and give the bearing the same adjustment as you did when the piston was out**; then turn the engine over by hand several times to make sure that no binding takes place.

Do not be afraid of getting the connecting rod bolts too tight as the shims under the cap will prevent the metal from being drawn into too close contact.

Governors.

Governors are extensively used on trucks, tractors, taxicabs, marine and stationary engines.

Purpose of the Governor.

There are two reasons for using a governor; one, to regulate the vehicle speed, the other to regulate the engine speed. Where it is desirable to limit only the vehicle speed of trucks, taxicabs, or even pleasure cars, the transmission or front wheel type of installation (fig. 1, page 840) is used. The governor is set at whatever speed the car owner desires, is then sealed and the driver can never exceed the speed for which the governor is set. The engine type of governor (fig. 2) is used to prevent undue racing of engine when changing gears or releasing the clutch. The average driver will work his engine at high speeds a great deal more than necessary, straining the entire mechanism of the car, and wasting both fuel and oil. By governing the engine speed, the vehicle speed is also limited.

Drive Methods.

Transmission drive—(fig. 1, page 840): With many models of trucks, taxicabs, fire apparatus and pleasure cars, it is more desirable to control the vehicle speed than the engine speed, thus leaving the engine absolutely unrestricted at any speed, except when in high gear. When this is done, the governor (G, page 840) is driven by means of a flexible shaft and tube (SH), and gears (K) (L) attached to transmission shaft or front wheel.

Engine drive—fig. 2: This type of governor regulates the number of revolutions of the engine, and will keep it running at a definite, safe speed regardless of the load it is pulling, even if the throttle is wide open. The regular **hand throttle lever or accelerator may be used for lower speeds.** Should the clutch be suddenly released when engine is pulling a load or running at maximum speed, the engine positively cannot race. The engine governor **also limits** the vehicle speed, because the engine cannot exceed the set speed.

Dual drive—fig. 4: To provide double protection the engine drive and transmission drive governor have been combined. When driving in high gear, only the vehicle speed will be controlled, but when the vehicle is stationary, or being driven in low gear, the governor throttle valve will close before a damaging engine speed is reached. The engine governor is set at a higher speed than when used singly. The most popular use of the dual type is for controlling the engines of fire trucks, army searchlights, etc., where the engines perform two kinds of work.

Care and Installation of Pierce Governor.

Mounting governor. Use thin gaskets of blotting paper only. **Don't use shellac**—it will cause the governor valve to stick.

Flexible drive shaft. There should be no bends in shaft within two inches from either end, nor should shaft be bent into a circle of less than ten inch radius. Make all bends as easy and large as possible.

Solid drive shaft. In mounting solid shaft, be sure that shaft ends properly engage in governor, right angle drive, and engine connection, lock nuts on tube are tight. Don't screw tube up tight enough to cause shaft or gears to bind.

Oiling governor equipment. Before the governor is put into active service, see that the case contains about four ounces of good light oil (light Polarine preferred) that is not affected by change in temperature. Put in one or two ounces of oil every thousand miles. Flexible shaft should be kept packed with Artic No. 3, or a good graphite grease, renewing same every two thousand miles. Oil gear bearings, right angle drives, or engine connections, each week through oil holes provided.

Loose connections. When driving gears or brackets are used, examine them regularly to see that none work loose and that gears are kept in perfect alignment and meshing properly. If a belt is used, keep it tight and free from oil or grease, to prevent slipping.

Regulating governor speed. Should it be desirable to change the speed adjustment, cut the wire that seals the adjusting screw and pull off the cap that it holds in place. The adjusting screw (A, fig. 3) will then be exposed. Turning this screw to the right or clockwise decreases the speed; turning to the left or anti-clockwise increases the speed. When proper adjustment has been made, replace cap and seal same, so that the adjustment cannot be tampered with or affected by vibration.

Note: The governor does not interfere with the regular spark or throttle levers, or with accelerator control by hand or foot—see paragraph "engine drive" above.

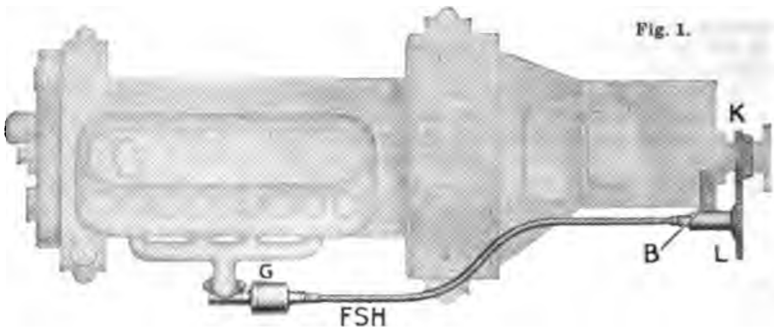

Fig. 1 — Governor (G) is driven from transmission, through flexible shaft (F. S. H.) and gears (K and L). Bracket (B) supports driven gear (L). Could be driven from front wheel.

Governor controls vehicle speed only, leaving engine free, except when high gear ratio is used.

Operation of Pierce Governor.

The governor valve box (fig. 2) is mounted between the carburetor and intake manifold and connected to the driving shaft by means of either a solid shaft (SSH-fig. 2) or a flexible shaft (SH-fig. 1), depending on type of installation.

Normally the butterfly valve (V fig. 3) is in a position that does not obstruct the flow of gas, but it closes so as to reduce the valve port area just as soon as the vehicle or engine reaches the predetermined speed. The valve is actuated by what is known as the flyball or centrifugal principle. On the controller shaft are two weights (W, fig. 3) which are so pivoted that as the velocity of the shaft increases they are swung outward, forcing a plunger (P, fig. 3) forward, which in turn closes the butterfly valve (V, fig. 3). The plunger is forced against a spring (S, fig. 3), calibrated to a standard pressure, so that as the speed is lessened the weights return to their original position and valve is again wide open.

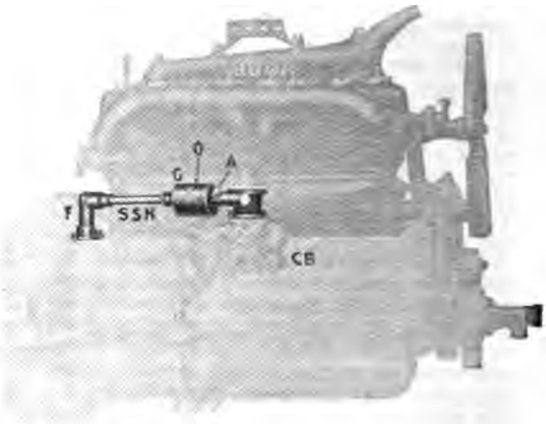

Fig. 2—Engine speed controlled by governor (G) driven from gear on cam-shaft through adapter (F) and solid shaft (S. S. H.). O—oil cup; A—adjusting screw and seal. Governor can be driven from any rotating part of engine.

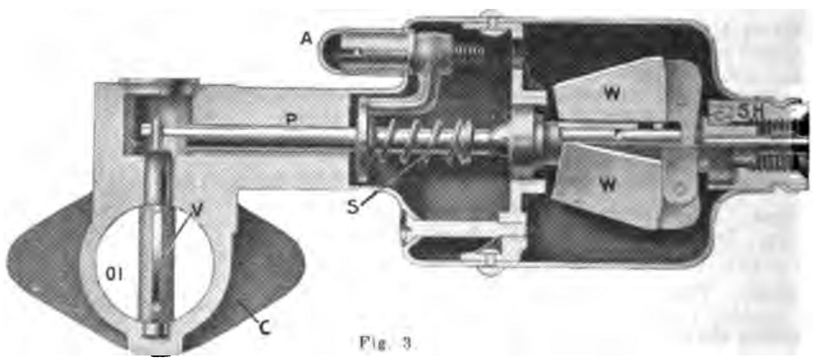

Fig. 3 — Cross section of Pierce governor; C—connects between flanges on inlet manifold and carburetor; OI — is passage opening for gas; V—butterfly valve; P—plunger operating valve bell crank; S — spring; A — screw for adjusting spring tension; W—centrifugal weights; SH—where driving shaft connects.

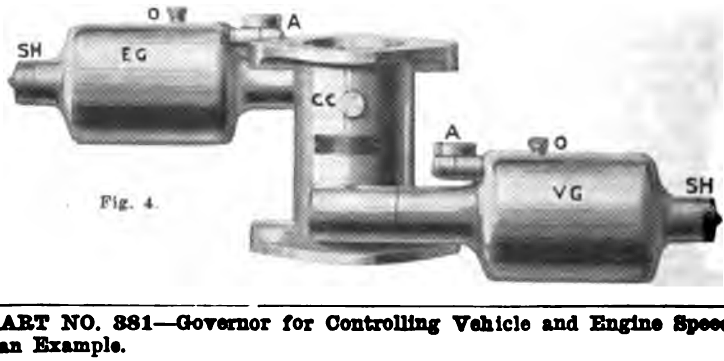

Fig. 4—Pierce dual purpose governor. EG—engine governor; VG—vehicle governor; CC—connects between carburetor and inlet manifold; SH—where driving shafts connect; O—oil cups; A—adjusting screws and seals.

CHART NO. 381—Governor for Controlling Vehicle and Engine Speed or Both. Pierce Governor as an Example.

See text page 839 for further explanation.

The Simplex and Duplex Governor.

This governor, fig. 10, is placed between the carburetor and intake manifold. It operates on the centrifugal principle. As the speed increases, the weights W, cause the valve (T), which is of a grid construction, to gradually close the gas passage (G0 & G1), thereby cutting off the flow of gas to inlet manifold. Therefore it would be termed a "throttling type governor; centrifugal type."

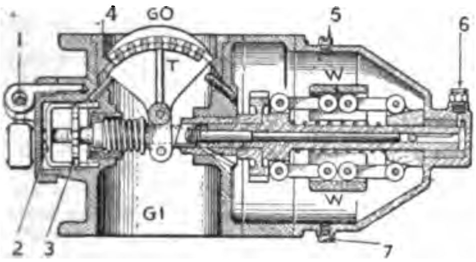

Fig. 10—The Duplex Governor.

1—Locking pin.
2—Yoke.
3—Hand wheel.
4—Valve seat.
5—Oil entrance.
6—Oil cap.
7—Oil discharge.

On the Simplex single drive governor, the shaft is attached to engine or vehicle as may be desired.

On the Duplex double drive governor, one shaft is attached to the engine and the other is attached to the vehicle, at the wheel or transmission.

The difference between Duplex and Simplex is that with the former you can control both the engine and vehicle speeds, whereas with the latter, either the engine or vehicle speeds can be controlled.

On high gear a truck running at 12 m. p. h., the engine may only turn over at 900 r. p. m., but for low gear service the engine may be governed for 1400 r. p. m. Therefore, you would be able to maintain 12 m. p. h. even in second gear.

The governor is a telltale on carburetion If it surges it may result from one of five causes: The mixture is too rich; governor lubrication is bad; the ignition is faulty; the governor valve is dirty; or the cable drive is not steady and free from backlash.

To Set and Care for the Simplex or Duplex Governor.

To set: First get consent of factory, otherwise you may lose your guarantee. Turn the hand wheel (3) out for higher, and in for lower, speeds. Do not fail to lock the hand wheel with the yoke (2) after setting, if a locking spring is not provided, and see that the yoke does not bind on hand wheel. The locking pin and seal (1) are for the protection of the governor and the engine. Do not touch the valve screws (4).

To operate engine with a governor, for best economy; run vehicle on governor speed as much as possible. Bring vehicle speed up to set maximum governor speed with throttle lever and then advance spark and throttle to the best normal running positions.

Don't over advance throttle, as engine might "hunt" with heavy load on low piston speed. Find the best throttle position and mark it.

Lubricate weekly at (5) by filling chamber with medium cylinder oil, 600-W preferred for summer, and in winter add equal amount of light machine oil. Every 1000 miles remove drain (7), fill half full of light machine oil, run for 10 minutes to clean interior and drain out. Then refill as above.

To clean governor valve—if necessary, pour kerosene into air inlet of carburetor while engine is running, varying the speed.

McCann Suction Type Governor.

This governor is mounted on carburetor as per fig. 12, page 71. When engine is turning slowly, the full current of gas from carburetor, as controlled by throttle, is allowed to pass to cylinders. As speed increases, resulting suction causes piston (P) to rise against pressure of spring (S), thus gradually cutting off supply of gas through perforations, until at maximum speed-setting engine cannot be further accelerated.

FIG. 27

The Monarch Governor

differs from the Pierce and Simplex, in that **the speed of the ingoing gas is utilized as the motive power for operating the disc** or control member (A)—see page 842.

There are no connections to any moving parts of the engine or vehicle. Neither are there revolving parts as centrifugal weights or balls.

Location of governor is between the carburetor and the inlet pipe. When installing, the adjustment is made when a change in the maximum speed of engine is desired. See page 842 for construction and operation and adjustment. The manufacturers are Monarch Governor Co., Detroit, Mich.

Operation.

When the engine is started and the throttle is in wide-open position the speed of the gases lifts the disc "A" in the tapered chamber "B" to a position the height of which is determined by the amount of spring tension, and it is held in that position by the speed of the gases while the engine is running, and so the throttle "F" is held in a corresponding position, limiting the supply of gas.

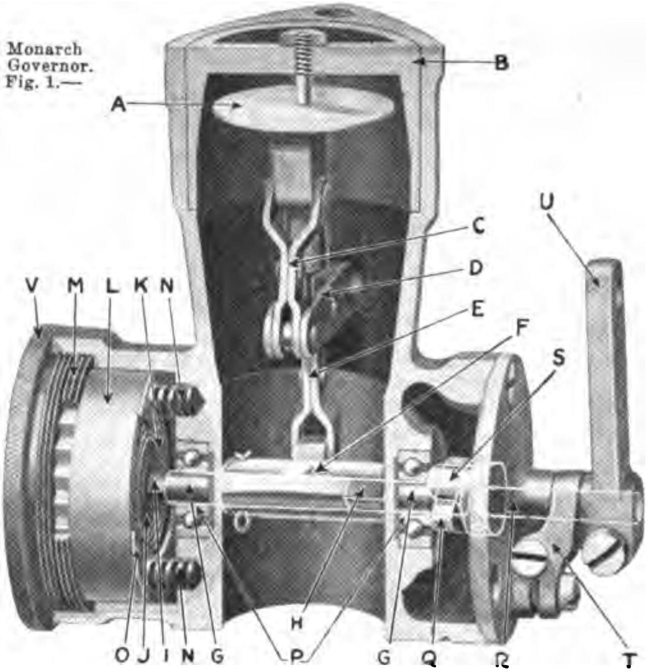
Anything which tends to decrease the speed of the engine, namely, going up hill, through a mud-hole or additional load added, in turn causes a decrease in the speed of the engine and a consequent decrease in the speed of the gases, when immediately the disc drops and opens the throttle to admit a sufficient amount of gas to maintain the speed at which the adjustment was made

—continued on page 842

*Pierce Engine Governor Co., Anderson, Ind. **Duplex Engine Governor Co., 86 Flatbush Ave., Extension, Brooklyn, N. Y.

—continued from page 841.

Monarch Governor. Fig. 1.—

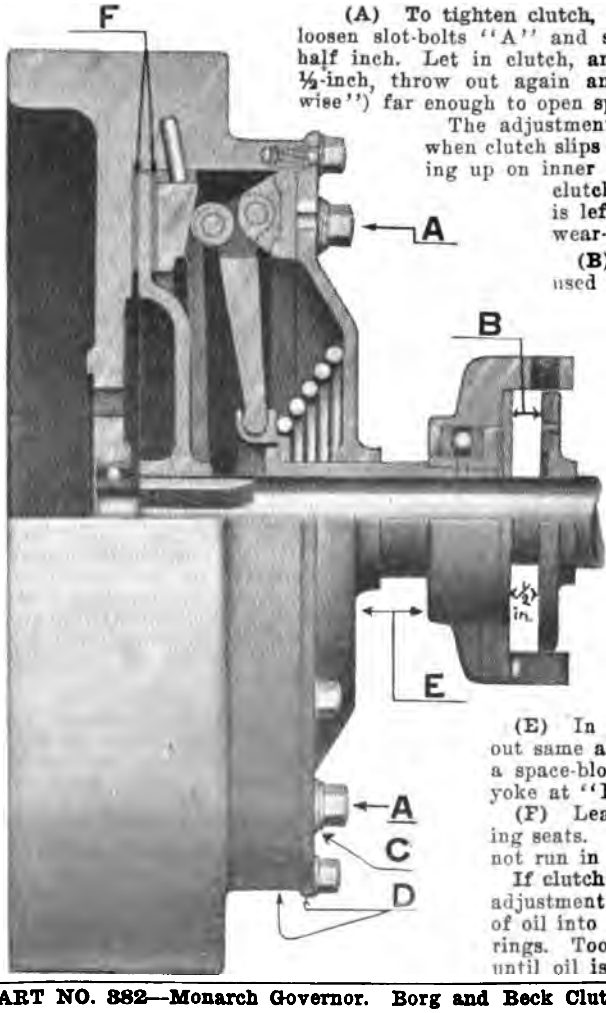


before the additional load was added. The same is also true when the engine is instantly relieved of its load; the speed of the gases increases and raises the disc to the position required to maintain its fixed maximum. It is therefore evident that, an adjustment of spring tension made to produce a certain engine speed, that speed will be maintained regardless of load.

Adjustment.

To adjust the governor to produce any required engine speed, remove the lock and lock pin, unscrew the cover "V," push in on the finger boss on the spring housing "L," and turn in the direction indicated by the arrows "Fast" and "Slow" to increase or decrease the speed, always being sure that the control lever is in a wide-open position when the adjustment is made; and be sure that the cover "V," the lock pin and lock are in place before the truck is put in service.

Adjustment of the Borg and Beck Clutch—See also Pages 42, 668.



(A) To tighten clutch, first "release" with foot lever, then loosen slot-bolts "A" and shift same "clockwise," about one-half inch. Let in clutch, and, if opening at "B" is less than ½-inch, throw out again and tap slot-bolts back ("anti-clockwise") far enough to open space at "B" to full ½-inch.

The adjustment "A" also adjusts foot pedal, and when clutch slips it is usually due to clutch pedal hanging up on inner side of foot board. When adjusting clutch see that at least ½-inch clearance is left between pedal and foot board, for wear-in.

(B) The adjustment at "A" must be used to increase or decrease this "B" space. When clutch is "in," if space between these brake faces is less than ½-inch, the throw-out movement will be too short for clean release.

(C) If bolts "A" adjust against last end of cover-slots, screw them out of their mounting-holes and set them back into repeat holes exposed near first end of slots, thus doubling the range of adjustment.

(D) If, for any reason, the clutch is to be taken apart, first punch remounting "line-up" marks on cover and casing, as clutch will not work properly if cover is shifted in remounting.

(E) In taking the clutch apart, first throw out same and "lock-out" the spring by placing a space-block between the cover and throw-out yoke at "E."

(F) Leave asbestos rings loose in their working seats. Do not fasten to the metal parts. Do not run in oil.

If clutch does not work smoothly take out one adjustment screw and squirt about three spoons of oil into same, just enough to moisten friction rings. Too much oil will cause clutch to slip until oil is burned out.

CHART NO. 382—Monarch Governor. Borg and Beck Clutch.

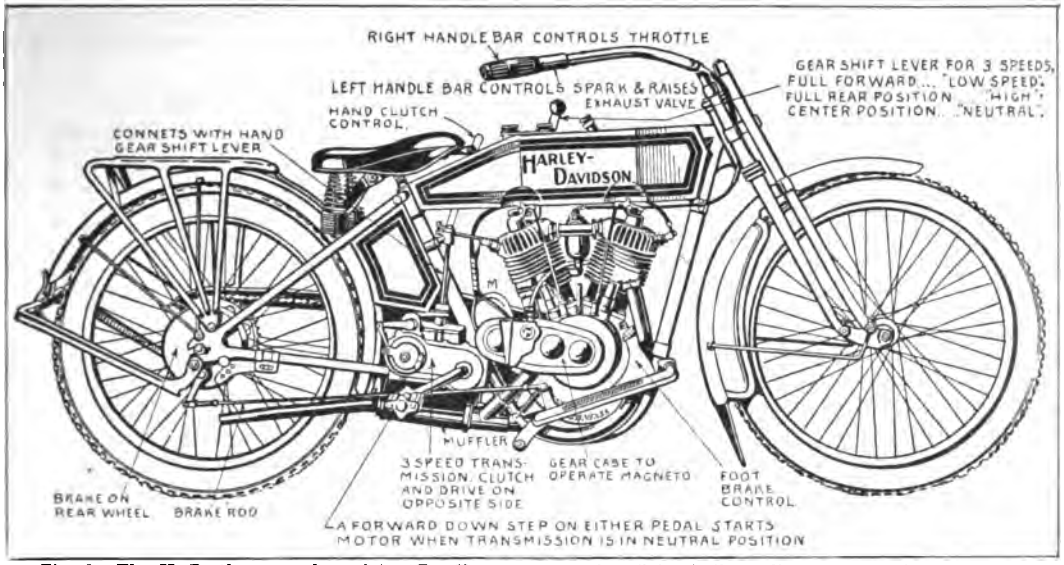


Fig. 2—The H. D. three-speed, model 11F. The 1918 model 18F is similar. The gear box is mounted to the rear of engine on the frame. Note lettering on illustration.

To start the three speed model engine, shift gears into "neutral" position and have clutch "in;" start engine by pedal. After engine is started release clutch. To start machine place gears in mesh, starting off on "low," gradually applying clutch. The Remy electric system below, is used on this type of machine and is then called model 18J.

**The Remy Lighting, Generating and Ignition System—1915 Model.

The generator is driven by the engine. The shaft being connected to engine. The armature of generator is a drum wound type mounted in the upper portion of the generator. Current is "direct."

The generator is connected with a 6 volt storage battery as shown in fig. 6. The generator supplies current for lamps, horn and ignition, the surplus current being stored by the battery. The battery then supplies current to the lamps when the engine is not running.

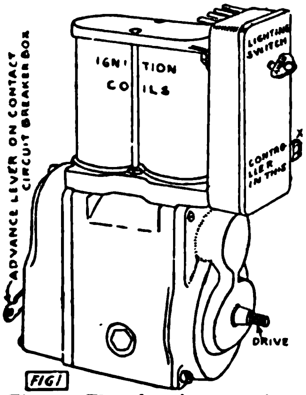

Fig. 1—The electric generator with ignition breaker box, vacuum controller and ignition coils all in one unit.

The lighting switch has three positions; off, bright head and tail lights, dim head and tail lights.

The ignition (direct current) is taken from battery to start on and generator, after generator is running. The current is carried through a circuit breaker on lower end of the generator. This circuit breaker is similar to a magneto circuit breaker and has a lever for advancing.

The current is carried to coils of high tension type without vibrators, mounted directly over generator. This low tension current, which is 6 volts, is interrupted at the proper time being transformed into high tension current through the secondary windings of coils. A distributor carries the current to the spark plugs.

***Vacuum controller is located in the switch case and is connected through a check valve (X, fig. 3) to the engine intake manifold by a small pipe. When the engine is turned a fraction of a revolution for starting, either by the step starter or by pedaling, a vacuum is created in the intake manifold which in turn acts upon the controller, drawing the contacts (C, A, fig. 3) together, and thus connecting the generator, horn and ignition to the battery and holding this circuit closed until after the engine has stopped running for a few seconds. The purpose of this device is to automatically cut off the connection between battery and generator.**

In reality it is a "cut-out" for the purpose explained on page 384. A separate switch for ignition is not necessary as the ignition current is taken from battery to start on.

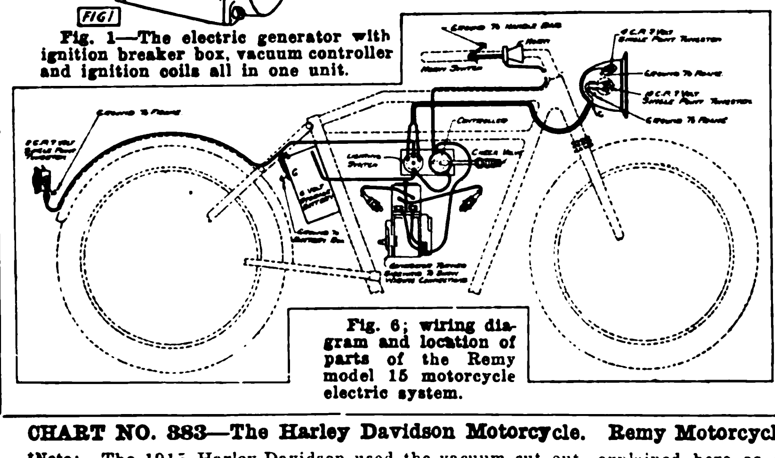

Fig. 6; wiring diagram and location of parts of the Remy model 15 motorcycle electric system.

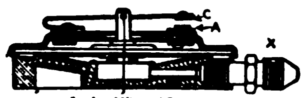

Fig. 3 — Sectional view of controller.

CHART NO. 383—The Harley Davidson Motorcycle. Remy Motorcycle Electric System.

*Note: The 1915 Harley-Davidson used the vacuum cut-out, explained here as a matter of information. Later **models used the mechanical governor principle of disconnecting and connecting the battery, similar to the mechanical cut-out explained on page 811. Model 18-E is a direct geared (no transmission); 18-F, has 3 speeds and uses a magneto (Dixie or Berling) for ignition, no electric system; 18-J—has 3 speeds and uses Remy** electric system with coil and battery ignition. See insert No. 3 for H.-D. engine. ****Reason for showing the older model of motorcycle** is due to the fact that the older models are those more likely to need repairing.

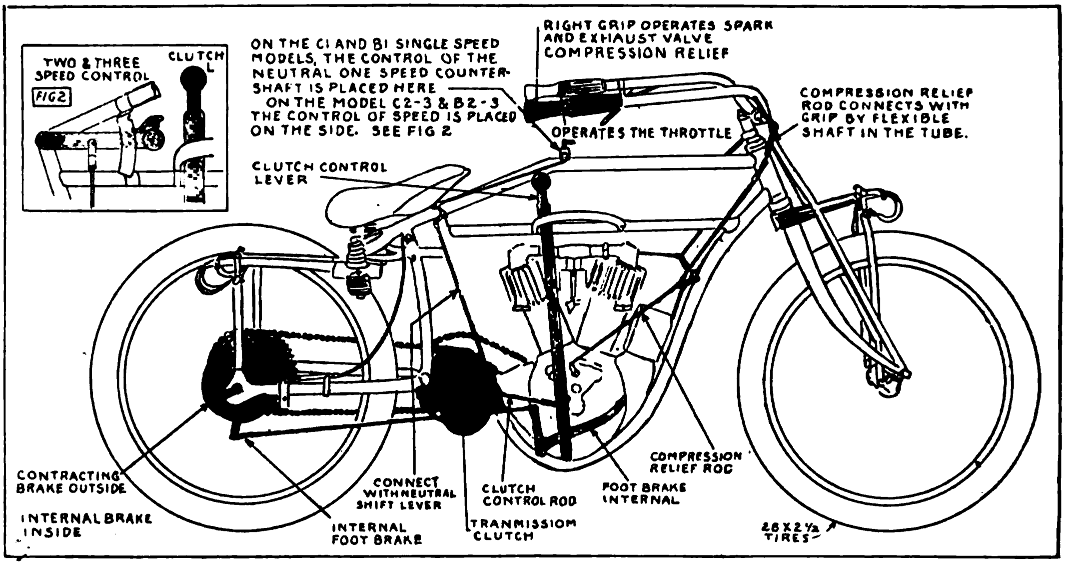

Fig. 1—The Indian Twin type of motorcycle using a neutral counter shaft as described on page 845.

If machine is equipped with this one speed device, called a "neutral counter shaft," its purpose is mainly to promote starting without raising the rear wheel. By shifting the small lever underneath handle bar, the dogs are disengaged and drive to the rear is cut out. The clutch is then engaged and engine started. After engine is started clutch is disengaged until machine is started.

If the three speed gear box is used instead of a single speed—it is mounted in the same location, but a control lever is placed on the side as shown in fig. 2, instead of the small hand lever. When starting with a two or three speed, the gears are shifted to neutral position and the action is just the same as above. Note the name and location of parts as lettered.

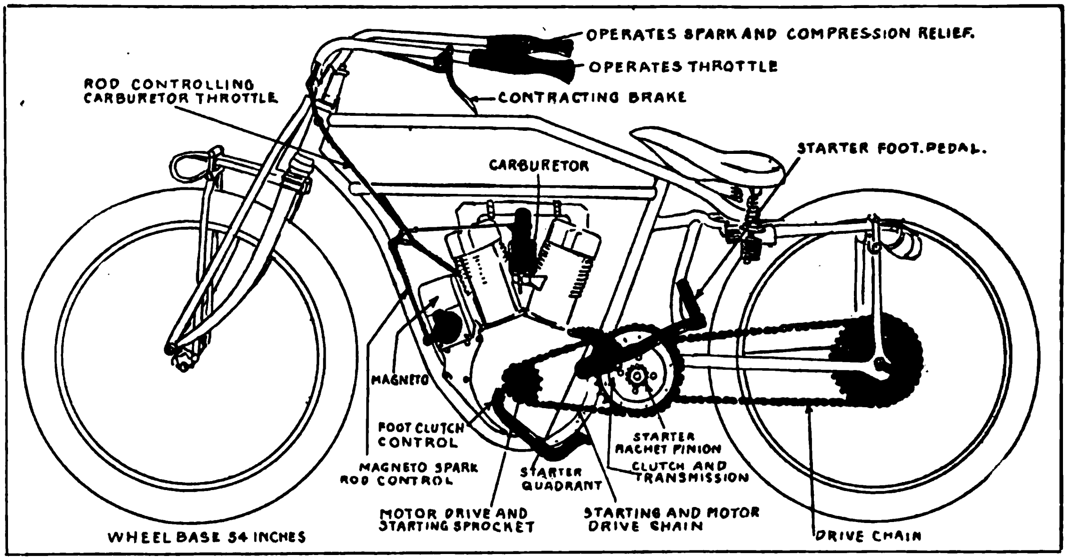

Fig. 2—The Indian starter: The down pressure on the foot lever brings the quadrant into engagement with the pinion on the clutch and turns the engine over three times to each stroke, the clutch being engaged to obtain positive and full crank effect.

This starting of the engine can be done without jacking up the rear wheel, simply by putting the shifting lever into neutral on the three-speed machine and by disengaging the driving cog in the same manner on the single speed model.

When the starting crank is released on the bottom of the stroke it is automatically returned to the starting position by a strong coil spring and when not in use is held in a convenient position by a strong clip. When the starting crank is in normal position it is fully disengaged from the pinion which revolves with the clutch.

The mechanism consists of a quadrant with a reverse motion and meshes with a ratchet pinion on the clutch shaft. The ratio is three turns of the engine to one stroke of the starter, not taking into account the spinning effect and extra momentum gained.

See Chart 385 for description of the Indian three speed gear and index for Indian engine.

CHART NO. 384—The Indian Control and Method of Starting.

Ignition on Indian is Dixie high tension magneto. See insert No. 8 and page 811 for "Mag-Dynamo."

Note: The above models are the 1914 and 1915 models. Changes have been made on the 1919 and 1920 models. The "Neutral Countershaft" has not been used on the Indian since 1917 and wire controls have been used since 1918. The gear shift lever and clutch pedal arrangement has also been changed.

Motorcycle Clutch and Transmission—Indian Three-Speed as Example.

Operating plan of three-speed Indian motorcycle: The principle of construction and operation of the three-speed gear are identical with the two-speed, except that there is an extra set of gears for intermediate ratio.

When gears "A" and "B" are locked together by dogs "G," the "high ratio" or "high speed" is coupled up.

When gears "B" and "E" are in mesh, "intermediate" or "second speed" ratio is obtained.

And when gears "B" and "C" are connected through the dogs "H," the "low speed" is obtained.

There are two "neutral" positions in this gear set; between the high and intermediate with the gears as shown in the illustration, and between the intermediate and low, with gear "B" on the other side with "E," with the same relative position.

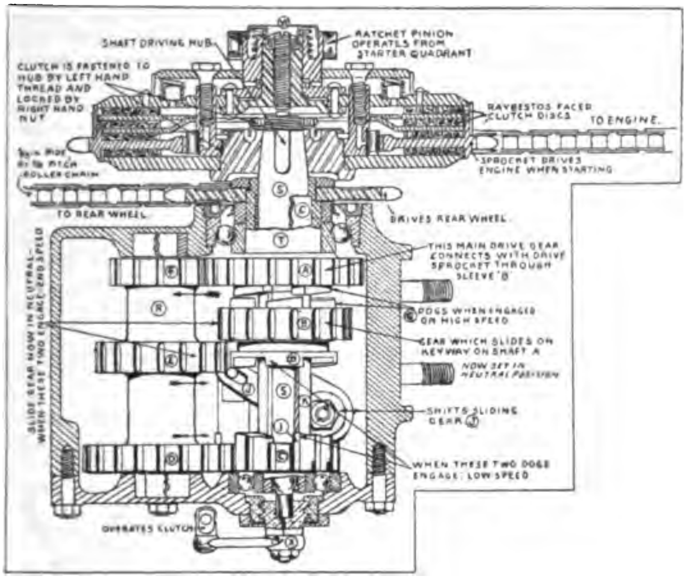

Fig. 2. The Indian clutch and 3-speed transmission.

Indian Clutch.

Construction: The Indian clutch is a multiple disc dry plate type. The drive is transmitted through four Raybestos faced discs which engage with four polished steel discs and are held on engagement by eight small springs equal distances apart.

This clutch is applied to the one, two or three speed transmission.

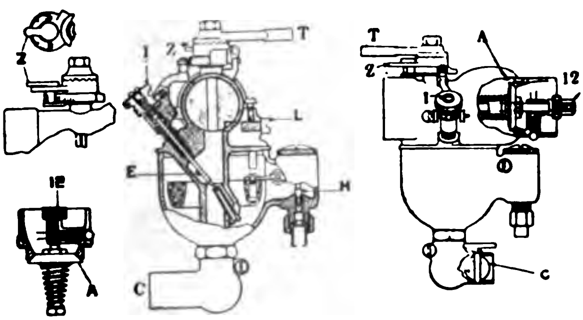
Operation: Lever "X" operates clutch and has about 45° travel. When pulled forward it releases clutch; backward it engages clutch.

It is connected with foot pedal, which has a pull back spring. Pressure on pedal forward, causes the plunger rod (marked by mistake, "shaft driving hub") to come in contact with the screw "W," which under pressure compresses the springs and pulls the whole assembly mounted on the inner plate—outward—thus freeing the driving discs.

When control pedal is released, the pull back spring causes a reverse action through the mechanism and again brings the discs into engagement.

Schebler Motorcycle Carburetor—Used on Indian and Harley Davidson.

Description; model "H," ¾ and 1 in. Compensating type. Variable fuel feed. Supply of gasoline controlled by (Z), which raises the gasoline needle valve (I), which gives an adjustment on low, intermediate and high speeds. C—is air intake and can be turned so warm air can be drawn from engine.



Low speed adjustment: See that the leather air valve "A" seats lightly, but firmly. Then turn knurled button "I" to the right until the needle point "E" sets in spraying nozzle. Now turn "I" to left about two turns and open low speed adjusting screw "L" about three turns, then open throttle about half way to start engine. After starting close the throttle and turn needle valve adjusting screw "I" to the right or left until engine runs smoothly without missing. If with this low speed adjustment, engine runs too fast, turn low speed adjusting screw "L" to the right.

High speed adjustment: Do not make the adjustment with the engine running idle. The machine should be run in high speed on the road. The throttle and spark should be advanced fully. The adjustment is now made by the pointer "Z," which as it moves from "1" toward "8" increases the supply of gasoline. Moving the indicator from "8" toward "1," cuts down the flow of gasoline. When the indicator reaches the right point, the engine will run without missing or backfiring.

Starting—air valve can be locked to assist in starting by pulling out button (12) and giving ¼ turn. When engine starts, release air valve (A) by turning button (12) back.

Extra air port for high speed on the Harley Davidson carburetor is provided inside of mixing chamber to admit more air at extreme high speed.

To set float level—place float 19/32" from top of bowl to top of cork float. The arm can be raised or lowered to meet these conditions.

CHART NO. 385—Motorcycle Transmission; Indian Three-Speed as an Example. Schebler Motorcycle Carburetor.

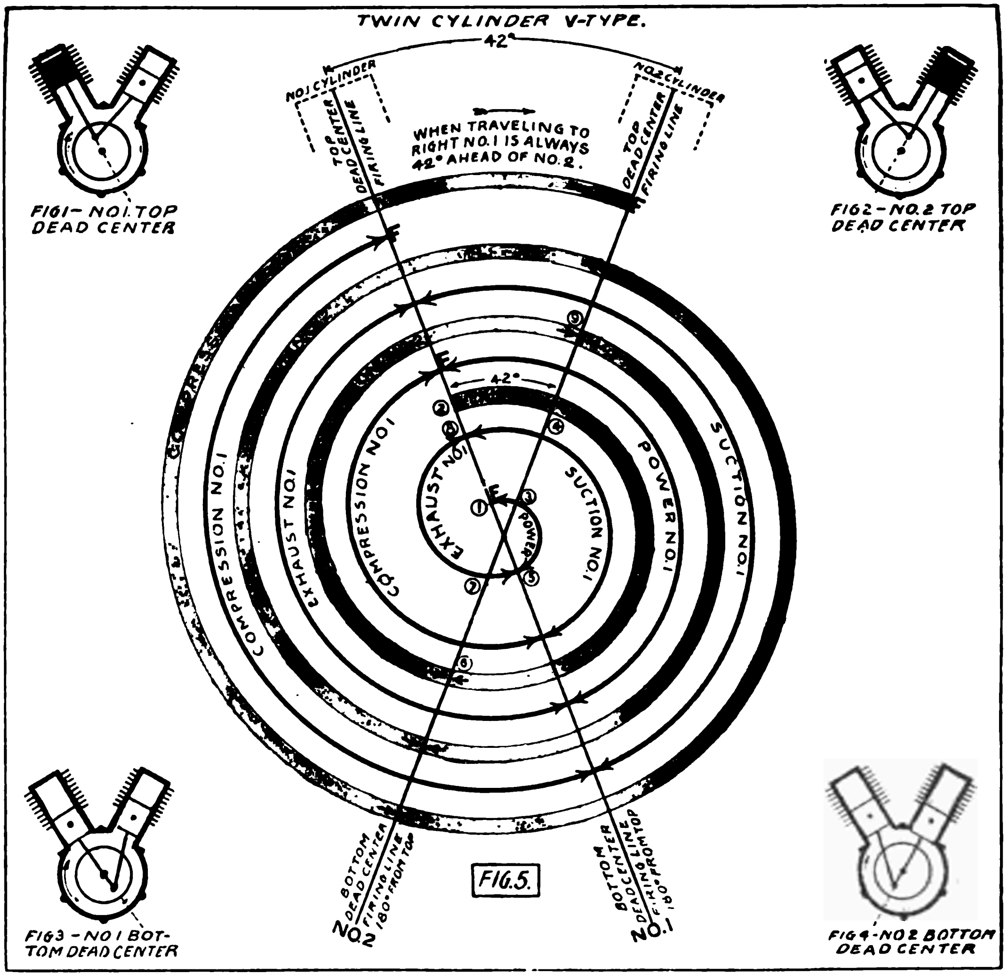


Fig. 1 illustrates two cylinders placed 42° apart. We will call cylinder to the left No. 1 and cylinder to the right No. 2. Bottom of connecting rods are together on one crank pin.

Note No. 1 piston is on top of its stroke and connecting rod is straight up and down, in line with the crank pin; in other words on its "firing center." (If it is on top of compression stroke, which we assume it is.) Piston No. 2, is not on top of its stroke; its connecting rod where attached to crank pin is 42° away from its firing center. No. 2 has 42° yet to travel to complete its exhaust stroke (see 2 to 4, fig. 5).

Fig. 2; No. 1 has fired and traveled 42° on its power stroke (see 1 to 3, fig. 5). No. 2 piston is now on top of its suction stroke (4) and on its dead center firing line.

Fig. 3; No. 1 has reached bottom of its firing or power stroke (see 5, fig. 5), having traveled 180° or half a revolution. No. 2 is not quite down in its suction stroke, being 42° behind No. 1.

Fig. 4; No. 2 has now reached bottom of stroke on suction, having traveled 180°, whereas No. 1 is part the way up on its exhaust stroke.

Therefore, starting with firing of No. 1 at 1F; if No. 1 makes a complete revolution; one stroke down on power stroke and one stroke up on exhaust, from 1 to 8—it will have traveled 360°. No. 2, however, will lack 42° of completing its revolution, and will have to travel 42° more than 360° to complete its revolution from 2 to 9.

Therefore when No. 1 travels 360°, No. 2 must travel 360 + 42 or 402° before it fires. Or No. 1 will fire again, 318° after No. 2 fires.

Fig. 5; black line shows travel of No. 1 and shaded line of No. 2. The firing lines of each, or top and bottom center are lettered on illustration.

Start with No. 1 firing at (F) and follow the stroke to bottom or a half revolution; for instance, from 1 to 5 on No. 1, and 4 to 6 on No. 2; each represent a stroke or half revolution or 180°.

From 1 to 8 on No. 1, represents a revolution or 360°.

From 2 to 9 represents 42° more than a revolution on No. 2. From 4 to 9 would represent a revolution on No. 2.

While observing the travel of No. 1, at the same time follow No. 2 and note what it is doing. For instance, when No. 1 is traveling from 1 to 3 on its firing or power stroke; No. 2 is traveling from 2 to 4. on its exhaust stroke, having 42° of its exhaust stroke to complete before it is on its dead center, when it starts on its suction stroke.

CHART NO. 386—Firing Order of a "V" Type Twin Cylinder Engine; cylinders 42° apart and both connecting rods on one crank pin. (See Chart 45, page 93 and study meaning of degrees.)

See insert No. 8 for Dixie motorcycle magneto and page 811.

How To Repair Tops.

Any repair shop, by the investment of a small amount of money in equipment, and the exertion of reasonable care, can develop a profitable top repair department. It is as an essential part of the trade as is the machine shop or the vulcanizing shop.

Only a small amount of equipment is necessary in a top repairshop, and this, with the exception of the sewing machines, may be made by the repairman himself.

The top building frame is shown in fig. 2, and it is only used when the car for which the top is being repaired cannot be left during the work. It is simply an adjustable framework upon which the top may be placed in exactly the position it occupies when up, and on the car. For each car the frame is set to duplicate the measurements of the top supporting irons and the car body. Then the workman can repair or rebuild the top with assurance that it will fit when returned to the car. **When possible, the top should be left on the car during the repair.**

In order to render all parts of the top accessible, when left on the car, a framework shown in fig. 3 is set up around three sides of the car. This framework is about 18 in. high, and comprises three planks resting on four small wooden horses. **Another method of accomplishing the same result,** yet one which the author has never seen, would be to construct a pit below the floor level. This would permit the workman to work directly from the floor and save the time lost in stepping to and from the platform.

All work is laid out and cut on the laying out table shown in fig. 4. This table is about 6 ft. wide, 12 ft. long and 28 in. high. A notched rack at one end supports the rolls of top material and enables the workman to readily obtain or replace the top material when desired. Rolls may be easily removed from the frame, or as many as three rolls of material may be carried at one time.

The tools of the workman are few, comprising a light cross pene **hammer,** with a tack puller fitted to the end of the handle; a heavy pair of **shears,** a small **cold chisel** and a **nail** set or **punch.** These are carried

in a special apron, made of top material, as shown in fig. 5. In addition, a **carpenter's** square, a 10-ft. straight edge, a yard stick and a plumb bob are required. The plumb bob is used to plumb up the edges of the back curtain, when fitting, to make certain that they are hung straight.

In addition, several special punches and dies will be necessary for cutting the openings for the curtain fasteners. One of these—styled the **Murphy die**—is shown in fig. 7, and corresponding dies are used for each type of fastener.

The sewing machine used in this work is of extra heavy construction, and is similar to those used by harness makers. These machines should be motor-driven, and may be purchased from almost any reliable sewing machine manufacturer.

So much for the equipment—now for the method of doing the work. Briefly this consists of removing the top material, part by part, using the parts as patterns to cut the new parts by; fitting the parts to the top frame; removing the parts; sewing them together, and then placing them again on the frame. Careful work is essential, and after carefulness has become a habit speed may be developed. Carefulness, then speed, are the only two requirements for a successful top repairman.

The following is a typical example of the method used in re-covering an automobile top. Though it specifically applies to a Ford top, in general, it may be applied to any car.

1—**Remove the top covering from the frame,** part by part, using the hammer and cold chisel as tools. Note how each part is fastened, as the rebuilding must be exactly the reverse of the tearing down.

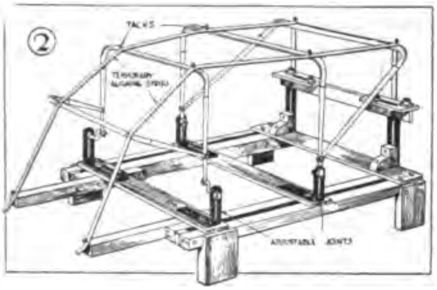
2—**Using each part as a pattern, one by one, mark out the new parts on the top material.** Care must be taken to allow extra material at the edges for fastening the material to the frame. The method of constructing the rear quarter is shown in fig. 10, and this method applies in general to each of the top parts.

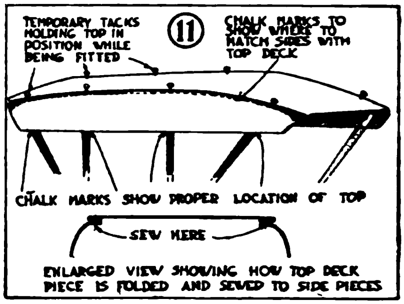
All metal fastener holes should be punched, using the holes in the old parts as guides, and all square corners should be checked up by means of the square. **The parts are then sent to the machine,** and the necessary sewing done. The **celluloid windows** are also placed in the rear curtain at this time.

In the meantime the top frame should be placed in good condition. If any bows are broken new bows should be fitted. Ordinarily new wrapping should be tacked around the bows, but if this wrapping is only faded, it may be dyed to conform to the inside of the top material.

3—**The side pad covers should now be made,** according to the pattern shown in fig. 8. On the Ford black cambric is used, but in every case the material should conform in color and quality to that used in the top material.

Dr. S. A. Peake's method of vulcanizing small holes, large as ½ inch in tops is as follows: First clean both sides of surface with gasoline, then use "Mastic" or "Tire-Doh" and work it to a point and insert in hole, filling hole. Cut off on each side. Then place a hot sad iron underneath and on top. This will vulcanize the Mastic in the hole.





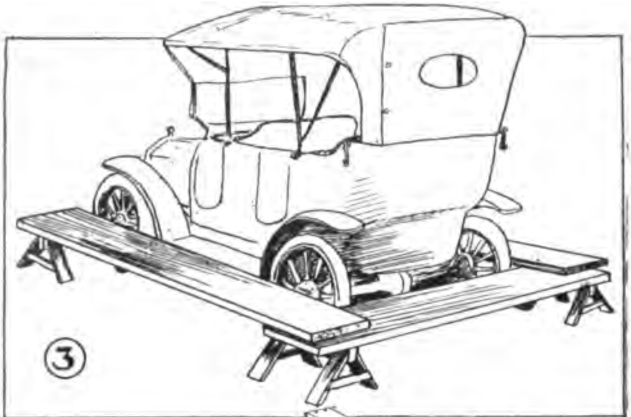


Fig. 2: When the car cannot be left in the shop, this adjustable frame enables the mechanic to duplicate the method of holding used on the car.

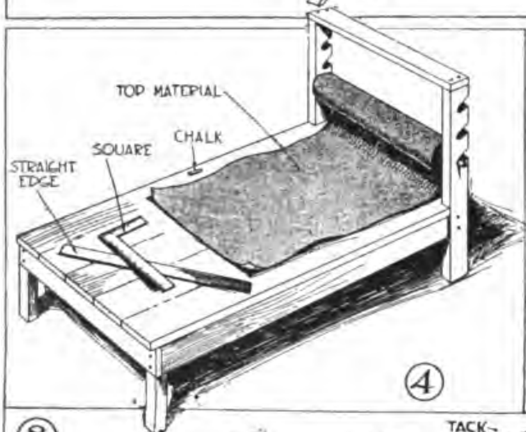
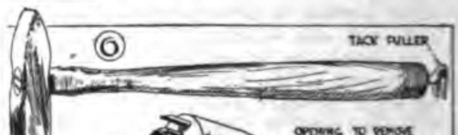
Fig. 3: Most tops are repaired right on the car, and a framework on three sides of the car renders all parts accessible.

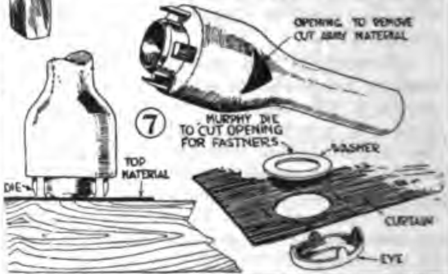
Fig. 4: The rolls of top material are carried on rods hung in a notched upright, and the material is marked out and cut to form on the laying out table.

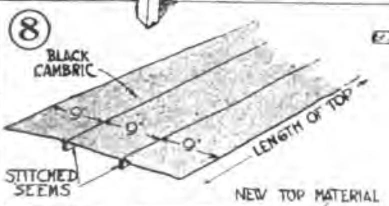
Fig. 6: The other end of the hammer handle is fitted with a tack puller, thus combining the two tools.

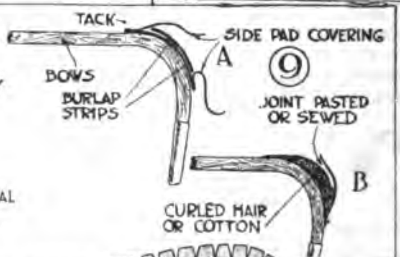
Fig. 7: Special dies are required to cut the openings for the fasteners. This is a most common type.











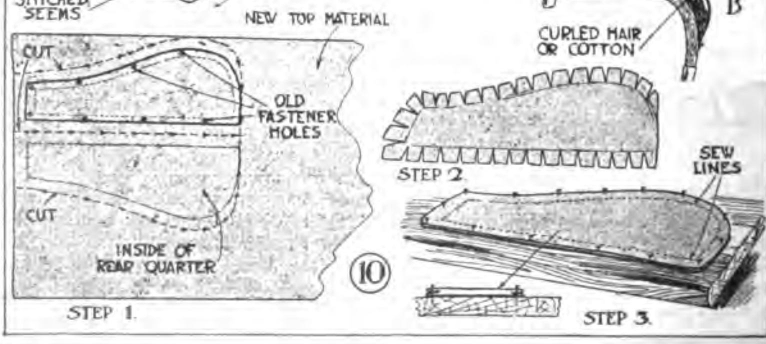


Fig. 8: The side pads are a single strip of cambric 29 in. wide, and sewed as shown.

Fig. 9: This is the method of building up the side pads.

Fig. 10: This shows the various steps in laying out and cutting a rear quarter. It is then taken to the machine and sewed.

Fig. 11: After all parts of the top are made, they are temporarily tacked to the bows and fitted. When a perfect fit is secured, the edges are marked, and the parts removed and sewed. They may then be replaced on the frame and permanently fastened in place.

CHART NO. 387—How to Repair a Top.

(From Motor World, by S. Thorton Williams.) Note—The shop layout and special tools, together with the procedure, were obtained from the Barton Auto Top Co., Detroit.

4—Line up the top bows. The method of doing this is shown in fig. 2. Heavy canvas straps are passed over each side of the bows, drawn tight, and tacked in place. The front bow should fit down over the windshield; the two middle bows should be vertical, and the position of the rear bow can be gauged by the length of the straps holding it down to the body back.

5—The side pad liners are next tacked in place, and the burlap strips tacked tightly in place. After this the curled hair, or cotton packing, is replaced, and the side pad flaps pasted into place. If desired, the edges of the pad may be sewed together. The above operations are shown in detail in fig. 9.

6—The rear quarters and back curtain are now fitted and tacked in place, after the metal fasteners have been applied, as shown in fig. 7. All vertical edges are plumbed up with a plumb bob, as any edge out of the vertical here is particularly noticeable.

7—The two side quarters are now temporarily tacked in place, beginning at the front and working to the back. These quarters should be drawn tight, without wrinkling. The edges of the deck are then turned under, and the deck is temporarily tacked in place.

8—By carefully fitting and changing, the top may be fitted to the bows in exactly the position it is to occupy. When everything appears to fit correctly the side curtains should be placed in position, and if necessary, the tacks should be removed and the top pieces shifted until the side curtains fit. (In most cases new side curtains do not have to be made; but if so, the new curtains should be fitted at this point.)

When everything is right the mating edges of the top pieces should be marked with chalk, and these marks crossmarked, as shown in fig. 11. Then by joining the corresponding marks together, the sewing machine operator can sew the parts together correctly. Chalk marks should also be placed at the points the edge of the top crosses the bows. This permits the top to be correctly replaced after a sewing.

10—The parts of the top are then removed, and the flaps on the edges that are to be sewed trimmed down to a width of about 2 in. The parts are then sent to the machine and sewed together.

11—To complete the work it is only necessary to replace the top covering and tack it securely in place. All extending edges are removed and the joints covered by a narrow strip of cloth material fastened by black upholstering tacks.

The above covers the method of completely replacing the top covering, with the exception of the side curtains. As stated, this is rarely necessary, as the side curtains are little used. If desired, any one part of the top may be replaced with new material, providing the other parts are in good condition. However, if either the deck or side quarters must be replaced, it is necessary to tear the top completely down in order to sew it together again.

In cases where it is necessary to replace some parts of the top covering, it will usually be found advisable to renovate the interior and exterior of the balance of the covering to make it conform to the appearance of the new part. Or this renovating may be done at any time to improve the appearance of the top.

After applying any patches that are necessary; replacing broken windows, and tacking on new binding at the edges where required, the top should be thoroughly brushed and cleaned. Gasoline should never be used for this purpose if rubber is used in the top material construction, as its action is to destroy the rubber. Soap, warm water and a brush are all that are usually required.

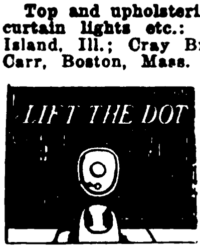
When the top is thoroughly cleaned and dried top dressing may be applied to outer surfaces, and the faded inner surfaces may be dyed black. There are many brands of top dressing on the market for this purpose, and any well-known brand should prove entirely satisfactory. By exercising a little care, the appearance of a shabby top may be greatly improved by this simple cleaning, patching up loose ends and application of top dressing.

Where to Obtain Top Material.

Tools; such as eyelet punches and dies for sockets and eyelets, special hand screw drivers, curtain fasteners, etc.: Carr Fastener Co., Cambridge, Mass. G. W. Murphy Co., Amesbury, Mass.

Top material; Cray Bros., Cleveland, O.; Du Pont Fabrikoid Co., Wilmington, Del.; F. S. Carr, Boston, Mass.; L. C. Chase Co., Boston & Chicago; Pantasote Co., 11 Broadway, New York.

Top and upholstering dressing and celluloid for curtain lights etc.: Arsenal Varnish Co., Rock Island, Ill.; Cray Bros., Cleveland, Ohio; F. S. Carr, Boston, Mass.



Lift the dot fastener is a very popular curtain fastener. To unlock and remove, lift dotted end of socket which is placed nearest edge of curtain. It is natural to lift the edge of the curtain so there should be no difficulty in remembering to always "lift-the-dot" and avoid tearing the curtains. Mnfgd. by Carr Fastener Co., 31 Ames St., Cambridge, Mass.

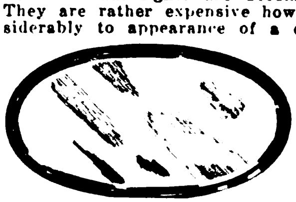
Rain shields similar to illustration fig. 6, page 732, for placing over the wind shield to prevent snow and rain accumulating is another profitable accessory to handle—mnfgd. by Jos. N. Smith Co., Detroit, Mich.

Seat covers are profitable to handle. Cray Bros., Cleveland, O.; Glover Eq. Co., Indianapolis, Ind.

Top and upholstering dyes and dressing—Cray Bros., Cleveland, O.

Complete Tops—Cray Bros., Cleveland, O.

Glass curtain lights are becoming very popular. They are rather expensive however but add considerably to appearance of a car. **The glass is beveled and comes with frame ready to place in curtain. The Borbein Auto Co., 2109 No. 9th St., St. Louis, Mo. will supply this—also top material, etc. in small quantities.**



Supplement
ON THE
PACKARD
TWIN SIX-"3-25" and "3-35"

Packard Operation.

Preliminary to starting; put gear shift lever in neutral (see page 498 for location of parts). Set hand brake. Set spark lever in mid position (see page 858). Be sure air gauge shows pressure in tank—if not, use hand air pump on instrument board (page 498). Open throttle about one-sixth.

Adjust air valve control, which is to the right of gasoline gauge (see page 855). **Cold weather** pull all way out to "choke." **Warm weather** this will not be necessary.

To start engine: turn ignition switch to "ignition." Crank engine, using electric starter.

After engine starts; push air valve adjustment in and set at best running position. Close throttle until engine runs slowly—a finer adjustment can be obtained by setting the mixture control with the throttle closed.

To start car; usual procedure. See pages 486, 488. The movement of gear shift lever is shown on page 498.

Standard Adjustments.

Ignition interrupter points should be set .015 to .020 inch when fully separated.

Ignition timing: The spark setting in the fully advanced position should be 2⅝ inch (measured on the circumference of the fly wheel) before upper dead center.

Should it become necessary to check this, proceed as follows: Remove motor starter switch cover over fly-wheel. Set the spark lever on the steering wheel in the fully advanced position. Open all priming cups with the exception of the one in No. 1 cylinder in the right block. Crank the engine by hand until compression begins in this cylinder, then open this priming cup and continue to crank the engine slowly to the point where the right interrupter points just begins to separate. In this position, the letters "S. R." on the fly-wheel should be just opposite the center line of the engine, as indicated on the crank case.

In order to test the synchronism of the left hand block, proceed as above excepting that the priming cup in No. 1 cylinder in the left block should be closed. Under these conditions, the letters "S. L." should be just opposite the center line of the engine as above.

Spark plug points should be separated .032".

The auxiliary air valve should have 5⁄32 inch drop when the control on the instrument board is set for the best idling position. To check, proceed as follows:

Set the auxiliary air valve control for the best idling position. In this position groove No. 4 is flush with the end of instrument board bracket.

Measure height of top of air valve stem from some fixed point on the engine. Depress air valve until it strikes inside spring. Measure height of top of stem as before. The difference in these two measurements is the air valve drop.

Make sure that air adjusting connecting rod clevis is so adjusted that the air shutter completely closes when the control on the instrument board is pulled out. See also page 854.

Clutch brake: Adjustments for wear can be made by loosening the nut on the stud which projects through the slot in the clutch cover and by sliding the whole assembly toward the rear.

Before tightening the nut, be sure that the brake facing does not make contact with the clutch brake disc when the clutch is engaged.

The amount of clearance should be governed by the speed of shift desired.

The standard setting allows ⅛ inch to 5⁄32 inch compression of spring with the clutch completely disengaged.

To adjust the foot (external) brakes properly, make the clearance between the band and the drum 1⁄32 inch and equal all around. In making this adjustment proceed as follows:

Adjust the nut on the rear support until the clearance between the drum and the brake band is 1⁄32 inch at this point.

Adjust the two nuts on the shank of the clevis just below the eye bolt at the front of the brake until the distance between the lower half of the brake band and the drum is 1⁄32 inch.

Adjust the T handle, which operates the adjusting screw, until there is a clearance of 1⁄32 inch between the upper half of brake band and drum.

The hand (internal) brakes should be evenly adjusted so that when applied there is the same resistance on each rear wheel. The following adjustments are to be made:

Make all adjustments for wear on the side pull rods connected to the cam shaft levers.

By removing the rear wheel the hand brake band can be set concentric with the brake drum by means of the adjusting set screw at the rear. The band should just clear the drum at this point.

Hand lever should be in the sixth notch from the front when brakes are applied.

Adjust accelerator pedal to have a clearance of 5⁄16 inch between pedal and top of floor board when throttle is wide open.

The oil pressure should be 20 to 25 pounds at 1000 revolutions per minute; corresponding to a speed of approximately twenty-five miles per hour; with the engine hot. A lower pressure when the supply is up to level indicates that the oil being used has low viscosity or that the relief valve opens too far.

To adjust the relief valve opening, change tension of relief valve spring located in pump housing—see page 859.

Compression in the cylinders should show 75 pounds plus or minus 8 pounds pressure with engine cold and at cranking speed, with all cylinder petcocks closed and the throttle wide open.—(see also page 853.)

Gasoline pressure: gauge on instrument board should show 1½ to 2½ pounds pressure.

The pressure may be increased by removing the plug at the top of the pressure pump cylinder and unscrewing the smaller plug at its base. To decrease pressure, screw in the plug.

Valve clearance: Inlet and exhaust valves should have .004-inch clearance between valve stem and roller holder set screw when engine is cold. Be sure that valve is fully seated when measuring clearance.

The vibration damper on the front end of the crank-shaft should be adjusted to slip under a pull of approximately 140 lbs.

Clutch pedal: When the clutch is in the fully engaged position, the pedal should depress 1¼ inch under light spring pressure before resistance of the heavy clutch spring is encountered.

If the pedal is brought against the floor board before the clutch is entirely engaged, full action of the clutch spring is not obtained which will cause the clutch to slip.

The rod connecting the clutch pedal with the clutch release lever on the left of the clutch housing gives the necessary means for obtaining the correct adjustment for the clutch pedal. Lengthening the rod by means of the thumb screw will increase the amount of travel under light pressure before disengaging clutch.

No other change from the original adjustment will be required as clutch surfaces are automatic in their compensation for wear.

Front wheels should "toe-in" ⅜".

Engine Features.

The twin-six engine is of the four-cycle type with two blocks of L head cylinders bolted to the crank case at an inclined angle of sixty degrees. The cylinder bore is 3 inches and the stroke 5 inches. The left block is set 1¼-inch ahead of the right block to permit the lower end connecting rod bearings from opposite cylinders being placed side by side on the same crank pin. This arrangement also permits the use of a single cam shaft with a separate cam for each valve operating directly on the valve push rod roller.

Compression in all cylinders should be equal and up to the standard. Weakness or loss of compression is most probably due to imperfectly seated valves, which may be caused by insufficient clearance between the valve stems and lift rods, carbon deposits on the valve seats, or by sticky valve stems and guides. Compression should be tested for uniformity in all cylinders at regular intervals.

To test the compression in a cylinder, remove the spark plug and replace it with a standard compression gauge. Then with the ignition switch off and pet cocks in all cylinders closed, crank the motor, using the electric starter. At cranking speed with the engine cold, the gauge should register 75 pounds plus or minus 3 pounds with the throttle wide open.

A change in the setting of the cam shaft is possible only by removal or disarrangement of the front end chain. Adjustments to the chain do not affect the valve timing.

In resetting the cam shaft, the arrows on both the crank shaft and cam shaft gears should point directly upward and should be in line with the arrow on the front end cover face of the engine. In this position, the inscription on the fly-wheel, "Exhaust closes 1 and 6-R," will be on the top dead center line of the engine, which is the center between the two cylinder blocks, and No. 1 right piston will be in the firing position.

The main and connecting rod bearings are of the babbit-faced bronze type. The bearings are set with a .0015 to .002-inch clearance and are consequently flooded with a film of oil between the shaft and the bearing surface, making adjustment for wear necessary only at long intervals.

To grind the valves disconnect carburetor inlet manifold and spark plug connections and remove cylinder heads.

CHART NO. 391--Packard Engine, Front View.

Gasoline System.

General principle: The supply of gasoline is carried in the tank at the rear of the frame. The gasoline is supplied from the tank to the carburetor by air pressure provided by an air pump attached to the engine front end cover and driven by the forward extension of the generator shaft.

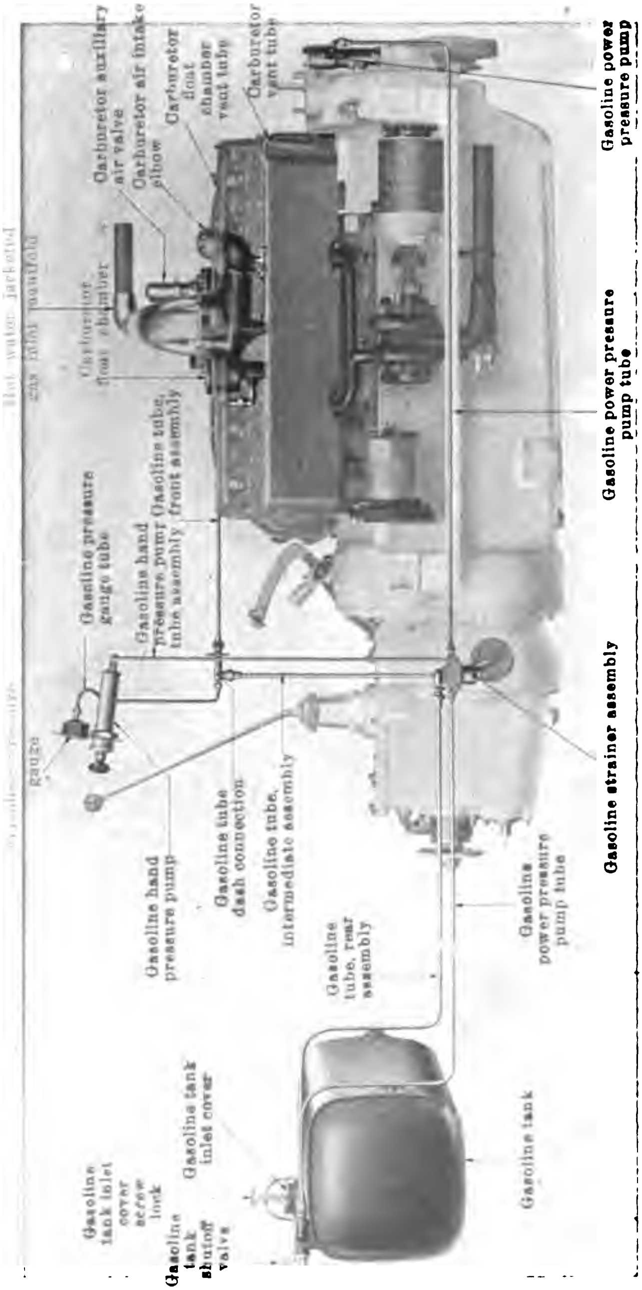
The carburetor is mounted above and between the cylinder blocks and receives the heat generated by the engine, which assists in the vaporization of the gasoline.

The gasoline tank is located on the rear of the frame. The capacity of the tank on all models is twenty gallons, including about a three-gallon reserve.

A three-way valve located on the top of the gasoline tank connects with outlet pipes leading to each side of the tank. Turning the valve handle to the right permits the gasoline to be completely drained from the right side of the tank and vice versa.

When gasoline has ceased to flow, turn valve handle to its opposite extreme regardless of the previous running position in order to obtain the reserve supply. Turning the handle straight up, shuts off the gasoline.

Caution: If gasoline tank has been completely drained and is replenished with less than five-gallon supply, turn the valve handle to the left, which is the side of the tank which receives the first three to five gallons. Otherwise, the gasoline will not flow.



Air pressure for supplying gasoline to the carburetor is furnished by an air pump attached to the crank case front end cover, and driven by an eccentric mounted on the generator shaft.

The air is drawn from outside the crank case and forced under pressure to the gasoline tank. To increase the pressure, remove the plug at the top of the pump cylinder and unscrew the smaller plug at its base. To decrease the pressure, the small plug should be screwed down.

The hand or auxiliary pump on the instrument board provides a means of obtaining initial air pressure before the engine is started, providing the gauge on the dash shows that there is no air pressure in the gasoline tank.

To obtain pressure by hand, unscrew the handle to the left. When plunger is free, operate pump until pressure shows on the gauge. Do not pump higher than 2½ pounds pressure.

If the gasoline gauge does not respond to the hand pressure pump, it is probably caused by the tank outlet valve being shut off.

Caution: When through operating pump, push plunger in and be sure to lock it in place by screwing plunger handle to the right.

The plunger leather of the pump should be oiled occasionally with neat's-foot oil. Mineral oils improve the operation of the pump only temporarily and tend to dry up the leather.

A gasoline pressure gauge on the instrument board is connected directly with the supply line at the gasoline strainer housing. The gauge indicator should show from 1½ to 2½ pounds pressure when the engine is running.

If the pressure gauge indicates that the pump is not maintaining the proper pressure in the tank, proceed as follows:

Inspect gasoline tank filler cap, seat and gasket to make sure that they are in good, clean condition and free from nicks.

Be sure that the filler cap is tightly seated. If the trouble is not found by the above method, examine all connections on the air pressure and gasoline supply lines to make sure that there are no leaks. A good method of locating leaks in the air line is to put pressure in the tank and go over the line carefully with soap suds.

If it is determined that all pipes and connections are absolutely air tight, raise the air pressure by adjusting the pump as described above.

CHART NO. 392—Diagram of Gasoline Pressure System.

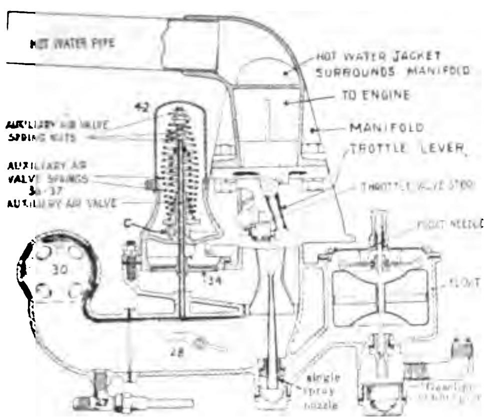


Fig. 1. The Packard Carburetor. The Fuelizer (fig. 2) is not attached.

Packard Carburetor.

The primary air intake elbow (30) is at the front end of the carburetor. The elbow contains a shutter (28) which is normally open and not in use when running. This shutter is operated by the "carburetor control" on the instrument board, which also operates the auxiliary air valve (34).

By pulling the control all the way out, the primary air intake is completely closed, allowing a very rich mixture to be drawn into the cylinders. The control should be pushed in, at least part way as soon as the engine has started firing.

The auxiliary air valve (34) is in a housing (42) forward of the mixing chamber and is controlled by the tension of two springs, one of which is within the other.

At low engine speed most of the air is admitted through the primary air intake (30) around the spray nozzle.

To prevent too rich a mixture at a greater throttle opening, the auxiliary air valve (34) is opened by the increase in vacuum, admitting the right proportion of air to meet all conditions.

Carburetor Adjustment.

There is only one carburetor adjustment which directly affects the mixture, and this is the auxiliary air valve adjustment. This adjustment is made by changing the tension of the air valve springs (36, 37). This is changed by either of two methods, the first being through the operation of cams (C) at the lower ends of the springs. Raising the cams increases the pressure of the springs, and lowering the cam decreases the pressure. Increasing the pressure produces a richer mixture and decreasing the pressure makes a leaner mixture.

These cams are controlled and operated by the air valve control on the instrument board.

The large outer spring is at all times under tension, but the smaller inside spring is not normally under pressure until the valve opens up a little.

The other adjustment of the springs is made by changing the position of the nuts on the stem of the valve. There are two sets of nuts, one for each spring, and they allow individual adjustment of the springs.

Under ordinary conditions, and with the engine warm, the control on the instrument board should be set at the No. 4 notch. Pulling the rod out makes a richer mixture and pushing it in makes a leaner mixture.

Caution: In warm weather, or if the engine is warm, the mixture may be so rich if the knob is pulled out that the charge will not ignite and the surplus of unburned gasoline may interfere with the proper lubrication of the cylinder walls.

For idling, the throttle valve is held very slightly open to allow a very small amount of mixture to go to the cylinders. If the engine races or stalls when the throttle is closed all the way, the stop screw needs adjusting.

The float chamber vent tube 27, also shown on page 854, is for two purposes: (1) to give air to float chamber to prevent a vacuum being formed; (2) to drain surplus gasoline from chamber around spray nozzle when engine is suddenly throttled down.

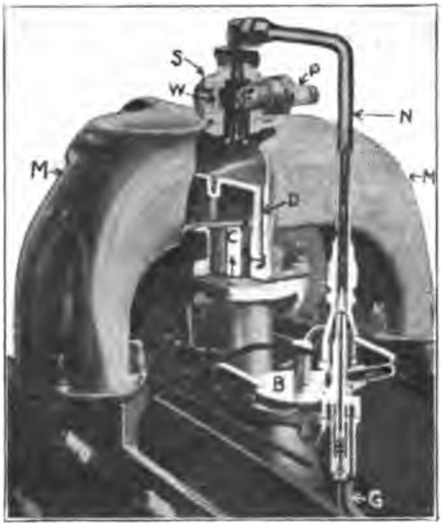

Fig. 2. The later Packard carburetor (B) is the same as in fig. 1, except the Fuelizer is attached to intake manifold and a gasoline connection (N) is provided for the Fuelizer.

The Latest Packard Carburetor is Equipped With a Fuelizer.

With the use of the present day gasoline, when first starting and until engine is thoroughly heated, raw gasoline passes into cylinders which not only produces carbon, but thins the lubricating oil on the cylinder walls and passes to crank case and dilutes the oil. The engine also frequently misses when cold.

To heat the mixture and provide complete combustion within 20 seconds after starting on the coldest day, the Packard Co. have developed a device to heat the mixture, called a Fuelizer.

The Fuelizer consists of a small supplementary carburetor and a burning chamber (S) where the gas from the little carburetor is burned. This chamber is situated in the intake manifold (M). When the gas enters, it is ignited by a regulation spark plug (P), and passes into the fresh charge going from the carburetor to the cylinders through wall D to C. The heat of the burnt gas changes the wet, poorly carbureted mixture to a dry vapor, which combusts with full efficiency when it is ignited by the spark in the cylinder.

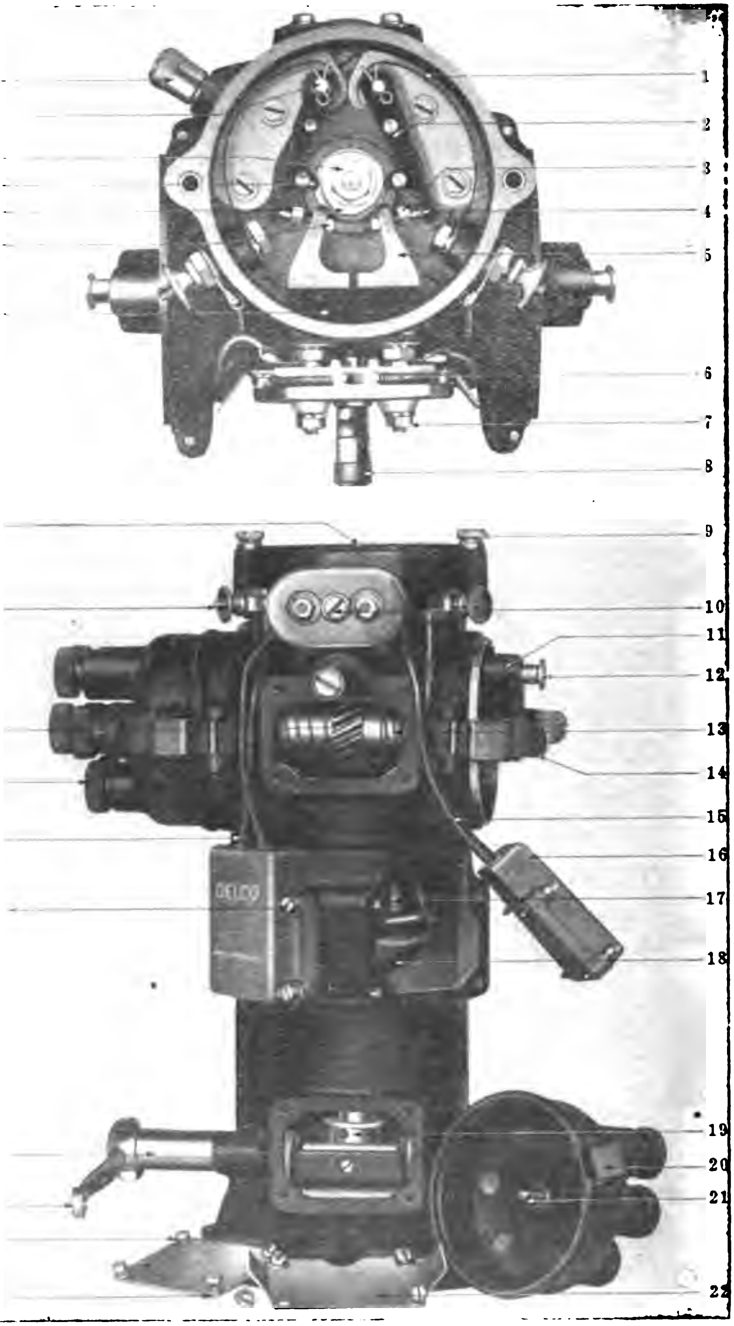
The action of the Fuelizer is entirely automatic, without involving a single moving part. When the engine is starting the Fuelizer is in full operation, and the heat supplied to the charge becomes less as the throttle is opened. This regulation is provided by an air-valve similar in operation to the air-valve of the main carburetor.

Through a small Pyrex glass window (W) the operation of the Fuelizer may be seen. A perfect mixture produces a purple flame, a fairly rich mixture produces a bluish-green flame, and an exceedingly rich mixture is indicated by yellow streaks in the flame.

B is the regular carburetor and G is the gasoline pipe connection to it from gasoline tank, which feeds the carburetor in the usual manner. **N** is a pipe which is connected with float chamber of carburetor from which gasoline is drawn for fuelizer by suction of piston.

CHART NO. 393—Packard Carburetor. Packard Fuelizer.

*See also page 850 "Auxiliary Air Valve."



Ignition Interrupters.

The twin interrupter or breaker, at the top of the distributor unit, completes the low tension circuit when the breaker points are in contact. When the points separate, the instantaneous clearing of the low tension current from the primary winding of the coil, induces a high tension current in the secondary winding, which surrounds the primary winding.

This high tension current is then conducted to the cylinder spark plugs through the distributor leads.

The breaker or interrupter mechanism consists of a separate set of breaker points for each low tension circuit. These are operated by a single three-lobed cam (36) mounted on the top of a vertical shaft which is driven at crank shaft speed. This causes each low tension circuit to be broken three times to each revolution of the crank shaft.

Arcing across the contact points when they are separating is minimised by the use of separate condensers (16 and 28) for each set of breaker points, located in the rear side of the ignition timer and distributer housing. Indirectly these condensers also serve to intensify the high tension current wave. Resistance units (6) in both low tension circuits, and located on either side of the common ground return terminal on the timer housing serves to keep the low tension current down to the proper rate of flow.

High Tension Distributors.

Separate high tension distributor heads are provided for each cylinder block. These are mounted on either side of the ignition apparatus housing and are operated by rotors on a cross shaft driven from the vertical timer shaft (see page 853).

Firing Order.

The firing order in each block is 1; 4; 2; 6; 3; 5; the impulses alternating between the two blocks. Numbering the cylinders in succession, beginning with number one at the front of the right block, the firing order would be 1R; 6L; 4R; 3L; 2R; 5L; 6R; 1L; 3R; 4L; 5R; 2L; the R and L designating the right and left cylinder blocks. (see page 135 for 1917 Packard firing order.)

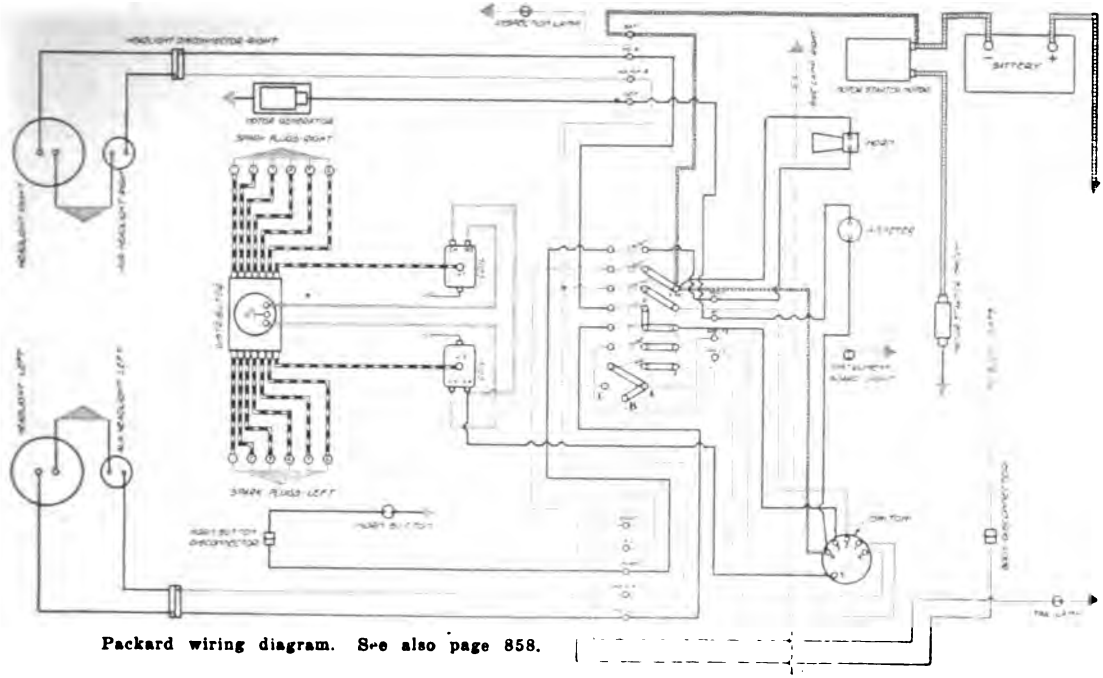
RT NO. 394—Packard Ignition Unit. Interrupter and Distributor. Packard-Delco System.
ages 377 and 378 for general principle of the Delco single timer. See also page 135 for 1917 Packard. on timing—see pages 850 and 135.

*Packard Electric System.



Packard wiring diagram. See also page 858.

Battery and Generator.

A 6 volt storage battery of 120 ampere hour capacity supplies current for lights and ignition when car is running at low speeds. The positive pole is grounded. Negative terminal connects with starter motor.

The generator charges the storage battery and supplies current for lights at higher speeds.

Generator regulator is located on top of generator. It is provided with three split pins which fit into the three terminal tubes on top of the generator body. This regulator box contains an automatic "cut-out" which opens the circuit between generator and battery at low speeds.

The generator regulator keeps a constant electrical pressure or voltage, slightly higher than the voltage maintained by a fully charged battery, this pressure being maintained regardless of speed.

The voltage being constant, the current generated naturally varies, being small when the battery is fully charged and increasing as the lights are turned on or the battery is partially discharged. The disconnect switch should be reversed every 1,000 miles in order to keep the points clean on the automatic switch.

The Bijur system is an electrical system with a polarity reversing switch. In this system, if we assume the generator to be at rest, then the reversal of the polarity reversing switch actually reverses the battery connections at the point where the generator charging lines leave the voltage regulator. When the generator starts to revolve it builds up a potential in the same direction that it had before reversal. At the instant the automatic switch closes, the battery voltage predominates and the momentary discharge reverses the shunt field and at the same time the battery current through the armature reverses it so that the polarity of the generator is reversed. As the connections between the battery and generator have been reversed through the polarity reversing switch, the generator charges the battery in the proper direction.

Electric Starter.

Starting motor is the Bijur automatic gear shift principle explained on page 328, and illustrated on **page 858.** Note fly wheel drive for starting. **Starter switch** is attached to top of crank case. Button protrudes through the board. It is operated by foot. One terminal is grounded. Other connects with battery, but by a terminal on starting motor.

Fuse Board.

All lamp circuits and horn circuit pass through the fuse board on the front side of dash. When lamps or horn fails, examine fuses. If fuse is o. k., then look for loose wires. **Fuses** are glass tube type. If fuses continually blow look for a short circuit causing it.

Ammeter.

The ammeter is located on the instrument board. It is connected between the generator and battery through the switch; thus, with the engine idle, the ammeter does not indicate, whether the lights are on or off. Should it register to the left of zero with the engine idle, remove the disconnect plug from the regulator, to prevent discharging the battery. When the engine is running the ammeter registers the amount of charging current passing from the generator to the storage battery and lights. If ammeter fails to register when engine is running about 750 revolutions or over 20 miles per hour, look for loose connections or broken wires between generator and battery, also see that generator commutator is clean and that brushes are making good contact. If ammeter shows a high current continuously of 25 or 30 amperes it indicates a heavy ground or short circuit in wiring or battery.

Disconnect the battery to prevent discharging and examine wiring for short circuits.

Electric Lighting.

All electric light appliances derive current through large cable leading from battery to starting motor, the other end of both lighting system and battery wires being grounded to complete the circuit.

Lamps—see page 434 for voltage and candle power of bulbs. The Ediswan base with single contact, page 438.

The tail and license lamp is so wired that it can either be turned on by a switch on the control board or by a revolving switch at the back of lamp.

In states (as Illinois) requiring the tail lamp to be turned on and off at the lamp, the connecting strap (A) on the fuse board should be connected to the terminal (C). In this case the circuit is controlled by the body light fuse, and the instrument board light by the tail lamp fuse.

Auxiliary headlights are smaller than the headlights. They are placed in front, to be used in place of headlights. The headlights are 24 c. p., 7 7 volt and the auxiliary headlights are 6 c. p., 7 volt. See diagram of wiring. They are sometimes called **dimmer lights.**

*For location of parts see illustrations on the different pages of Packard Supplement.

Ignition System.

Is the single wire or grounded return. The source of current is the generator with a storage battery in the same circuit. The battery circuit is completed through the metallic parts of the chassis. Ignition wires are shown in red. Light red lines are low tension and heavy red lines, high tension.

High and low tension wires are distinguishable by difference in size, the low tension wires have thinner insulation and low tension current is carried in a complete one-wire circuit grounded at the contact screw brackets. The high tension current is grounded from the spark plug body through the engine, the coil bracket and through the end studs on the inboard ends of the coils on the dash.

High tension wires from distributors to spark plugs are carried in tubes supported on the cylinder blocks. The wires between the coils and distributors are carried in the same tube.

Low tension circuit: The negative battery terminal is connected to the upper post on the front of the starter motor. From this live terminal, the low tension current is carried to the terminal marked "BAT" on the front face of the small wiring board. On the rear side of the dash it passes from this terminal to the post marked "6-BAT" on the large wiring board. From this terminal it passes to No. 6 on the switch and leaves at No. 5, running to both coils which it enters at posts marked "SW" and leaves at posts marked "DIS." Independent circuits from these coils carry the current to the terminals on the interrupter housing and through the breaker levers to breaker contact points for each cylinder block.

The high tension current which originates in the secondary windings of the transformer coils passes from the terminal H. T. on the front of the coils to the center terminal of the distributor board, thence through the distributor to the appropriate spark plug. The high tension current after arcing the spark plug gap, completes the circuit through the spark plug body, cylinder castings and crank case to the grounded studs on inboard end of the coil.

The switch on the instrument board has two positions. A low tension circuit is completed through either one set of breaker points or the other, whenever the switch handle is turned to "Ignition," and the battery current flows continuously. The car should, therefore, never be left unattended with the switch in this position.

Spark advance is automatic similar to other Delco automatic systems.

For starting and ordinary running, the hand advance lever which shifts the entire range of action of the automatic spark advance, may be set and carried in the midway position. For extremely low speed it is advisable to carry this lever in the fully retarded position and for extremely high speed in the fully advanced position. For maximum economy above fifteen miles per hour the lever may be fully advanced.

Replacing ignition apparatus if removed: It is assumed that the spiral gear (23, page 853) has not been moved.

Place the fly-wheel in the position explained on page 850. Remove the right distributor head from the ignition apparatus and rotate the distributor arm until its position corresponds with the position of No. 1 terminal on the distributor head. The ignition timer may now be set in place.

Keep the lever, which is near the bottom left of the ignition apparatus, in its downward position. The ignition unit may now be set in place and all connections made.

Any necessary adjustments for connections can be made on the adjustable clevis at one end of both the horizontal and vertical spark control rods.

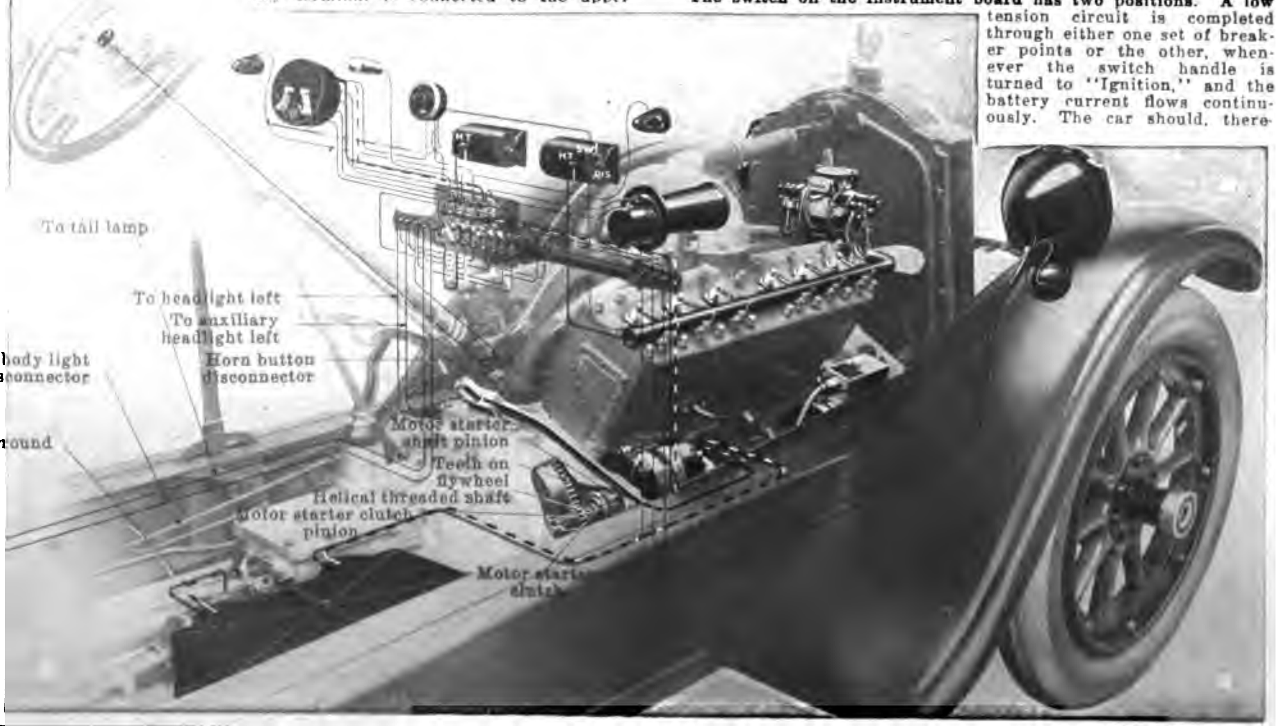


CHART NO. 395—Wiring View of Packard Electric System. Delco Ignition. Bijur Electric system otherwise. Black wires above are starting and lighting wires. Light red, low tension ignition and heavy red, high tension ignition.

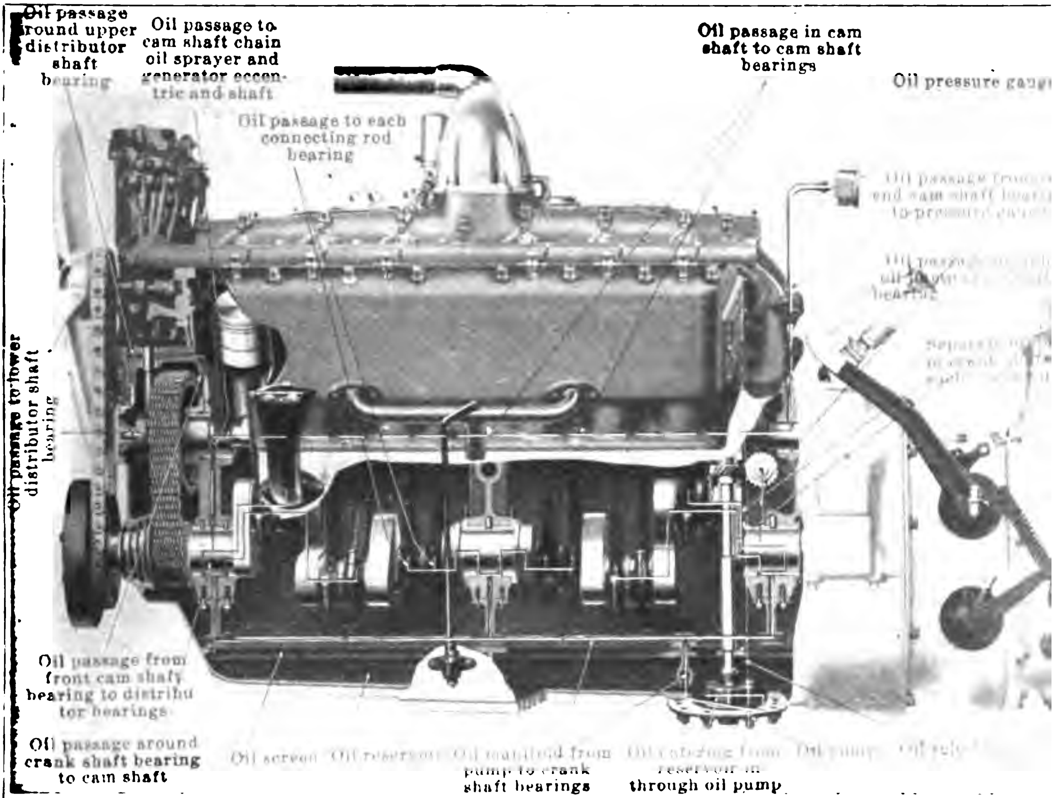

Principle of lubrication is force feed and is similar to the system described on page 198 (King).

Oil pump (see illustration below) is of the gear type. It is located at the lowest point of the oil pan and forces oil through a feed pipe to main oil distributor manifold, which is attached to the crank shaft bearing caps. See illustration above.

The pump is driven by a spiral gear on the cam shaft. It can be removed for inspection by removing nuts holding it.

The oil relief valve is contained in the pump body. It is controlled by the tension of a coiled sprin which should be set to maintain a pressure of fron 20 to 25 pounds with the engine warm and runnin at a speed of about 1,000 r. p. m., which is equiva lent to a car speed of approximately twenty-fiv miles per hour, and with a minimum pressure of pounds at 300 r. p. m. The inlet to the relief valv is connected with the pump discharge passage, an any excess pressure causes the valve to open and al lows the oil to return to the inlet side of the pum

To raise the oil pressure, remove the plug fron the bottom of the pump housing; loosen the jam nut on the adjusting stud and increase the sprin tension, by turnin the adjusting screv clockwise with screw driver, unti the proper pressur is obtained.

To lower the pres sure, the spring ten sion should be de creased. Be sure jam nut is screwed u tight before plug i replaced.

If the oil pressur drops below norm when the crank cas oil supply is up t the proper level, th cylindrical straine should be remove from the crank ca and cleaned. It shoul also be cleaned whe ever the supply oil in the crank ca is changed. This ca be done by removin the small plate fro the right hand si of the crank ca lower half, beari the inscription, "r move and disconne oil manifold befo taking off lower ha of crank case."

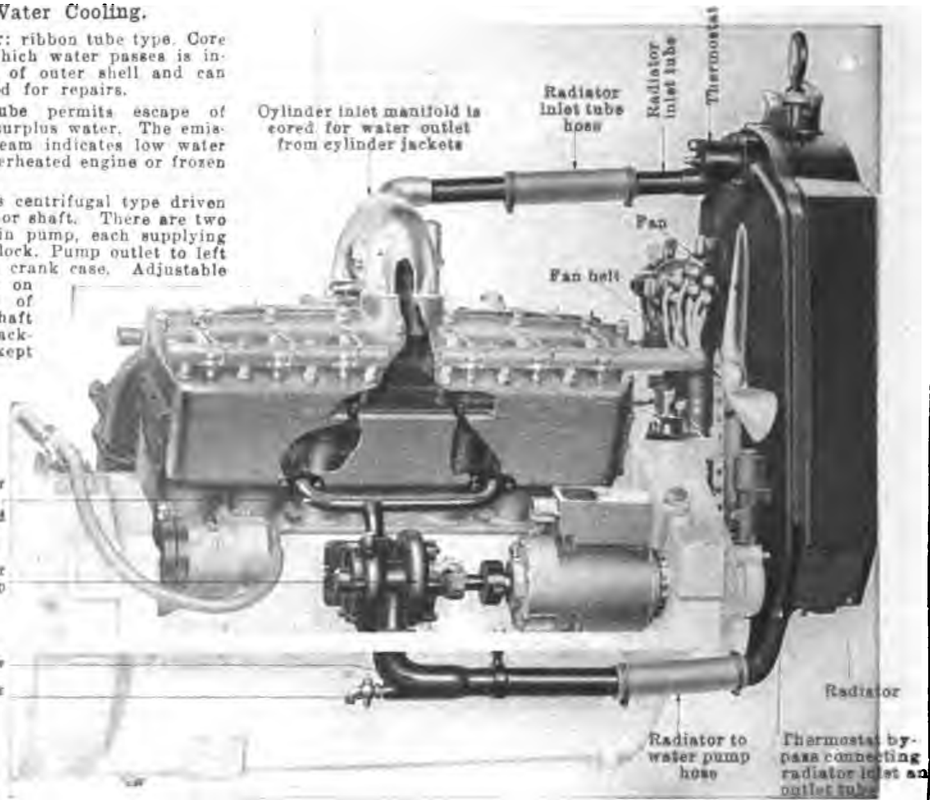
CHART NO. 396—Packard Engine Lubrication System. Oil Pump and Relief Valve.

Water Cooling.

Radiator: ribbon tube type. Core through which water passes is independent of outer shell and can be removed for repairs.

Vent tube permits escape of **steam** or surplus water. The emission of steam indicates low water supply, overheated engine or frozen radiator.

Pump is centrifugal type driven by generator shaft. There are two impellers in pump, each supplying a single block. Pump outlet to left is through crank case. Adjustable gland nut on front end of pump shaft permits packing to be kept tight.



How The Water Circulates.

The water is drawn from the bottom of the radiator by the **double impeller pump and is distributed through** the manifolds **to each of the cylinder block water jackets.** The outlet from **the cylinder water jackets is through the cored** water passage **surrounding the gas intake header, which connects** the cylinder **blocks and thence through the tube leading to** the top of the **radiator.**

The purpose of the water jacket surrounding the gas inlet **manifold is to furnish heat to assist in vaporizing** the gasoline.

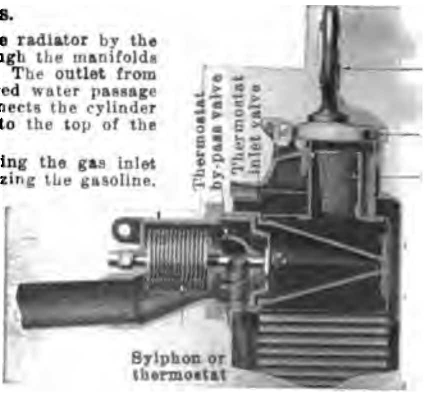


Fig. 2—A sectional view of the thermostatic water circulating system, showing the sylphon and inlet pipe to the left.

*Packard Water Thermostat

Located in the upper tank of the radiator, by-passes the water to the inlet side of the pump until it has reached the proper temperature to permit efficient running of the engine.

A by-pass tube connects the thermostat housing with the inlet side of the water pump. **Valves** controlling the entrance to the radiator and the by-pass tube are carried on a shaft actuated by the action of the thermostat sylphon.

Normally when the water is cold, the radiator valve is closed and the by-pass inlet valve is open, allowing the water to circulate through the cylinder jackets and back to the pump without entering the radiator.

As the water becomes heated, the expansion of the sylphon causes the radiator inlet valve to open, and at the same time closes the by-pass valve, making it necessary for all water to circulate through the radiator. No adjustment to the thermostat is necessary.

Clutch and Transmission.

Clutch: attached to the fly-wheel and enclosed in a housing bolted to the crank case casting is a multiple disc clutch. It consists of two series of dry plates which are alternately connected with a casing attached to the fly-wheel and with a spider on the clutch shaft. The casing or driving plates are faced with special friction material which contacts with the hardened and ground steel spider or driven plates.

The clutch plates are held in contact by the tension of a strong coil spring. Pressure upon the left pedal compresses the spring and allows the plates to separate slightly by sliding endwise on their respective keys, which connect the driving plates to the drum and the driven plates to the spider.

Transmission is the usual sliding gear type, giving three forward and one reverse speed. See page 498 for gear shift movements.

CHART NO. 307—Packard Water Circulating System.

*See page 130 for Cadillac water thermostat and pages 187 and 191. See page 730 for Cadillac condensing system.

INSTRUCTION No. 50.

DICTIONARY—Meaning of Motoring Terms.

Note:—If the Dictionary does not give the meaning, or if a description is desired,—see index for the subject.

A

Accumulators—A set of secondary cells—also called storage batteries,—containing positive and negative plates, and filled with electrolyte.

"Actual" horsepower is the amount of power that would be available if there was none absorbed by friction within the engine itself, and the total energy of the explosion was transmitted without friction or other losses to the engine shaft.

"Advanced" spark lever—see page 61.

A. L. A. M.—Means Associated Licensed Automobile Manufacturers. Now known as S. A. E. (Society of Automotive Engineers).

Alternating current—A current changing its direction of flow, or "alternating" backwards and forwards. See pages 439 and 266.

Aluminum—This metal, the chief characteristic of which is its lightness, is not generally used in its pure state, but is alloyed with a small proportion of zinc; sometimes, for special requirements, a small quantity of copper and manganese are added.

Ampere—The practical unit denoting the quantity of electricity. See page 207.

Ammeter—An instrument that indicates amperes or rate of current flow.

Ampere-hour capacity of a battery—is a term used to express the amount of current that can be gotten out of a battery of a given size. An actual 50 ampere-hour accumulator should be capable of giving 1 ampere for 50 hours, 2 amperes for 25 hours; but the ratio becomes disproportionate as a higher rate of current is taken from the cell.

Annealing—Softening of iron. By placing it in a fire and getting it red hot and then permitting it to cool without water it softens.

Annular ball bearing—see page 588.

Asbestos—This material is of mineral origin (large quantities come from Canada). In its natural state it is fibrous and somewhat brittle. As it resists great heat, it finds considerable application in motor work for engine jointing in the form of packing washers (of copper sheet and asbestos). Asbestos cord is used for covering exhaust pipes where these pass through woodwork, etc. Worked up into a fabric with brass wire, it is largely used for brake-band linings and clutch covering, as it cannot be burnt out by excessive friction.

Aviatrix—Feminine for Aviator. A woman who operates a flying machine.

B

Ballast resistor—see page 347.

Back-pressure—Term applied to restricted exhaust discharge. Unless muffler is of sufficient size there will be back pressure, and the exhaust will not be discharged as rapidly as it should.

Bezel—The groove in which the glass cover of speedometer or clock is fitted. (see page 512.)

Bore and stroke—see page 81.

B. H. P.—Brake horsepower—Measurement of horsepower of an engine of actual net work of the engine or horsepower delivered at the crank shaft. (see pages 535 and 537.)

British Thermal Unit, or B. T. U.—The amount of heat required to raise the temperature of 1 lb. of water 1 degree Fahr. (at its maximum density, which is at 39.1 degrees Fahr.) This expression is much referred to in the study of the value of various fuels for engines: thus gasoline ranges about 19,000 to 20,000 B. T. U. per lb. A pound of gasoline of 58 s. g. is approximately 8 tenths of a pint. 1 B. T. U. is equivalent to 778 foot lbs. of work—see also page 587.

C

Calorific value—This term is used with reference to various fuels, such as gasoline, benzol, paraffin, etc., and represents the effective heating power per lb. in terms of British Thermal Units. One lb. of gasoline contains about 19,000 b. t. u's.

Cam shaft—The shaft running through the engine which has the cams placed upon it at certain fixed positions.

Carbon—One of the well-known non-metallic elements. It is an excellent conductor of electricity. As applied to the automobile refers to the carbon deposit which accumulates in the combustion chamber of an engine (see page 623). In a hard state it works well as a contact medium in conjunction with copper or brass, it is, therefore, largely used for the brushes of the magneto, and also for the brushes of car-lighting dynamos. Carbon in its natural form of graphite is used as a lubricant for gearing. It is generally mixed with grease, and is supplied ready prepared by lubricant manufacturers.

Carbonize—The deposit of carbon upon the points of the spark plugs and the various internal portions of engine cylinder and exhaust passages.

Cell—An electrical cell, is a vessel complete with its contents, and a number of these form a battery, or a set of storage batteries. Each cell must contain positive and negatve plates, and some form of electrolyte.

Celluloid—A compound of camphor and gun-cotton. Its transparency and flexibility are its chief characteristics. Non-inflammable celluloid is now made for windshields.

Chauffeur; pronounced "Sho-fur."—Derivation, French, chauffeur, to heat. A chauffeur is a man in charge of a furnace or. boiler fire The first use of the word chauffeur was during the revolution of 1789, when bands of brigands heated "chauffeur" the feet of their victims in order to make them reveal the place where their money was hidden. The "chauffeurs" were stamped out during the Consular period. The word chauffeur was first applied to motor car drivers under the popular supposition that they had to tend a fire. On the French railroads the chauffeur is the fireman; the engine driver is the mechanician.

Chauffeuse—A woman chauffeur.

Chassis; pronounced "chas-say."—Derivation, French; a frame in wood or metal; the frame work of a wagon; later the term was applied to the frame-work of a locomotive; then to the longitudinal and transverse frame members of a motor car. By extension it also designates the whole of the mechanical portion of a motor car. More correctly, however, the word chassis should only apply to the metal framework receiving the engine gearset and controlling mechanism.

Change gears—The transmission or system of changing the gears in gear box.

Chamfer—A small channel or groove cut in metal or wood; corner beveled off.

Check-valve—A stemless valve; one which permits the passage of a fluid or gas in one direction only.

Circuit—The path of the electrical current; the conducting material, or wires.

Circulating pump—Pump used to circulate the cooling water. Operated by the engine.

Clutch—A device for connecting and disconnecting the engine from the transmission—usually placed in or on the inner face of the fly wheel rim.

Clutch pedal—The foot pedal which connects and disconnects the clutch.

Coefficient—A known quantity. That which cooperates with another variable or unknown quantity.

Coil and battery system of ignition—In a battery the electricity is obtained by chemical means instead of mechanical means, as when a dynamo is used. The coil has nothing to do with the generation of the electric current, its function being to "gear up," intensify, or increase the pressure or transform the low-voltage primary current into a high voltage secondary current to enable a spark to be produced across the air gap of the plug points.

See page 439 for Storage Battery Words and Terms. See page 898 for **English-French Dictionary.**
By referring to index definition of many other words can be found. See page 907 for Airplane Glossary

Combustion space—The space between the end of piston (when on upper dead center) and head of cylinder. That portion over the valve is also included. (see page 54.)

Compression—A term implying that the explosive charge of gas and air drawn into the cylinder on the suction stroke is subjected to a strong squeezing effect on the next stroke. The charge is pressed into a space about one-fifth the volume or space of that occupied by it on the suction stroke, equaling 55 lb. to 90 lb. pressure per square inch. See page 535.

Compensating Air Valve—Also termed auxiliary air valve; a valve which counteracts the tendency of an over rich mixture as the speed increases.

Compensating Gear—see "Differential."

Compression tap or cock—A small tap placed at the upper end of the cylinder, which can be opened to relieve the compression, to make cranking easier.

Concentric—The opposite of eccentric.—(see foot note page 146.)

Condenser—An important part in a spark coil or high tension magneto. (see page 229.)

Conductor—A material along which electricity will readily flow, such as copper, platinum, steel, and, in fact, all metals. Silver is the best conductor, but copper is only very slightly inferior. Carbon is a non-metallic element, but an excellent conductor much used in magneto construction for the brushes. The wires or cables of the ignition circuit are sometimes referred to as conductors or "leads."

"Contact breaker"—The interrupter on a magneto. Also applied to the interrupter arrangement on the "make and break" igniter.

Contact-screw—The small screw, having a platinum point, against which the trembler vibrates.

Contact sector—One of the Sectors in a timer or distributor. (see (U) fig. 2, page 270.)

Continuous or direct current.—This implies that the current flows in one direction. The direct opposite of alternating current.

Current—The flow of electricity.

Cut-out, Muffler—A valve opening into the exhaust pipe at a point between it and the muffler when opened permits the exhaust gases to escape through it directly into the atmosphere instead of being forced through the muffler. (see page 84.)

Cylinder en bloc—The cylinders cast together in one piece.

Cylinder priming cock—Same as compression relief cock. Usually placed in the head of the cylinder for injecting gasoline.

D

Dead rear axle—A rear axle that does not turn. Type usually used on double chain driven cars.

Demountable rim—A form of rim that can be taken off the wheel without deflating the tire.

Differential gear. See page 85.

Direct current—Electric current where the current flows continuously in one direction. Unlike "alternating" current—the opposite.

Distributor or Distributer—A special form of rotary switch, which directs the high tension current to the various spark plugs.

Dry battery—Called dry cells or primary cells. A series of primary cells which do not contain liquid electrolyte.

Dynamo—A generator of electricity. The dynamo is usually used on a motor car to light the electric lights and to recharge storage batteries and in some instances furnishes current for the ignition.

E

Earth connection, or "ground"—An inaccurate term when applied to the electric circuits of a motorcar. The car is insulated from the road by the tires, hence the "earth" is not used at all. What is meant is that the framework of the car is used as a return conductor so as to dispense with some of the wires.

E. H. P.—Electric Horsepower. 746 Watts.

Electrode—The insulated part placed in the igniter of a low tension system of "make and break" ignition. The center rod of a spark plug. (see fig. 2, page 218 and fig. 1, page 216.)

Electric ignition—Any form of ignition by which the mixture in the combustion chamber is ignited by means of an electric spark.

Elements—See fig. 9, page 446.

Electro-magnet—Any piece of metal (usually iron or steel) that is magnetized electrically. The opposite of a permanent magnet.

E. M. F.—Electro Motive Force. The voltage. The pressure. Tension.

En-bloc—Cast in one piece.

E. P. M.—Explosions per minute of a gasoline engine.

Exhaust box—See muffler and silencer.

F

Field—The seat of magnetic flow, between the pole pieces of a generator or motor.

Fierce clutch—See page 661.

Flash point—See page 201.

Fly wheel—A heavy wheel rotating without contact with anything save its axle, by the momentum of the periphery of which, an even running of the engine is obtained.

Flux, magnetic—Lines of magnetic force, that pass or flow through a magnetic field. (see page 267. Also for welding, see page 719).

G

Galvanometer—An instrument for measuring the presence, extent, and direction of an electric current.

Garage; plural, garages—Derivation, French. The word has been taken bodily, pronunciation and spelling, from the French language, in which it is a variation of the word gare, a station or terminal for either railway trains or boats. Garage, as a noun, means, in both French and English, a place in which motor cars are kept and is sometimes applied to shops wherein motor cars are repaired. The verb, to garage, means the act of putting a car in the garage building. Pronounced with the final g soft, the final a open and the accent upon the last syllable.

Gasoline or gasolene—(English, gas; Lat. al (eum) (oil). A light grade of petroleum.

Gear box—See transmission.

Gear ratio—The number of revolutions of the engine made for one revolution of the road wheels—this depending on which "speed" or gear is in use. Thus the high speed gear ratio may be 4 to 1. i. e., four revolutions of the engine to one of the road wheels.

Gear set—The transmission.

Governor—A device to regulate the speed.

Ground—Connection of electric wiring to frame of car or metal part of engine. The term was originally derived from the fact that with telegraph and telephone systems one wire was used, which was insulated from the ground. The other, or return wire to complete the circuit, the ground was used. A piece of wire was attached to an iron pipe and driven deep into the ground at each end of the circuit. This same principle is used in automobiles. One wire is insulated from the frame or metal part of car The frame is used as the return wire.

Gudgeon pin—The wrist pin also referred to as the piston pin, the latter being correct term.

H

Half speed shaft—The small shaft, revolved at one-half the speed of the crank shaft by means of any suitable gearing—the cam shaft.

High gear—Combination of gears ordinarily used in running. The highest ratio of gearing—on some cars 2½ to 1, others 3 to 4½ to 1.

High tension and low tension—See page 213.

Heat units—See page 861, 587.

Hydro carbon engine—A gasoline engine.

I

Idling—Refers to engine when running slow, and car is standing still.

Ignition cam—The small cam on the half-speed shaft which either causes a make and break of the current, or is notched to receive the nose of the trembler in timers of the mechanical vibrator type. (see fig. 2, page 220.)

Igniter has various meanings. On "make and break" ignition the part that makes the spark. On high tension it sometimes means the spark plug and others call the "commutator" or "timer" the igniter. The correct meaning should be the part that ignites the gas.

Increments—Gradual increase or increasing a specified amount.

"Indicated" horsepower or I. H. P. is the power delivered to the piston inside of cylinder and can be measured by taking an indicator diagram which shows the pressure of the explosion in pounds per square inch. From this the mean effective pressure during the stroke can be calculated. See page 535.

Induced current—The momentary current set up in a circuit, by the the proximity of wires conveying the primary current, but not connected with those wires.

Induction—An influence exerted by an electrical charged body, or by a magnetic field or neighboring bodies without apparent communication or connection.

Induction coil—A step-up transformer. An apparatus through which the primary current is made to pass close to the secondary wires, thus setting up the induced, or high tension current. (see page 221.)

Inductor—See pages 256 and 265.

Intensify—To increase, to render more intense—to intensify the voltage (pressure) means to increase the voltage.

Inlet valve cage—A housing used over an inlet valve. (see figs. 2 and 3, page 90.)

Inspiration—Means the same as "suction" or "intake" as, suction stroke, intake stroke, or inspiration stroke.

Insulation—The protection of wires, or leads, by some suitable material which is a non-conductor of electricity.

Insulator.—A material through which electricity cannot flow, for instance, porcelain, mica, india rubber, fibre, vulcanite, glass, celluloid, paraffin-wax, silk, shellac, steatite, slate, etc.

"Int."—When found stamped on a coil or terminal, means interrupter connection.

Integral—The whole made up of parts.

Intensity coil—See "Induction Coil."

Intermediate gear—Combination of gears intermediate in power and speed, between the low gear and the high gear.

Intermittent—Applied to a cam on the engine, meaning that the motion is not steady but at intervals.

Internal combustion engine—See page 58.

J-K.

Jump spark—A spark which jumps from one terminal of the secondary coil to the other. (see induction coil.)

Jump spark coil—Another name for induction coil, spark coil or high tension coil.

Jump spark plug—See page 235.

Kilometer—1000 meters or ⅝ of a mile.

Kilo-watt—1000 watts or 1⅓ horsepower.

L

Laminate—Built up of thin plates of metal, as shims or a "laminated core in magneto armature." (see fig. 6, page 258.)

Lapping—A term applied to the operation of grinding in or fitting rings, pistons, etc.

Limousine; plural limousines—Derivation, French. A motor car body with a permanent top projecting over the driver and having a protecting front. The name was originally applied to a cloak worn by the inhabitants of Limousine, an old province of central France. It was later extended to the covering of a carriage, and then to one type of enclosed motor car body. At present, the term often is applied to a complete car having a limousine body. (see page 16.)

Lines of force—Imaginary lines, in the direction of which it is assumed that the lines of magnetic attraction and repulsion pass or act. (see page 267.)

Liners—Metal plates, usually very thin, placed betwen two halves of a bearing so that by taking out a liner the bearing can be tightened.

Live axle—See page 31.

Low speed—The ratio of gearing in a transmission for running rear axle at the lowest speed.

M

Magneto—A device operated mechanically and driven direct from the engine and which generates electric current but "alternating" instead of "direct." There are two forms; the low tension and the high tension.

"Make and break" ignition—Low tension system. No spark plug used.

Manganese bronze.—Composed of copper, zinc and manganese. It makes very strong and tough castings. Forged front axles of this alloy are used on some American cars.

Mechanical efficiency is the ratio between the indicated h. p. and the h. p. available for useful work at the engine shaft.

Mechanician—A racing driver's helper. Also see page 594.

Mechanical equivalent of heat.—This is represented by the number 778, which is the number of foot pounds of work equivalent to one British thermal unit.

Mechanical valve—Applied to either the exhaust or inlet valves when operated by a cam or mechanical means. The exhaust valve is always mechanically operated, whereas the intake is sometimes opened automatically by the suction of the piston.

Mesh—Usually applied to the meshing of the teeth of two gears; for instance, the teeth of the large half time gear, in fig. 3, page 86, (G2), meshes with drive gear (G1) on crank shaft.

M. E. P.—See page 535.

Misfiring—Term applied to missing of one of the spark plugs.

Mono-block cylinders—Another name for en-bloc or all in one casting.

Motor—The engine or motive power. Technically it refers to an electric motor and should never be used when referring to the engine.

N

Negative pole—Minus sign—The point to which the current returns after passing through the circuit. Designated thus: (—)

Nickel.—Used in the form of an alloy with steel, viz., nickel-steel. For exhaust valve a high perecentage (20 to 25%) nickel steel is the most suitable material, as it effectively resists the intense heat and oxidizing action of the exhaust gases. Nickel is now the standard material for spark plug electrodes.

O

O—A small (°) placed along side of a figure expresses degrees, see page 93 for meaning of degrees.

Ohm—A unit of electrical measurement of resistance. The resistance an electric current meets in flowing through a conductor, is measured in ohms. (see page 207.)

Oscillate—A pendulum like movement, see connecting rod, page 645.

Otto, or four stroke "cycle," is an expression often used in connection with gasoline engines. It means that the power is developed during a complete cycle or four strokes, the principle first adopted in the Otto gas engine. The complete cycle comprises four distinct operations, one occurring at each half revolution of every stroke of the piston: thus (1) suction stroke, (2) compression stroke, (3) impulse or firing stroke, and (4) exhausting stroke.

P

Parabolic—Pertaining to, or formed like a parabola. One of the conic sections.

Periphery—That part of a wheel or disk farthest from its center. The circumference.

Pet cock—(also called relief cock and compression cock)—A small valve usually placed in head of cylinder or on carburetor.

Petrol—Gasoline.

Phosphor-bronze—An alloy mainly consisting of copper and small proportions of tin, lead and phosphorus, the proportion of the latter being very small. It is a very tough, hard-wearing alloy. Largely used for engine bearings.

Pinions—Gears that have the teeth cut right in the hub.

Platinum.—This very expensive metal (price ranging from $30 to $40 per oz., according to the market) is used for the contacts of the magneto. It is practically infusible (it has a very high melting point) and non-corrodible, and thus effectively resists the burning and oxidizing action of the electric spark. It is also used for the "leading in" wires of the electric bulbs used for car lighting, as its ratio of expansion (due to heat) is the same as glass. Sparking plug electrodes are, in a few instances, also made of it. Tungsten now extensively used instead.

Porcelain—The insulating material of the spark plug.

Poppet valve—The word poppet probably is a corruption of the name puppet applied to this type in England, on account of its resemblance to the popping up and down of the puppets in the old time Punch and Judy shows. (see fig. 1, page 88.)

Positive pole.—Usually indicated with a plus sign (+) means the positive terminal, or wire from which the current starts in an accumulator or dynamo. The carbon terminal of a primary or dry battery is positive.

Port—Openings in the cylinder for exhaust, inlet, water, or valves.

Pre-Ignition—Ignition occurring earlier than intended.

Primary battery—A series of either wet or dry cells depending upon chemicals for the generation of electricity, without charging from a dynamo or other battery.

Primary wires—The wires, or leads, conducting the primary, or low tension, current to the place, or places, where it is required for use.

Propeller shaft—The drive shaft from transmission to rear axle. (see page 50.)

Q

Quadrant—Usually applied to the quarter circle on which the spark lever and throttle lever is attached on the steering wheel.

R

Reciprocating—A back and forth movement applied to the action of the pistons in the engine.

Rectifier—An electrical device for changing alternating, into direct current.

Resistor—(ballast)—(see fig. 3, page 348.)

Retard—A decrease in the speed of. Usually applied to "retarding the spark," meaning to set the timer back so that the ignition will be later or slower.

Rotary—Revolving motion; opposite of reciprocating motion.

Rotary valve—See page 138.

R. P. M.—Revolutions per minute.

Rubber.—For tire construction rubber supplies come from various parts of the world. Amongst the finest grades is the well-known "Para" or Brazil rubber. South America rubber, generally is considered very good, but excellent supplies now come from Borneo, India, Ceylon, Federated Malay States, and, in fact, many other tropical lands. Pure rubber lacks certain important physical characteristics indispensable for tires, such as stability under change of temperature. Pure rubber becomes soft under the influence of heat, and hard and brittle when subjected to cold. The process of vulcanization renders the rubber proof against heat and cold, and also renders it tough and resilient, so as to possess "life" and vibration absorbing properties.

S

Scored—Marred by ridges or grooves. Usually referred to in connection with cylinders, (see page 653.)

Seats—That part of chamber upon which the valve rests. Applied to the valve in engine.

Secondary battery—A storage battery.

Secondary coil—The winding in which the high tension current is generated, which is quite distinct from the primary current.

Short circuiting—Providing a shorter path; placing a wire or other conductor, from positive to negative side. (see page 412.)

Shunt—To turn aside or branch off. (see pages 332 and 414.)

Silencer—See Muffler.

Sleeve valve—See page 139.

Spark—The spark which passes between the points of the spark plug.

Spark coil—A coil through which electric current is passed and intensified. (see fig. 1, page 220.)

Spark control lever—The lever on the steering column (usually the short one) attached to the timer. (see page 152.)

Spark gap—A safety device on a magneto to prevent the armature windings being strained or short circuited owing to a faulty spark plug or wiring circuit, also applies to gap between points of spark plug.

Starting crank—A crank for starting the engine.

Starting plug—A small brass plug which fits into an opening on the dashboard and closes the circuit. When removed, the circuit is broken.

Streamline body—See page 760.

Stroke—Usually referred to as the stroke of an engine, meaning the length of the up and down motion of a piston.

Stroke of engine—See Bore (and pages 543 to 546.)

Studs—Bolts, with threads cut on both ends, screwed into engine cylinders to fasten them to base, also used to fasten down cylinder heads. (see fig. 1, page 701.)

Symbols—See pages 541, and 356.

Synchronization—To time two or more sparks to occur exactly at the same instant or at a similar period in a given cycle of operation. (page 232.)

T

Tappet—A push rod connected between the cam and valve. (see fig. 2, page 92.) Also termed a plunger.

Throw—Usually referred to as the crank, or the part where the big end of the connecting rod attaches to crank shaft.

Thermal efficiency of an engine—See page 587

Tonneau; plural, Tonneaux—Derivation, French word meaning a barrel; a wooden vessel formed of staves and hoops and made to contain a tonneau (1,000 kilogrammes) of oil. Later, a horsedrawn carriage, known in England as a governess car, having a rear entrance. A similar type of body was first applied to a motor car by M. Huillier, of Paris, and by reason of its resemblance to a barrel and to the horsedrawn tonneau already existing, was known as a tonneau.

Torque—The word torque is a definite one and means the same whether referred to automobiles or any other piece of mechanism, and refers to the twisting or wrenching effect produced by the engine or motor See also page 535.

Touche—The small plug used in the switch to complete the electrical circuit when required. (French.)

Transformer—Another name for a high tension coil. An electrical device for transforming the current from a low tension to a high tension. An induction or secondary or high tension, double wound, coil.

Trembler—The small vibrating spring used for making and breaking the primary circuit of a coil. (see page 220.)

Tube ignition—A small tube, usually of platinum—having its outer end closed—is screwed into the combustion chamber. This tube is so placed that the flame of a blow-lamp, generally supplied from a separate and small tank of gasoline, acts upon it and causes it to become incandescent. Old method of ignition now out of date.

Tuning an engine—Extreme care and special adjustment—as tuning up a car for a race, etc.

Two-to-one gear—The gearing—usually consisting of two-gear wheels, one having exactly double as many teeth as the other, also called "timing gears" and "halftime-gears."

V

Valve-lifter—An additional lever by means of which the exhaust valve may be raised and kept out of action, thereby reducing the compression and preventing the creation of a vacuum within the cylinder, so causing the inlet valve to remain closed. Used extensively on aero and stationary gasoline engines. This term also applies to a "valve spring lifter," (see page 633.)

Vaporizer—An early form of carburetor valve. See page 141, fig. 1. The vaporizer is also a means of heating the fuel.

Venturi—Applies to the mixing chamber of a carburetor; Venturi shaped—(see page 152, figs. 2 and 3.)

Viscosity—The adhesive or glutinous characteristic of oils used for lubrication.

W

Watt—The unit of electrical power obtained by multiplying volts by amperes. (see page 207.)

Wet-Cell—A battery using a liquid solution.

White metal or anti-friction metal—An easily fusible alloy of lead, antimony, and tin used for "lining" re-metalling bearings.

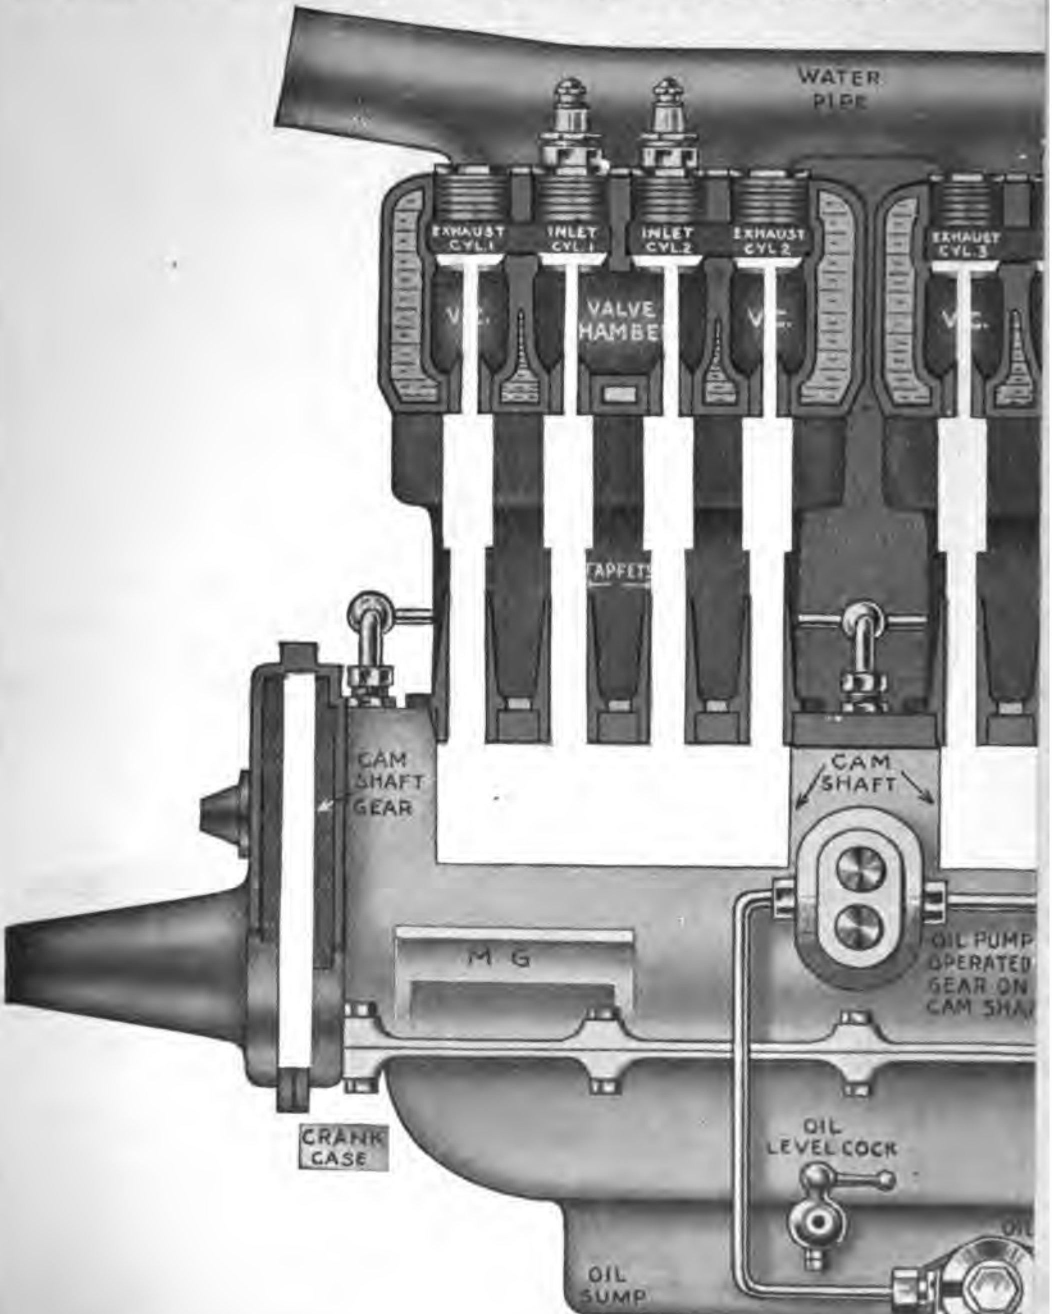
VALVE AND CAM SIDE OF 4 CY

Draw in the other side first—then the parts on this, the valve side of engine.

Valves—draw in the valve head in its seat or slightly raised where necessary, tak
116). Firing order we will say is 1, 2, 4, 3.

Valve springs are next, then valve spring retainers.

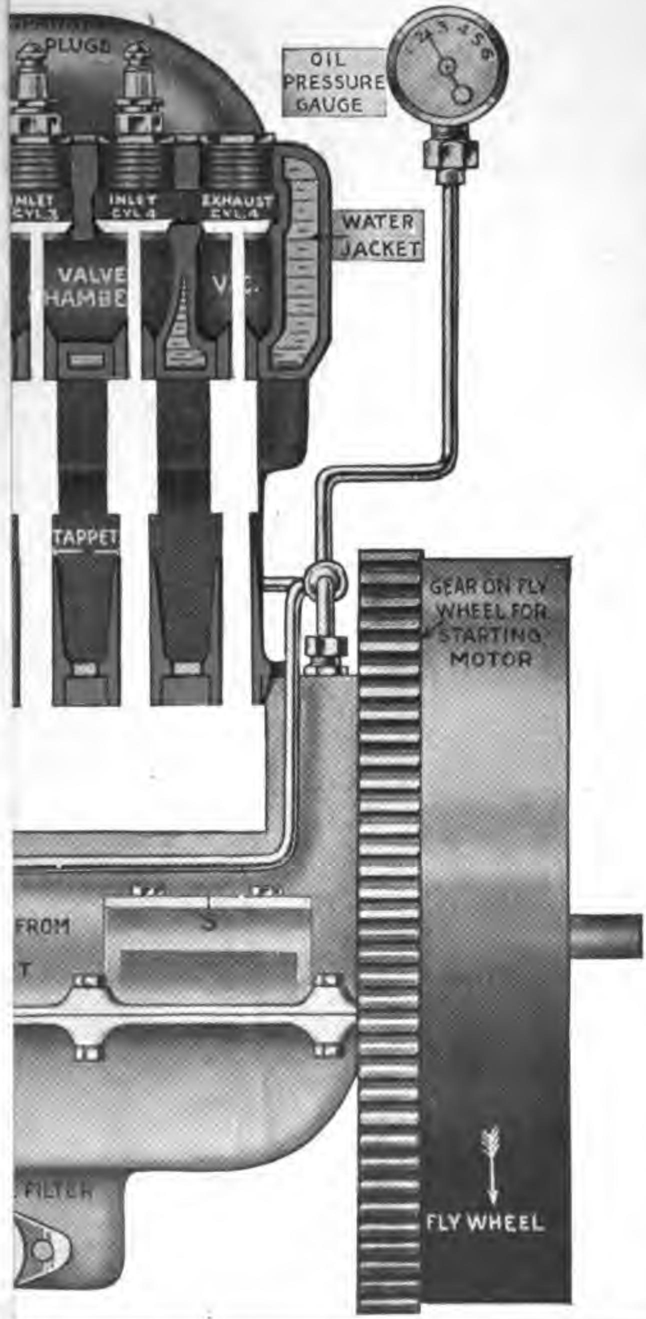
Cam gears should now be drawn, then **cam shaft** with its eight cams. Place cam
stroke, No. 2 just starting up on compression, No. 3 just starting up on exhaust



LINDER ENGINE—Draw in the Parts.

ing it for granted that No. 1 piston is just starting down on power stroke (see page

s in position, as near as possible as if No. 1 piston was just starting down on power , and No. 4 just starting down on suction stroke.



Valve guides are drawn **next**, then **valve plungers; on the** upper part of valve **plungers** place adjustment nuts.

Lubrication system of the forced feed principle **can now** be outlined—the oil **pump** being operated from the **cam** shaft. Show arrows **pointing in** direction of flow of oil.

Ignition—a magneto of the **high** tension type* can be **installed** or a battery and coil system.

If battery and coil system, place the ignition unit (as **per page** 342) on the generator **and place** generator on the bracket (MG). Chains usually run the **generator**—but in this case **we will** use gears.

Connect up the wires from timer to battery (place **a battery** below some where), **connect** cables from **distributor to** spark plugs for a firing **order** of 1, 2, 4, 3.

Starting motor—place a **starting** motor using a Bendix **drive** (see page 342—and **explanation** pages 326-331) on the **bracket** (S)—connect this **starter with** battery and switch.

*See illustrations, pages 310 and 266.

The F. A. Starting and Lighting System as Installed on Ford Sedans and Coupes.

Parts and Location.

The starting and generator system is a two-unit type and consists of the following parts: Generator, cut-out, combination switch, fuse, terminal block, ammeter, starting motor, storage battery, wire, headlamps with headlight bulbs and dimmer bulbs. The combination switch, ammeter, and priming button are mounted on a cowl.

The Starting Motor.

The starting motor is mounted on the left-hand side of the engine and bolted to the transmission cover. When in operation the pinion on the *Bendix drive shaft engages with the teeth on the flywheel, which is a ring gear with teeth cut in it and bolted to flywheel and held in place by the brass screws which hold the magnets—see fig. 5, page 864B.

When Starting Engine.

The spark and throttle levers should be placed in the same position on the quadrant as when cranking by hand, and the ignition switch turned on. Current from either battery or magneto may be used for ignition. When starting, especially if the engine is cold, the ignition switch should be turned to "battery." As soon as the engine is warmed up, turn switch back to "magneto." The magneto was designed to furnish ignition for the Model T engine and better results will be obtained by operating in this way. Special attention must be paid to the position of the spark lever, as a too advanced spark will cause serious back firing which in turn will bend or break the shaft in the starter.

The starting motor is operated by a push button, conveniently located in the floor of the car at the driver's feet. With the spark and throttle levers in the proper position, and ignition switch turned on, press on the push button with the foot. This closes the circuit between the battery and starting motor, causing the pinion of the Bendix drive shaft to engage with the teeth on the flywheel, thus turning over the crank shaft.

When the engine is cold it may be necessary to prime it by pulling out the carburetor priming rod, which is located on the instrument board. In order to avoid flooding the engine with an over rich mixture of gas, the priming rod should only be held out for a few seconds at a time.

If Engine Fails To Start.

If the starting motor is turning the crank shaft over and the engine fails to start, the trouble is not in the starting system. In this event release the button at once so as not to unnecessary discharge the battery, and inspect the carburetor and ignition system to determine the trouble.

If Starting Motor Fails.

If the starting motor fails to act, after pushing the button, first inspect the terminal on the starting motor, the two terminals on the battery and the two terminals on starting switch, making sure all of the connections are tight; then examine the wiring for a break in the insulation that would cause a short-circuit. If the wiring and connections are o. k. and the starting motor fails to act, test the battery with a hydrometer. If the hydrometer reading is less than 1.225 the trouble is no doubt due to a weak or discharged battery.

Operation of Generator.

The generator is mounted on the right-hand side of the engine and bolted to the cylinder front end cover. It is operated by the pinion on the armature shaft engaging with the large time gear (spiral gear).

The charging rate of generator is set so as to cut in at engine speeds corresponding to 10 miles per hour in high speed and reaches a maximum charging rate at 20 miles per hour. At higher speeds the charge will taper off, which is a settled characteristic of battery charging.

This operation of cutting in and cutting out at suitable speeds is accomplished by the cut-out. This cut-out is set properly at the factory and should not be tampered with.

Oiling.

The starting motor is lubricated by the Ford splash system, the same as the engine and transmission. The generator is lubricated by a splash of oil from the time gears. In addition an oil cup is located at the end of the generator housing and a few drops of oil should be applied occasionally.

When Tampering with the Ignition System.

The introduction of a battery current into the magneto will discharge the magnets and whenever repairing the ignition system or tampering with the wiring in any way, do not fail to disconnect the positive wire from the battery. The end of this wire should be wound with tape to prevent its coming in contact with the igniton system or metal parts.

An Ampere Meter

is located on the instrument board or cowl and reading is 20-0-20 which means, 0 or zero is in the center and 20 to the left or "discharge" side and 20 to the right or "charge" side. (see page 410 for explanation.) The needle is on the "charge" side, when the generator is charging the battery and "discharge" side, when the lights are burning and the engine not running above 10 miles per hour.

At an engine speed of 15 miles per hour or more the meter should show a reading of 10 to 12 amperes even with lights burning.

If the engine is running above 15 miles per hour and the meter needle does not go to the "charge" side, first inspect the terminal posts on the meter, making sure that the connections are tight, then disconnect the wire from the terminal on generator, and with the engine running at a moderate speed, take a pair of pliers or a screw-driver and short-circuit the terminal stud on the generator to the generator housing. If the generator is o. k., a good live spark will be noted. (Do not run the engine any longer than is necessary with the terminal wire disconnected.) Next inspect wiring from generator through the meter, to battery for a break in the insulation that would result in a short-circuit.

*The same principle as shown on pages 326, 331. See fig. 2, page 331. and note how spring is connected with sleeve. See page 577 for a **Digest of Starting Motor and Generator Troubles.**

For a description of a **Ford Mechanical Starter,** write A. L. Dyke, Granite Bldg., St. Louis, Mo.

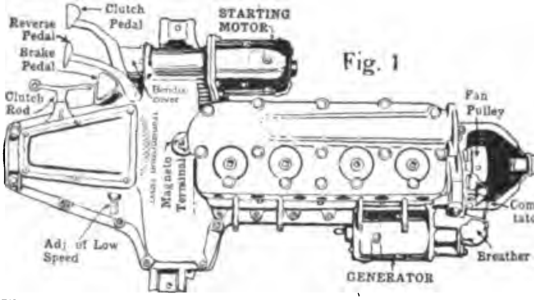


Fig. 1—Top view of Ford power plant.

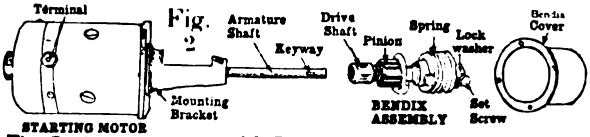

Fig. 2—Starting motor with Bendix drive parts removed from armature shaft.

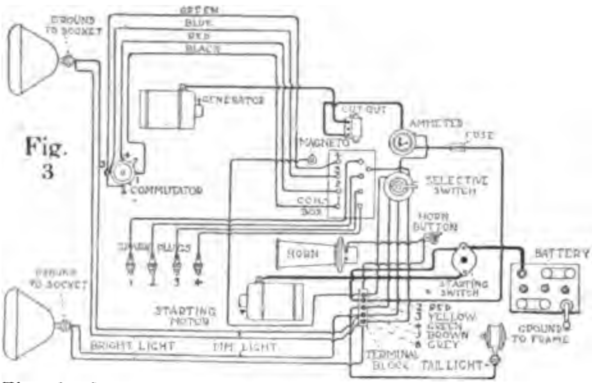

Fig. 3—Circuit wiring diagram. The "cut-out" is now mounted on the generator. See also, page 823.

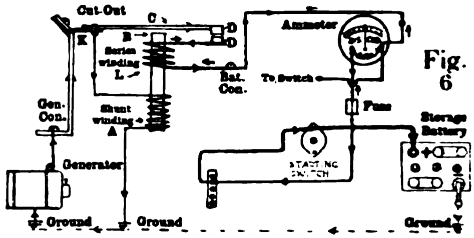
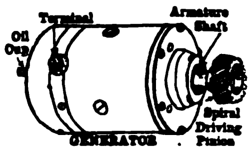


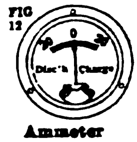
*Out-Out Action.

When engine is started and running slow, current flow from generator begins to build up magnetic strength in iron core (B), through fine wire winding (A). Note connection to battery is open at (D).

When car speed reaches 10 m.p.h. on high gear, generator current is then strong enough for (A) to magnetize (B), and blade (C) is drawn to (B), which closes contact points (D). Generator voltage is then 6.8 volts, or slightly more than battery (battery is 6 volts). Therefore generator charges battery with current passing through the coarse wire winding (L), through ammeter to battery. Generator current is now passing through (L) & (A) in same direction.

When engine slows down less than 10 m.p.h. generator voltage is then less than the battery voltage, therefore battery current begins to flow, or discharge in opposite direction (see outside arrows), through winding (L), and this is why it is called a "reverse current" cut-out. This action opposes generator current passing through (A), which is weak, with result that core (B) loses its magnetism, or is demagnetized and releases blade (C), through tension of spring (K), thus opening circuit between generator and battery. This action is repeated over and over as engine speeds up and slows down.





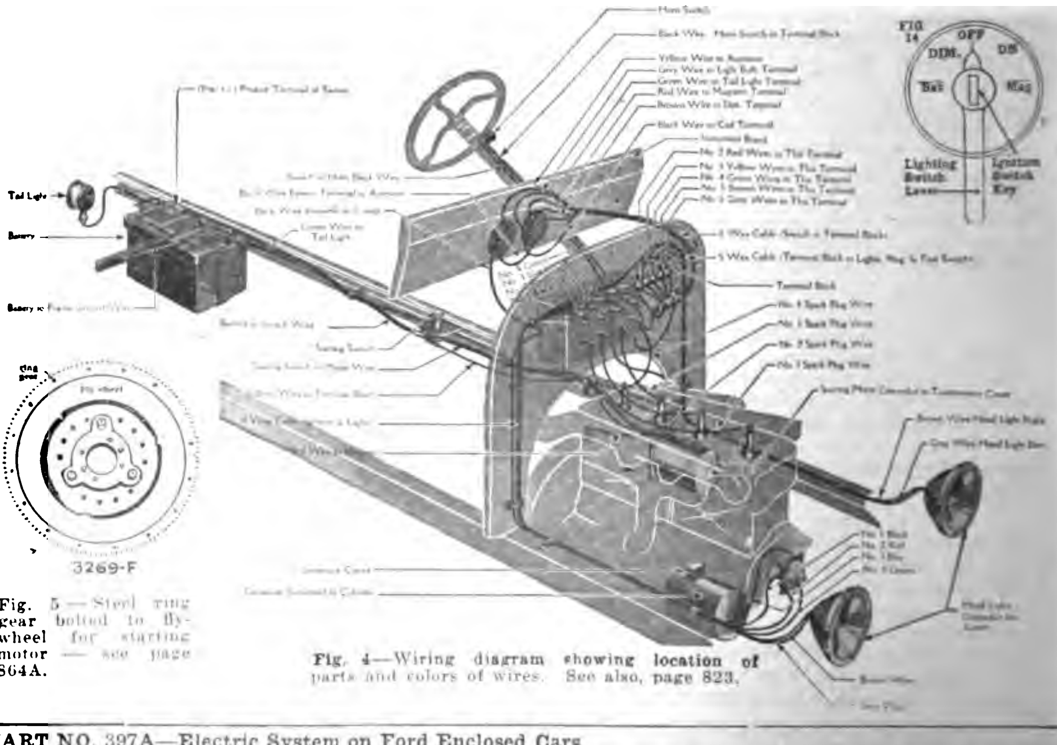


Fig. 4—Wiring diagram showing location of parts and colors of wires. See also, page 823.

Fig. 5—Steel ring gear bolted to fly-wheel for starting motor — see page 864A.

CHART NO. 397A—Electric System on Ford Enclosed Cars.

*See page 864A and a description of another cut-out which is similar on page 344. This type of cut-out is called a "reverse current" cut-out. Generator is a "third-brush" regulated type.

Lighting System.

The lighting system consists of two 2-bulb headlights and a tail light operated by a combination lighting and ignition switch located on the instrument board. The large or headlight bulbs are of 6-8 volt, 17 candle-power type, 2½ amp. The rear and dimmer bulbs are of 6-8 volt, two candle-power type, .042 amp.

All of the lamps are connected in parallel so that the burning out or removal of any one of them will not affect the other. Current for the lamps is supplied by the battery.

Do not connect the lights to the magneto as it will result in burning out the bulbs and might discharge the magnets. Illustration figs. 3, 4, show the different circuits and also the **ignition switch**, which is a key and **lighting switch**, a lever.

How To Remove Starter.

When removing the starter to replace transmission bands, or for any other reason, first remove the engine pan on the left hand side of the engine and with a screw-driver remove the four small screws holding the shaft cover to the transmission cover. Upon removing cover and gasket, turn the Bendix drive shaft around so that the set screw on the end of the shaft, as in fig. 2, is in the position shown. Immediately under the set screw is placed a lock washer, designed with lips or extensions opposite each other on the outside diameter. One of these is turned against the collar and the other is turned-up against the side of the screw head. Bend back the lip which has been forced against the screw and remove the set screw. As the lock washer will no doubt be broken or weakened in removing the starter, a new one must be used when replacing it. These washers may be obtained from the nearest branch.

Next, pull the Bendix assembly out of the housing, being careful that the small key is not misplaced or lost. Remove the four screws which hold the starter housing to the transmission cover, and pull out the starter, taking same down through the chassis—this is why it was necessary to remove the engine pan.

In replacing the starter, be sure that the terminal connection is placed at the top. If the car is to be operated with the starter removed, be sure to put the transmission cover plates in position. These plates may also be obtained from the nearest branch.

How To Remove Generator.

If it is found necessary to remove the generator, first take out the three cap screws holding it to the front end cover and by placing the point of a screw-driver between the generator and front end cover, the generator may be forced off the engine assembly. Always start at the top of the generator and force it backward and downward at the same time.

Plates may be obtained from the nearest branch to place over the time gear if the engine is to be operated with the generator removed.

To Operate Engine; Generator Removed.

If for any reason the engine is run with the generator disconnected from the battery, as on a block test, or when battery has been removed for repair or recharging, be sure that generator is grounded to engine by running a wire from the terminal on generator to one of the valve cover stud nuts. A piece of wire 1/16" or more in diameter may be used for this purpose. Be sure that the connections at both ends of the wire are tight. Failure to do this when running engine with generator disconnected from battery will result in serious injury to generator.

Battery.*

Is a 6-volt 13 plate "Exide", type 3-XC-13-1.

To Test Ford Generator.

Clamp generator lightly in vise (fig. 22). Turn armature by hand to see if it revolves freely, if it does, attach one wire from a 6 volt battery to bolt of vise (one generator terminal is grounded), touch other battery wire to generator terminal to see if generator will run as a motor. If it does, and draws less than 6 amperes, generator is probably in good condition. **If it draws more than 6 amperes,** take a piece of No. 00 sandpaper and hold it against the commutator until a bright surface is obtained. See page 404.

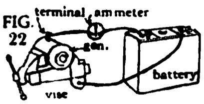
**Installing New Brushes.

Examine brushes and see that they are not too short and that they are clean and bear properly on commutator. If loose, heat will be generated.

*See pages 454, 455, 457, 458 "Care of Battery".

To fit new brushes cut a strip of No. 00 sandpaper. Pull the spring back (fig. 23) and pull brush up by pigtail after which spring is allowed to rest on brush. Insert the sandpaper, sand side up, per fig. 25, and hold it so it will conform to commutator and move it together with commutator back and forth under brush, the brush having been dropped on the sandpaper. Remove brush and see if it is properly seated to curvature of commutator and replace brush. Fig. 25 shows method of sanding the third-brush (3) and fig. 26, method of sanding the two lower brushes (1, 2).

FIG. 22



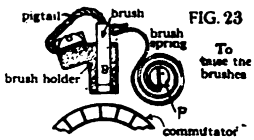


FIG. 23

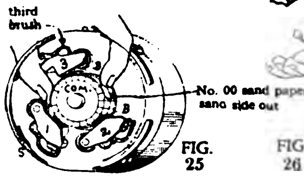

FIG. 25

FIG. 26

Setting Brushes.

The Ford generator uses the third-brush system of current regulation. When brushes seat properly the lower brushes (1, 2) should be set on the **neutral point.** Start the lower and loosen the three upper screws (S) which hold the brush-ring to the head. Raise the third-brush as per fig. 23. Connect battery wire to the generator terminal. If armature revolves, the brushes are not set on the neutral point. Turn ring against the direction of rotation until armature ceases to turn or until it revolves in opposite direction. If it turns in opposite direction, bring the ring back until armature will not revolve in either direction even when started by turning the shaft by hand. The brushes are now set on neutral point. Tighten the screws which hold ring to head; lower the third-brush (3) and try it for running. If it turns over properly, drawing less than six—preferably less than four—amperes, the generator should be assembled to engine, and proper connections made through cut-out to battery.

Setting The Third-Brush.

The next operation is to set the third-brush. The third-brush may be moved back and forth on the brush-ring. It is clamped to the ring by means of a bolt which is also used as a post (P. fig. 23) for the brush spring. To move the third-brush, together with its holder, loosen the nut on this post until the holder may be moved back and forth. The third-brush should be set in such a position as to give a charging rate of 10 to 12 amperes when the engine is running at about 20 miles per hour.

Changes on Engine.

The following changes have been made on engines of enclosed cars, to accommodate the starter motor and generator.

- **Transmission cover changed to take starter.** Ford No. is 3376B.
- **Cylinder block changed.** Ford No. 3000C.
- **Cylinder block front cover, changed.** Ford No. 3009C.
- **Cylinder block front cover liner.** Ford No. 3018.
- **Timing gear cover.** Ford No. 3017.
- **Flywheel with ring gear.** Ford No. 3269F. The ring gear bolts to flywheel and has teeth cut in it to take starting motor gear. See fig. 5.

Price of Coupe and Sedan.

Price includes the electric system, demountable plain clincher rims of 5 lugs and tires all 30x3½, and an extra rim or carrier. F. O. B. Ford Factory at Detroit and without war tax. Coupe $750; Sedan $875.

**See also, page 404, 405.

Cadmium Test of a Storage Battery.

Why Necessary.

The condition of a storage battery is usually ascertained by taking a specific gravity reading of the electrolyte, with a hydrometer as per page 450. A reading of 1,275 to 1,300 **being** usually considered as indicating **a** fully charged cell. While specific gravity readings with a hydrometer should always be made, yet they should not be relied upon entirely.

For instance, a battery which gave entirely satisfactory hydrometer tests, may show a rapid drop in voltage when in use, yet this condition could not be foretold by hydrometer readings alone, because the hydrometer readings would not tell us the condition of either the positive or negative plates, and it is their condition which determine the amount of energy in any battery.

We may also take a voltage reading of the entire battery per fig. 1, while current is being drawn from the battery which gave satisfactory hydrometer readings. This would tell us if the plates were not in good condition, but it would not tell us **which set of plates** was at fault, because the voltage reading includes all positive and negative plates, as per fig. 1.

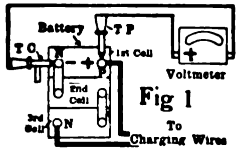

Fig. 1. Testing the voltage of all cells of battery, when battery is on charge and preliminary to taking a cadmium test.

If we took a voltage reading of one cell per fig. 1A, while battery is on charge, you can readily see that the test includes both positive and negative plates. Suppose the battery will not take a full charge, which set of plates is defective; the positive or negative?

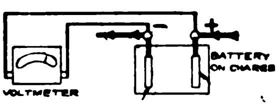

Fig. 1A. Testing one cell of battery when on charge and preliminary to cadmium test.

Therefore, to determine the condition of the positive and negative plates separately, we must make a test between each set of plates and some neutral substance. Theoretically, a number of substances could be used for the neutral substance, but for practical reasons cadmium is used.

*The Cadmium Outfit.

Cadmium is a metal, it looks like zinc, but is pure, because there is no other substance mixed with it.

A cadmium testing outfit consists of two copper test points, one **of which has a stick** of cadmium, about 3½" long and ¼" di., riveted to it, as per fig. 2, and a special reading voltmeter.

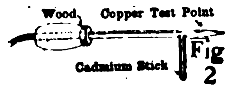

Fig. 2. The test-point, with the cadmium stick riveted to it. The cadmium is the part which is inserted in the electrolyte.

The cadmium test can be made while a battery is on charge or when it is being discharged. As a rule, **the test is made only near, or at the end of a charge, in order to determine if both positive and negative groups are taking the charge properly.**

The Voltmeter.

Any accurate voltmeter can be used, which gives readings up to 2.5 volts in divisions of .05 volt. The test point (TC, fig. 4) is connected to right hand terminal of the voltmeter and the test point (TC) with the cadmium on it is connected to the + terminal of voltmeter.

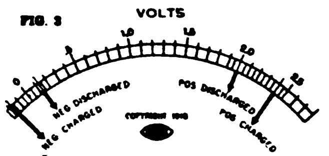

Fig. 3. Scale of dial on the cadmium test volt meter—one-half actual size.

As an example, however, we will use the face dial of a special made voltmeter manufactured especially for this purpose, which is one-half actual size, called the Ambu Cadmium Voltmeter, see fig. 3.

How To Test a Battery on Charge.

The charging current must be passing through the battery at normal rate when the **test** is made, and needle of voltmeter should **be** exactly on zero—this can be set with the **zero** adjustment. Then proceed as follows:

Measure the voltage of one cell, by holding one of the test points on the positive (+) and the other on the negative terminal (—), of the cell, as per fig. 1A.

If the cell is fully charged, the reading of voltmeter will be from 2.5 to 2.6 volts, depending on the age of the battery; **a new battery** giving a higher reading than an old one. (see also pages 410, 416.)

Cadmium Test of Positive Plates When on Charge.

Test the positive plates of one cell, by inserting the cadmium rod on test point (TC) in the electrolyte at vent (V) of cell, per fig. 4, being sure the cadmium does not touch the top of plates (a rubber tip at end of cadmium stick is provided on the Ambu set, to avoid touching.)

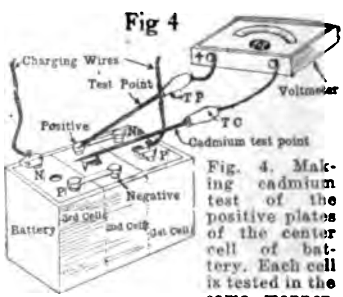

Fig. 4. Making cadmium test of the positive plates of the center cell of battery. Each cell is tested in the same manner.

Allow the cadmium to remain in the electrolyte for several minutes, until electrolyte has no further action on the cadmium. Then hold the pointed end of the other test point (TP) on the **positive cell terminal.**

If positive plates are fully charged, the voltmeter reading will be, to the right of line O, fig. 3, at least 2.35 and may be 2.42 or even 2.50, if battery is new. **Should reading be less than these, then the positive plates are not fully charged.**

Continue the charge, and if the positive plates will not then give a reading of at least 2.35 then positive plates are defective.

*This outfit can be obtained of A. L. Dyke, Elec. Dept., see page 864-I.

Cadmium Test of Negative Plates When On Charge.

Test the negative plates, by placing the test point (TP) on the negative terminal of the cell, per fig. 5.

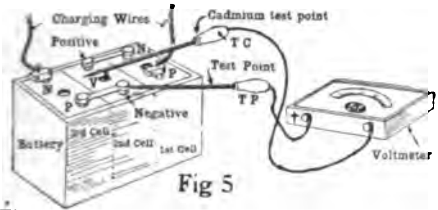

Fig. 5. Making cadmium test of the negative plates of the center cell of battery. Each cell is tested in same manner.

If the negative plates are fully charged, the voltmeter reading will be from—0.175 to —0.2, that is, the needle will move to the left of "O" line on the scale, fig. 3.

Should the reading be very nearly zero, or if the needle swings to the right of the "O" line (fig. 3), the negative plates are not fully charged.

Continue the charge, and if the negative plates will not give a reading of from 0.175 to 0.2 volts to the left of the "O" line on the scale, then the negative plates are defective.

Test the other cells of battery in the same manner.

The difference between the positive—to—cadmium readings and negative—to—cadmium reading is 2.595, the voltage of a fully charged cell while on charge.

Readings On Scale of Voltmeter.

This special voltmeter, fig. 3, page 864-D, has the "O" line near the left end of scale. The scale is marked especially for cadmium tests.

To the left of the "O" line is a red line marked "NEG. CHARGED." This line indicates the reading of —0.175 which should be obtained when testing new negative plates which are fully charged, that is, when making a cadmium test on the negatives, the pointer should move to this red line. If the pointer does not move as far as the red line, the negatives are not fully charged.

Similarly, there is a red line at +0.175 marked "NEG. DISCHARGED," at +2.00 marked "POS. DISCHARGED," and at +2.42 marked "POS. CHARGED."

Old cells will give readings which are not quite as high as those indicated by red lines.

Table of Readings
below give voltmeter and cadmium readings taken at hourly intervals on a battery during time it was being charged at a normal rate. Any healthy battery should not depart widely from these readings.

Hours on charge	Reading across cell-volts	Reading positive pole to cadmium-volts	Reading negative pole to cadmium-volts
0	2.10	2.25	+ .15
1	2.17	2.27	+ .10
2	2.19	2.28	+ .09
3	2.21	2.29	+ .08
4	2.23	2.31	+ .08
5	2.24	2.32	+ .08
6	2.25	2.33	+ .08
7	2.30	2.35	+ .05
8	2.48	2.43	— .05
9	2.60	2.50	— .10

How to Test a Battery on Discharge.

The battery should be discharging for this purpose, it may be connected to a number of lamps which will draw about 5 amperes from it.

Test the positive plates on discharge, in the same manner as before mentioned when testing a battery on charge.

If positive plates are discharged, they will give a reading of 2.00 to 2.05 volts.

If the hydrometer test shows that battery is discharged, and the positive plates give a reading greater than 2.05, they are not discharging properly or else there is an incorrect amount of acid in the electrolyte.

Test the negative plates on discharge, in the same manner as before mentioned when testing a battery on charge.

If the negative plates are discharged, they will give a reading of about 0.175 to the right of the "O" line on the scale.

If the negative gives a reading between "O" and 0.175, but less than 0.175 they are not discharging properly.

What To Do If Cadmium Tests Show Defective Plates.

Usually, when the cadmium tests show that either positive or negative plates are not taking a charge satisfactorily, it is only necessary to continue the charge until the proper readings are obtained.

If the specific gravity of the cell is not **from 1.275 to 1.300 when the cadmium tests show that both positives and negatives are fully charged,** some of the electrolyte should be removed and replaced by pure distilled water, or 1.400 specific gravity electrolyte, as the case may require. This is termed "balancing or adjusting electrolyte".

If the specific gravity reading is too high, add the distilled water.

If the specific gravity reading is too low, the 1.400 specific gravity electrolyte should be added until gravity is from 1.275 to 1.300.

Should the specific gravity reading indicate that a cell is fully charged, that is, if the hydrometer tests give readings from 1.275 to 1.300, but the cadmium tests indicate that both sets of plates are not fully charged, continue the charge to see if the proper cadmium readings can be obtained.

If it is impossible to obtain the proper cadmium readings on one or both sets of plates, these plates are defective.

If the operation of the battery on discharge is satisfactory, the only effect of the defective plates will be to cause the battery to lose its charge more quickly than normal, and thus require frequent charging.

If the operation of the battery on discharge is not satisfactory, however, the battery should be opened, and the defective plates repaired, or new plates put in.

Pointers to Remember When Making Cadmium Tests.

(1) **Remember that current must be passing** through the battery when you make the **cadmium tests.**

(2) **The temperature of the electrolyte should** be about 70° F. when **cadmium tests are** made, if accurate results are desired.

(3) **Do not send out a new battery unless the hydrometer readings are from 1.275 to 1.300, until the positive-to-cadmium tests give at least 2.40 volts, and the negatives-to-cadmium test give about—0.175 volts.**

(4) **Do not scrape off the coating of sulphate which forms on the cadmium.**

(5) **Do not allow the cadmium to become dry after you have made tests with it. Keep the cadmium immersed in a glass of pure distilled water, or dilute electrolyte.**

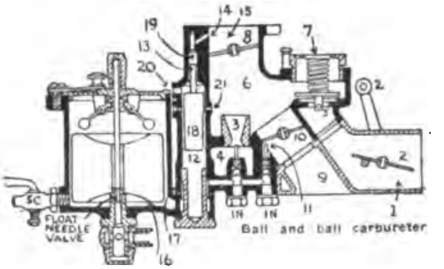
(6) **Be sure to get good contact when you hold the sticker on the battery terminal. Bear down on the handle so that the point of the sticker digs down into the terminal.**

(7) **If both positive-to-cadmium and negative-to-cadmium readings are very nearly zero, the cell is short circuited and must be inspected for excessive sediment, or defective separators.**

(8) **The end of the cadmium rod must not be allowed to touch the tops of either set of plates, as this would give worthless readings.**

Ball and Ball Carburetor.

First or primary stage, when starting and usual running conditions: 1 is the hot air passage of the primary carburetor containing the choke valve 2. 3 is the primary venturi throat connecting the hot air passage with the mixing chamber 6, and containing the gasoline jet 4. 5 is another fixed air regulating orifice connecting the hot air passage 1 with the mixing chamber 6, and provided with a spring-opposed idling valve 7 arranged to control the air when small quantities only are being used. 8 is a throttle valve of the usual type. The parts so far described constitute the first stage.



Ball and Ball Carburetor, as used on the Peerless, Studebaker, King, Mercer, Oldsmobile.

Second stage, or when throttle is wide open for full power: 9 is an air passage leading from the external air to the mixing chamber 6, and it contains the butterfly valve 10, arranged to control the flow of air through this passage. 11 is a gasoline jet arranged to discharge gasoline into the passage 9, when the valve 10 is opened, causing the gasoline jet 11 to be acted on by the suction of the mixing chamber 6. The air passage 9, with the gasoline jet 11, constitutes the second stage which is brought into action by opening the butterfly valve 10. A connection between the butterfly valve 10 and the throttle valve 8 (not shown) is so arranged that when the throttle valve 8 is nearly wide open, the further opening of this valve throws the valve 10 wide open. At all other times, the valve 10 is held closed by a spring (not shown).

From the foregoing description, it will be seen that under all the usual running conditions of the engine, the primary carburetor, or first stage only, is in service, and the second stage comes into service only when the throttle is thrown wide open for full power. The effect of this arrangement will be described further on.

Pick-up device; continuing the description, 12 is a cylindrical chamber with an extension 13 of reduced diameter connected by the passage 14 with the chamber 15, above the throttle valve. The chamber 12 is connected with the float chamber 16 by means of the restricted passage 17, so that the gasoline at all times in this chamber 12 stands on a level with the level in the float chamber. 18 is a loosely fitting plunger with an extension 19 on its upper end, forming a piston in the chamber 13. An atmospheric opening, 20, is located in the wall of chamber, 12, and a passage, 21, leads from chamber, 12, to the mixing chamber, 6, through which passage, air is constantly drawn into the mixing chamber.

Operation of the pick-up device: it will be seen that in the operation of the engine, when the throttle is closed, the vacuum of the manifold acting on the piston, 19, causes the plunger, 18, to rise to its upper position, thus closing the passage to the chamber, 15. The space below the plunger, 18, is now filled with gasoline from the float chamber, and the mechanism is ready for action.

The opening of the throttle, 8, breaks the vacuum in chamber, 15 and releases the plunger, 18, which falls and displaces the gasoline underneath the plunger, causing it to flow into the space above the plunger, where it is quickly discharged through the passage, 21, to the mixing chamber, thus augmenting the normal supply of gasoline and causing a rich mixture to momentarily enter the cylinder. This develops a strong pick-up.

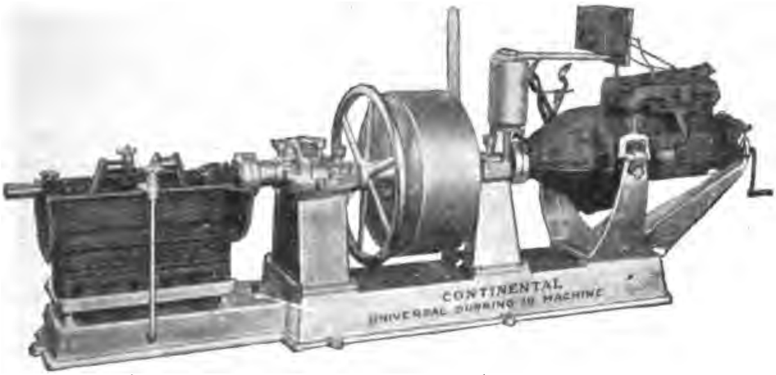
Adjustments: There are no adjustments after size of jets are determined.

Air regulation: Amount of air is controlled by valve (2) which is operated by the choke rod handle on dash or steering post. For cold weather this valve (2) should be closed to draw in a rich mixture. Immediately engine starts push it down part of way until engine is warm, then close entirely. Don't open throttle at all when (2) is closed and don't run with (2) closed any more than possible.

Troubles: Dirt under float valve will cause dripping; unscrew cap over float needle valve and give it a few turns. Water or dirt may lodge in small openings and this is indicated by popping and missing. Close valve on gravity tank, remove four nuts at bottom and clean jets.

Continental Shop Equipment

—THE EFFICIENCY STANDARD—



CONTINENTAL BURNING-IN-MACHINE.

Efficient Shop Equipment is as necessary to the Garage and Service Station as efficient machine tools are to the manufacturer. In fact, the time has come when the manufacturers of automobiles are requiring their Service Stations to install efficient equipment that will enable the Service Station to do a higher quality of work at a less price.

Days of the hammer and screw driver are numbered. Such concerns will either be forced to install modern methods and equipment or see their business gradually slip away to the wide awake dealer. Also it's a matter of labor saving devices that conserves the energy of men. Hard work, uncomfortable positions and poor tools make men tired, and tired men certainly can not be expected to turn out good work.

The right kind of labor saving equipment is an investment and an investment that pays back dividends. No repair shop can feel, therefore, that it can not afford the right kind of equipment.

The Continental line of Shop Equipment includes the labor saving devices listed below, cuts of a few are shown on this page, and this equipment is recognized by the greater percent of the leading manufacturers and by the entire automotive industry as "The Efficiency Standard."

Every Repair Shop and Service Station will find many of our labor saving devices of such value to them that they can not be replaced, and you should write today for your copy of our big catalog that shows the Continental line of Shop Equipment.

WESTON DIRECT CURRENT VOLT AND AMMETERS.

The most profitable work of Automobile Repairing is that of electric work. After studying the subjects of the different electric systems in this book, and the principle and construction of the Weston meter as shown on page 414, then diagnosing troubles page 416, and tests on pages 402, 403, 406, 410, 418, 424, anyone ought to be able to diagnose and remedy almost any electric trouble—if equipped with the proper Testing Instruments and the Wiring Manual.

Weston Model 280 Service Station Combination Volt-Ammeter.

This instrument (fig. 1) is the instrument used as an example on pages 402, 403, 406, 410, 416, and will test every part of the automobile electric system, from current consumed by starting motor, to testing individual windings on generator armatures. The instrument is fully explained on page 414.

Fig. 1—Weston Model 280 Combination Volt-ammeter (M) with case (C), three shunts (S), cables (W).

Ranges of readings are: 30 volts, 3 volts and .1 volt (100 milli-volt), 300 amperes, 30 amperes and 3 amperes.

The 30 volt range is useful for determining the voltage of generator or battery, per page 410 and tests per pages 416, 406.

The 3 volt range is of service in testing the individual battery cell, per fig. 1, page 416.

The .1 range may be used to test the individual armature windings, per page 402.

The 3 ampere range is of value in testing the current required by single lights.

The 30 ampere range will denote the current required by a complete lighting circuit, or the magnitude of leaks.

The 300 ampere range is useful to determine the starting motor current, per page 410.

The foregoing are merely a few of the tests that may be made with this instrument.

Price, including book of instructions showing how to make practically any electrical test of starting and lighting systems, including 3 shunts, cable, etc. $41.25
Imitation leather case, extra 8.00

Weston Model 301 Voltmeter and Ammeter—Separate. For Average Garage Work.

If you are unable to invest in the instrument above, then at least equip yourself with the following volt and ammeter.

Model 301 voltmeter with a reading, "0 to 15" volts, for testing cells of a storage battery, per V2, page 410 and figs. 1 and 2, 416 and for testing generator voltage per V1, page 410, 406, etc.

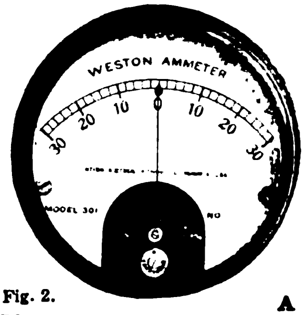

Fig. 2.

Fig. 2: Model 301 ammeter with "0" in center and reads to 30 amperes to the right or left, see page 410.

Model 301 voltmeter reads 0 to 15 volts and is same size and style. Di. 2½".

Model 301 ammeter with a reading, "30-0-30" for testing the amount of current flowing to battery from generator, or the quantity of current consumed by all of the lights or individual light circuits, testing the horn per page 418, igniton, grounds and short circuits. The current consumed by starting motor cannot be tested with this instrument. It will test up to 30 amperes without the use of external shunts. The shunt is inside of meter up to 30 amperes. See page 410 for meaning of 30-0-30.

Price of model 301 volt or ammeter (both round pattern as shown in fig. 2) $8.50

These instruments (models 301) were primarily designed for use on the dash or cowl of an automobile and the model 301 ammeter is just the instrument to replace "indicators" and defective ammeters, or to place on the dash of a car not equipped with an ammeter.

A Complete Electric Testing Equipment.

If you intend to do all kinds of electric work and specialize on this work, then I would advise that you obtain the Model 280 Combination Voltammeter and the **Cadmium Test Outfit,** page 864I, and the **Wiring Manual,** page 864F. You will then be completely equipped.

A Portable Electric Testing Stand.

If however, you wish to make the average tests around a garage, then you can purchase the two models of 301 instruments mentioned above, and mount them on a portable stand and rig up a very serviceable outfit.

Fig. 8, page 864-J, shows a rough sketch of how a portable testing stand can be made. The illustration is rather exaggerated but will serve the purpose of the idea.

—continued on next page.

Address all orders to A. L. Dyke, Electric Dept., Granite Bldg., St. Louis, Mo.

We repair Magnetos, Generators, Starters, Coils, etc. Send prepaid and we will test out and advise cost.

—continued from page 864-H.

The cables are flexible insulated wire with test points or clamps on one end and plug connections at the other end, like those used on telephone switchboards.

The plug receptacles can be mounted into the base of the stand and connected as shown, with meters, battery and test lamp, and in this way one set of cables can be used for all tests. A record sheet (R), can be placed on stand with thumb tacks, in order to keep a record of the readings.

An example of how the cables are plugged into different holes for different uses are as follows:

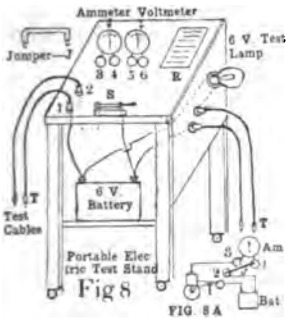

Fig 8 FIG. 8A

To use storage battery for any purpose, as testing a lamp or horn, or to connect to the battery side of a Ford ignition coil to run engine on the battery, while testing magneto, as per page 864J, place cable plugs in 1 and 2 and close switch (S) and use ends of cables.

To test amperage of a lamp bulb or horn; connect jumper (J) from 2 to 4, per fig. 8A. Then place cable plugs in 1 and 3. Touch test points (T) to lamp or horn. Note ammeter will then be in series.

To test generator output. Place cable plugs in 3 and 4 and place meter in series with circuit as is the dash ammeter page 410, or disconnect wire at terminal of generator and connect one test point (T) with generator terminal and other with the wire disconnected. This will place the ammeter in series with the generator circuit.

To test voltage of a generator, per V1, page 410, or of a **batery,** per fig. 1, page 416, or for any other voltage tests; place cable plugs in 5 and 6 holes or receptacles.

Note. It is advisable to place a 30 ampere, glass type fuse between plug receptacle 4, and ammeter, for the purpose of protecting the ammeter from accidental burn-out through overload or otherwise.

Other testing outfits can be added to this portable stand, as the spark plug test outfit, page 710, fig. 17 and page 418 and the battery test outfit, per page 474. In fact there is no limit as to how elaborate one can devise a stand of this kind, and in one shop, the stand is mounted on small steel wheels.

A test lamp outfit, for tests as shown on page 418, 403, 402, is shown mounted on this stand. Note the lamp is in series with the battery. The same cables can be used here.

THE CADMIUM TESTING OUTFIT

For Storage Batteries.

An ordinary voltmeter and a hydrometer will tell you if the battery is charged or discharged and you can also determine with a voltmeter if the plates are in good condition as explained on page 864-D, but **neither the hydrometer or voltmeter will tell you which set of plates are defective.** The **Cadmium test,** in connection with a **special reading voltmeter will tell you instantly.** See pages 864-D and E.

Usually, when a battery shows full charge with a hydrometer or voltmeter, when charging, yet drops or loses its charge quickly when in use, the trouble is with one or more sets of plates, either the "positive" or "negative," in one or more of the cells. In order then, to save disassembling all cells to find the defective plates (probabilities are you would not tell accurately even after disassembling) the **Cadmium Test** will tell you **instantly** where the trouble is.

If you propose doing battery repair work, you can turn out better work because you should never let a battery go out of your place unless the hydrometer readings are from 1.275 to 1.300; until the positive-to-Cadmium tests give at least 2.40 volts, and the negatives-to-Cadmium test gives about 0.175 volts.

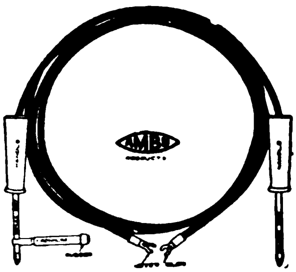

Fig. 1. Cadmium Leads and Test Points.

Fig. 1. The two **test points** are attached to flexible wire cables or "Leads." One of the test points has a piece of cadmium riveted to it. See page 864-D, for explanation of use.

Fig. 2. Special Reading Voltmeter.

Fig. 2. The special reading voltmeter used for making cadmium tests. Note the scale is calibrated showing exactly where needle should be when testing either the positive or negative plates—see page 864D.

Price of Cadmium Outfit.

Price, complete outfit, packed in a convenient case with complete Instructions including Voltmeter and Cadmium Leads with Test Points, per figs. 1 and 2 .... $26.50
Voltmeter alone, per fig. 2, ... **$22.50**
Cadmium Leads with Test Points if purchased separately, per fig. 1, only .... $ 4.25

Address all orders to A. L. Dyke, Elect. Dept., Granite Bldg., St. Louis, Mo. We repair Magnetos, Cells, Generators and Starting Motors—send your repairs to us, if you are not equipped.

FORD MAGNETO TESTER.

The Ford magneto generates "alternating" current. An ordinary "direct" current meter as explained on page 864-H and I, will not operate. Therefore a special meter per fig. 6 is designed for testing the Ford magneto.

If the engine will not run at all and the ignition is the fault, an easy way to determine if the cause is due to the magneto, is to connect a storage battery, or five or six dry cells to the battery side (B) of coil, per fig. 8, and turn switch to B, or right side.

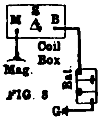

FIG. 8

If the engine then starts, and runs satisfactorily, but will not start on the magneto, with switch to the left, or M side, then you may know that the magneto is not supplying current. It may be due to dirty or loose magneto terminals T, (see fig. 7 below and page 805), or a weak magneto, due to weak magnets, or grounded magneto coils.

The Ford magneto can be tested with a special magneto tester, as per illustration, see figs. 6 and 7. This instrument is nothing more than an ammeter, but one provided with a "reactance coil" (R) fig. 7, which enables the meter to indicate a constant current at all engine speeds. In other words, the meter is so designed, it will indicate if magneto is giving its proper output at any speed of engine while testing.

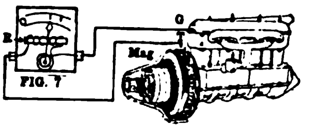

FIG. 7

This instrument can be used to test the strength of the magneto while engine is being run on a battery—if engine fails to start on magneto. If engine starts on magneto, but continually misses and is not due to other causes, then the tester can be used to see if magneto is delivering its proper current—while engine is being operated on the magneto. The connection for testing would be the same in both cases, per fig. 7, except, when running on battery, the wire from ignition coil to magneto is removed and switch placed on B side fig. 8.

The tester is a great help when assembling magneto on the bench. The "air-gap" can be adjusted to the point of greatest output, if you have the meter to test with as you assemble. The fly wheel can be turned by hand fast enough, so that instrument will give a steady reading.

"Air-gap," is distance the magnets are from core of magneto coils (see fig. 91, pages 805, 806.) This should be 1/32". If further away the amperage and voltage will be less; if closer, it will be greater, but **there is a liability of the magnet striking the coil core.**

To test air gap space and strength of magneto on car: (1) Test output of **magneto** with Tester, fig. 6, with engine **running moderate** speed; (2) Remove **transmission cover** and place a thickness gage, 1/32", **between magnet** and coil core. If gap is 1/32", **but magneto** has tested out as **weak, magnets need** recharging; (3) After **remagnetizing the** magnets (which can be done without **taking** engine down, see below), then test **magneto** again with engine running moderate **speed.** The tester should show **strong, if not, then** the probabilities are the **magneto coil is** short circuited.

If some of the magneto coils become short-circuited, or if magnets are weak, the tester will read low. In other words it tells you instantly, without removing the magneto from engine, if the magneto is in proper condition. If not in proper condition then it is time to take magneto out and remedy the trouble. If it tests o. k. then it is time to look elsewhere for the trouble and you will thereby save the time of having to remove the magneto in error.

The meter scale is very simple, it has two readings, see fig. 6. One marked "1914," meaning that all magnetos **before 1915, the** needle should come to this mark. **The other** is marked "1915," **meaning that all cars after 1915, the needle should reach this mark.** (The Ford magnets were enlarged in 1915).

If the needle fails to reach this mark, then remagnetize the magnets without removing from engine, as explained on page 819 and below. If then, the magneto fails to test up to this mark and the missing still occurs and is not due to loose terminals, and runs satisfactorily with a battery, then you may know you have a "grounded" magneto coil, and magneto must be removed, defective coil located, another put in place and then "air-gap" clearance given as per above.

Fig. 6. Ford Magneto Tester. Note how the scale is marked. See text.

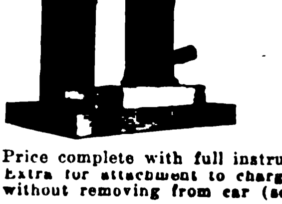
This device is one of the most useful accessories a Ford repairman could possess.

Price with full instructions $11.00

IGNITION COIL TESTER AND MAGNET REMAGNETIZER.

Ford Ignition Coil Tester: Consists of base, switch and ammeter. Coil should show a reading of about 1 1/3 amperes and a continuous spark across 1/4 in. gap. Full instructions. Price complete ... $6.00

This outfit will assist you in testing and adjusting ignition coils accurately.



Magnet Re-magnetizer. This outfit consists of a powerful electro-magnet mounted on wood base with switch and two binding posts. Operated from a 6-volt or 12-volt storage battery or dry cells. Will charge all magneto magnets

Price complete with full instructions $8.50
Extra for attachment to charge Ford magnets without removing from car (see page 819) ... $1.00

Address all orders to A. L. Dyke Elec. Dept., Granite Bldg., St. Louis, Mo.

Only "direct" current can be used to charge storage batteries, but in most towns and cities only alternating current is available.

There are three methods of charging batteries where only alternating current is available:

1: **By the use of a Rectifier,** as explained on pages 462, 463 and as advertisement, page 864-L.

2: **By the use of an electric motor which will operate from alternating current and then have this motor drive a dynamo or generator** which will generate "direct" current, from which current the battery is charged. This motor and generator is then "direct connected" on the same base and is called a **Motor-Generator Set.**

3: Instead of an electric motor being used to drive the generator, this **direct current generator can be driven by belt power** from a line shaft or gasoline engine or other power—per page 462.

Where a limited amount of battery charging is to be done, the Rectifier per page 864-L is recommended.

Where many batteries are to be charged, the Type 9G Motor-Generator Set, shown below, is recommended.

Type 9G Motor-Generator Set

is shown in fig. 1, and consists of the following parts:

1—**1¾ h. p. motor** to be operated from alternating current. This motor can be supplied to operate from any voltage or phase and this information should be obtained from your local electric plant when writing to us.

1—**Generator or dynamo,** which is connected to the above motor and generates "direct" current. The generator is of 1KW (one kilowatt) capacity, or 38 volts at 30 amperes.

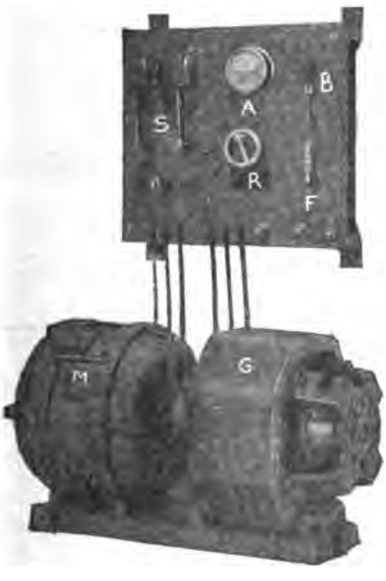


Fig. 1—Type 9G, St. Louis Motor Generator Set.

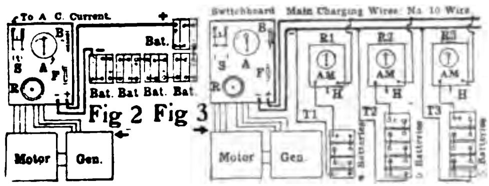
1—**Switch-board,** also called "charging panel;" parts of which are: a slate base, on which is mounted motor switch (S), which is connected with the alternating current source and the motor. Ammeter (A) is connected between generator and battery being charged and indicates quantity of current flowing to battery when charging. Field rheostat (R), connects with field winding of generator and regulates the quantity of current which can be made to flow to battery, or batteries being charged.

Fuses (F) are provided to protect generator and battery circuit and motor. B is the switch to generator and battery.

The type 9G motor-generator set will charge from 1 to 5 batteries in series at any amperage rate up to 30 amperes, by throwing in or out the resistance of field rheostat (R). Fig. 2, shows the connections when charging 5 batteries or less number.



As many as 20 batteries can be charged at one time, with this Type 9G, by adding Auxiliary Rheostats.

For instance, suppose it is desired to charge 14 batteries. It will necessitate three different charging lines and the use of three auxiliary Rheostats, as R1, R2, R3, fig. 3.

Suppose you desired to charge 4 of the batteries at 10 ampere rate and 5, at 6 amperes and 5, at 4 amperes. You will readily see that the current which would be drawn from generator would be 20 amperes, as adding 10, 6 and 4 we have 20 amperes. Therefore, we will connect an auxiliary rheostat R1, as shown. In this way we establish an independent charging line. Then to terminals T1 of this line, the 4 batteries to be charged at 10 amperes are connected in series. Then connect 5 batteries in series to auxiliary rheostat line R2, at terminals T2. Then the other 5 batteries connect to R3 terminals T3.

Place each rheostat handle (H) of R1, R2 and R3, so that all resistance is "cut-out." Then set the charging rate of generator, by moving shunt field rheostat on switch-board until ammeter (A), on switch-board, shows 20 amperes. Then note the reading on each of the ammeters (AM), on the auxiliary rheostats. A little resistance can then be cut in or added to the line that is taking most of the current until each of the 3 lines is cut down to the proper amount of current at which it is desired to charge each lot of batteries.

Price of Complete Motor-Generator Set, Type 9G, including switch-board, motor and generator **$246.00**

The Auxiliary Rheostat

As per fig. 4 and 3, are supplied separate, including slate base, ammeter in front and resistance coils in rear, which are made of resistance wire, wound on asbestos board and placed about ¾-inch apart, lengthwise on back of slate. The resistance is cut in or out with handle (H). The ammeter on rheostat indicates charging rate on that particular rheostat line, whereas the ammeter on switch-board indicates total amperes to all lines, or to 1 or 5 batteries if charged without this auxiliary rheostat. The maximum carrying capacity of auxiliary rheostat is 10 amperes.

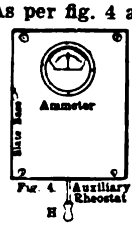


Fig. 4. Auxiliary Rheostat

Price, each **$7.70**

Type 9G Direct Current Generator

Can be purchased without the Motor but with a pulley, from which it can be operated from a line shaft by belt power, per page 462, or by a gasoline engine or otherwise. Speed of generator is 1800 r. p. m.

Price 9G Generator with switch-board, pulley . $165.

The 9R Switchboard For Direct Current

Can be purchased separate where you have your own direct current dynamo (generator). **This switch-board** (fig. 5) consists of a square slate panel 15½"x13", mounted on cast iron brackets to fasten to wall. On back of panel, the resistance is mounted with 9 taps (see page 464, fig. 11, for meaning and purpose of "taps"), which are controlled by handle in front. An ammeter to show amount of charging current and the controlling lever makes contact with resistance taps, regulating the charging current so that from 1 to 9 batteries may be charged at one time in series. The normal charging current is 6 amperes. The switch, with fuses for connection to dynamo is mounted in front.

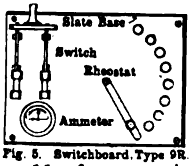

Fig. 5. Switchboard, Type 9R.

Price **$22.00**

RECTIFIERS—For Charging Storage Batteries.

Type MU vibrator rectifier (see illustration); will transform alternating current to direct, per pages 463 and fig. 2, page 465.

Each rectifier (per illustration), will charge 1-6 volt battery at 6 amperes, or a 12 volt battery at 3 amperes from the lamp socket of any alternating current lighting circuit.

You can purchase as many of the rectifiers as you have batteries to charge. In other words, purchase one now and as the business grows purchase more.

Price complete with ammeter, to operate from 110 volt 60 cycle current **$22.00**

For 220 volt, 60 cycle add $2; if for 50, 40, 30 or 25 cycle add $3.

(Ask your local electrician what cycle.)

WE REPAIR MAGNETOS—Also Coils, Generators, Starting Motors, Etc.

Send defective Magnetos, Generators, Starting Motors, Coils, etc. to us prepaid, and we will test out and advise you the cost of repair before proceeding with the work.

"Lessons in Practical Electricity."

A book thoroughly simplified, treating on the first principles of electricity.

517 pages; 404 illustrations; 102 experiments; 154 worked out problems; 438 review questions.

Price (add 15c postage).....................$2.00

Hydrometer for testing Storage Battery—price...$1.50
Thickness Gauge; see page 699 (fig. 4)—price...$2.50
Compressometer; see page 629 (fig. 4)—price...$6.50
Townsend Grease Gun; see page 622—price...$5.50

Address all orders to A. L. Dyke, Elect. Dept., Granite Bldg., St. Louis, Mo.

"BIG CHIEF" SPARK PLUG

1. **Spark Gap or Intensifier** *non-adjustable*, **built in brass cap. Creates hotter spark at firing point, igniting a leaner mixture of gasoline.**

2. **One piece brass cap and terminal wire spun on porcelain. Cannot come apart.**

3. **Double copper asbestos gaskets** turned over shoulder of porcelain. Cannot leak compression.

4. Flat firing point. Produces blaze instead of faint spark.

THE Spark Intensifier is one of the features of the "BIG CHIEF" Spark Plug. This Intensifier (1) increases the intensity of the spark to such an extent it will fire through carbon or oil and will ignite a lean mixture under high compression.

Other features are embodied in its rigid, indestructible construction and as pointed out in 1, 2, 3 and 4.—See illustration.

AIRPLANES: Different Types. Names of Parts. Control Members and Their Purpose. Instruments. Principle of Flight.

It is not the intention of the writer to deal with this subject in a theoretical manner. Merely the fundamental principles will be treated. See page 933 for Liberty Engine.

Types of Airplanes.

Monoplane is a type of machine using but one pair of wings or planes, or lifting surface, fig. 1, chart 398.

The Biplane is the type using two wings or planes, as shown in the Wright-Martin or Curtiss, chart 399. It is the type used most.

The Triplane is one having three wings or planes, fig. 4, chart 398.

The Seaplane, also called the Hydroplane, and Hydroaeroplane, is the type shown in fig. 3, chart 398.

Tractor type is the type of airplane where propeller (1) is attached to the front, **pulling** the machine through the air—see figs. 1 and 3, chart 399.

Pusher type is where the propeller (1) is back of the wings, or main lifting surface and **pushes** the airplane instead of pulling—see fig. 2, chart 399.

The tractor type is used most, however, in Europe, there are many "pusher" type machines.

Engines used on airplanes are 4, 6, 8 and 12 cylinder. With Gnome type explained in chart 403, the number of cylinders vary from 7 to 14.

A Twin-Engined Airplane refers to a type of airplane using two engines,—as the Curtiss, fig. 1, chart 399, and the Gotha, fig. 2.

Propeller or Aerial Screw.

This is a subject which interests aeronautical designing engineers, therefore will be treated briefly.

The purpose of the propeller is to pull or push the airplane through the air which is termed the **thrust**.

The principle of the propeller on an airplane is similar to the principle of a screw propeller on a motor-boat, but differs in construction.

The speed of the propeller is usually up to 1400 r. p. m. and propeller in most instances is directly connected to crank shaft of engine.

On some machines, the engine speed is higher, therefore the propeller is geared down. For instance, the Sturtevant and Thomas engine speed is 2000 r. p. m. and through a system of gearing, chart 402, the propeller is geared down to 1400 r. p. m.

Twin propellers are where two propellers are driven from one engine by two chains, as on the early Wright machine, as per chart 402.

Propeller slip—when the propeller screws itself forward the air slips past the blades, so that the propeller does not move forward so quickly as if there were no slip. For instance, if a propeller is designed with a pitch of say ten feet, but advances but eight feet, then the slip is equal to 20 per cent.

Pitch—the distance moved forward at every revolution of the propeller, if there were to be no slip, is called the "pitch." The pitch multiplied by the number of revolutions per minute is the distance moved forward per minute. This will be the speed of the machine if there were to be no "slip."

The two-blade propeller is used most and is considered most efficient. **Four blade** propellers are also used, but the two-blade will do the same work. For if a four-blade is used, then the pitch-ratio must be **less**.

N & A

*Two types of two-blade propellers well worth mentioning, are shown in illustrations. One (N), is called the Navy type and the other (A) is called the Army type. The difference between the two is in the curve or camber of blade. The diameter and speed of a propeller has a great deal to do with its efficiency. Therefore the diameter and pitch of a propeller must be designed according to power and speed of engine. Eight and ten foot di. are used extensively, but seldom under six feet.

Thrust means to push or drive with force. Although this is not the technical meaning, we will accept it here.

Control Members.

The rudder is used for steering the airplane to the right or left, called "yawing," or changes direction of motion. It is usually operated by the foot by movement of rudder bar 23, chart 400, which is connected to the rudder (8) by wire cables. Moving rudder to the left causes machine to turn to the left and vice-versa.

The elevators are used primarily for ascending and descending. They are operated by movement of the lever (20), forward and backward. This movement raises or lowers the elevators by connection with lever by wire cables, which causes machine to ascend when elevator is up and descend or "nose-down" when elevator is lowered. This action is caused by the pressure of wind pocketing against the surface of the elevator which causes a "nose-up" position when up, and "nose-down" position when elevator is down.

Banking, refers to lateral motion or tipping of either side. The movement can be controlled by movement of the lever (20), to either side, which moves the **ailerons** (9, fig. 3, chart 399). By dropping the aileron down, on one side, the air pressure strikes it **underneath**, causing that side of wing to **raise** higher than the opposite side. At the same time the aileron is dropped down on one side it is raised on the other side, which by pressure of air on **top**, causes that side to **lower**.

*Compression of engine not as high on Navy type engines as on Army type (see page 934). The Navy type propeller is often a "pusher" type.

Fig. 1—A Monoplane, note absence of lower wing surface.

A "cabane" is the tripod above the wings to which the guy-wire bracings are attached.

Fig. 2—A modern tractor type Biplane. Equipped with Hall-Scott type A5 engine. Note the "cambered" wing and "staggered" struts.

Fig. 3—A modern tractor type Seaplane, also termed a Hydroaeroplane. Hall-Scott equipped engine. Note the floats or boats for running in the water. It is capable of running in the air or water. This machine would also be termed a "biplane."

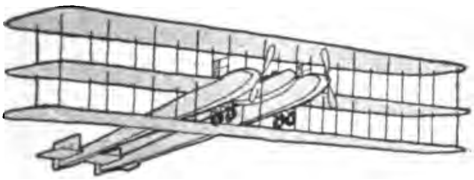

Fig. 4—Triplane—tractor type. Twin-engined.

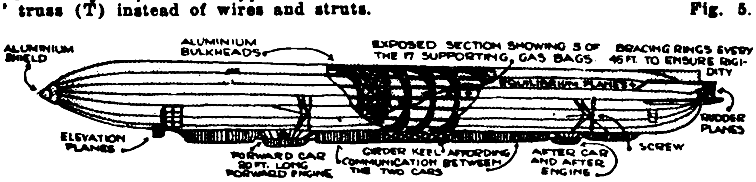
Fig. 5—A biplane, tractor type—with the "Warren" truss (T) instead of wires and struts.

Fig. 5.



Zeppelin Air-Ship.

This type of air-craft would be termed a dirigible, lighter-than-air type—because it is supported in the air by gas.

Engines are located in the forward and aft car swung under the supporting frame-work.

Propellers (screws) are operated by engine. There are four propellers, two on each side mounted above the cars to framework. Power is transmitted through bevel gears. Propellers are three-bladed and 10-ft. di.

Change of altitude is effected by means of two pairs of plane-sets, one forward, other astern; each set made up of four parallel planes, attached laterally, just over the keel.

Gas bags which support the machine in the air are placed as shown, with aluminum bulk-heads between each. Ruberoid is then placed over them and frame-work. If one bag is punctured, others will support craft, by throwing off ballast. The newest Zeppelins are 680 ft. long, 75 ft. di.; 60 m. p. h.

CHART NO. 398—Airplanes; Heavier-Than-Air Aircraft. Dirigible; Lighter-Than-Air Aircraft.

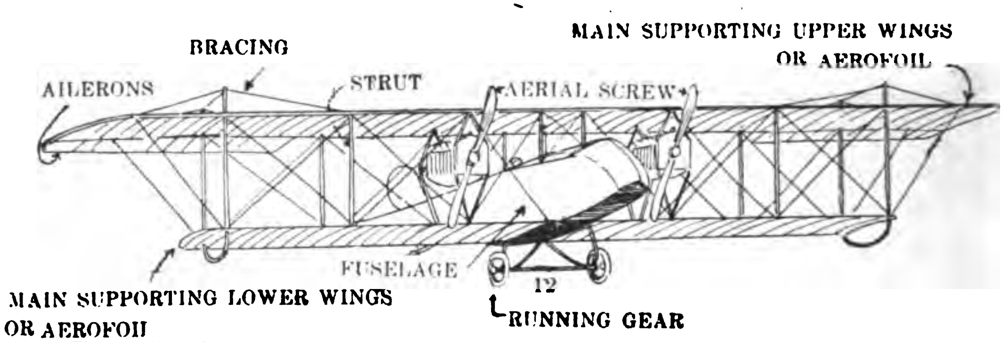


Fig. 1—The Curtiss biplane—tractor type—twin-engined.

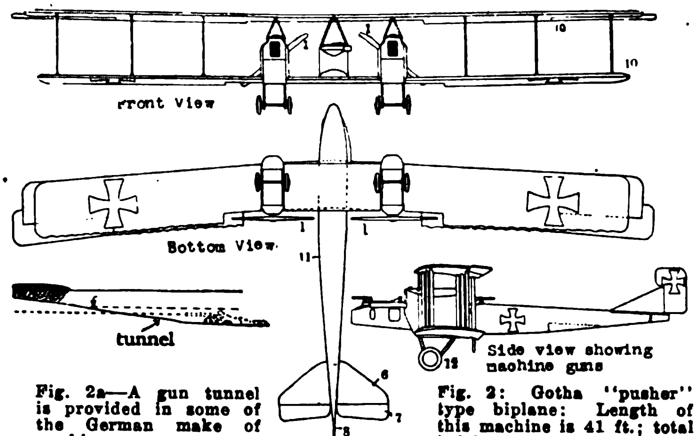

Fig. 2a—A gun tunnel is provided in some of the German make of machines.

Fig. 2: Gotha "pusher" type biplane: Length of this machine is 41 ft.; total height 12 ft. 6 in.; span of upper wings including ailerons 77 ft. 7 in.; span of lower wings 72 ft.; total surface of wings 1000 sq. ft.

Types Of Airplanes.

The illustrations on this page are intended to show the difference between the "tractor" and "pusher" type—also the "twin-engined" airplane.

The Curtiss, fig. 1; there are two propellers, each operated by a separate engine, therefore this would be termed a "twin-engined" biplane. Note the propellers are in front, therefore a "tractor" type.

The Gotha, fig. 2; is a "twin-engined" biplane, but "pusher" type propellers, which are placed in the rear instead of the front.

The Wright-Martin, fig. 3; there is one propeller placed in front, therefore it would be of the "tractor" type biplane.

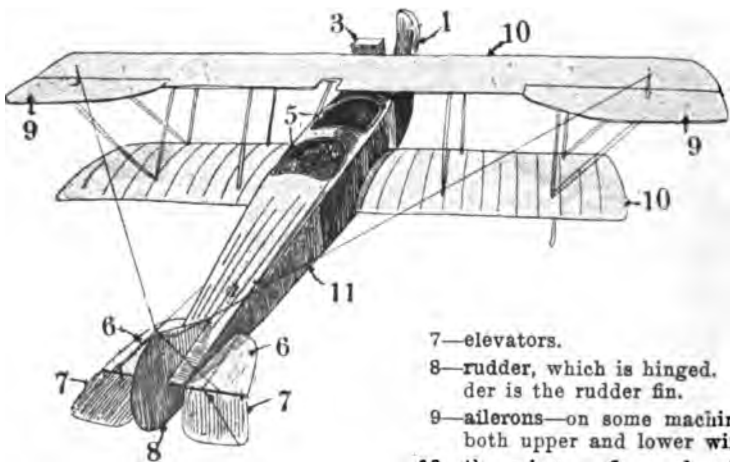

Fig. 3—A biplane—tractor type.

On some types of machines the ailerons (9) are operated simultaneously with rudder. For instance, in turning to the left, right aileron is lowered and rudder turned to the left, tilting or "banking" machine to the left, and vice-versa. It is always necessary to "bank" machine when making a sharp turn.

Parts Of An Airplane.

1—aerial screw or propeller.

3—radiator.

5—cock pits.

6—fixed horizontal stabilizer.

7—elevators.

8—rudder, which is hinged. **Directly behind the rudder is the rudder fin.**

9—ailerons—on some machines **there are ailerons on both upper and lower wings.**

10—the **wing surface, also termed upper and lower plane or aerofoil; the aerofoil, however, indicates the difference between an ordinary surface and one inclined at an angle to the direction of motion, having thickness and cambered or curved.**

11—the **body; the fuselage is the framework separate from the wings.**

12—**chassis** or **landing gear—see fig. 1.**

CHART NO. 399—Airplane; Types and Name of Parts.
(Illustrations from Motor Age and Automobile.)

Lateral motion can also be controlled by **warping or twisting the main lifting surface or wing, which increases or lessens the angle to which the "leading edge" (fig. 9, chart 401), offers to the wing. This warping of the wing is now seldom used, the ailerons having taken the place. Many machines now have ailerons on both upper and lower wings.

Stabilizer (6, fig. 3, chart 399) is for the purpose of preventing airplane from assuming a vertical position—especially when wings at front are at an extreme angle to the wind. In other words, the stabilizer buoys the tail up when flying. See page 907, for further explantion of stabilizers.

Brief Explanation of Ascending and Descending.

When starting a flight, aviator enters cock-pit, fastens safety belt. Engine is started. Airplane then rolls swiftly over the ground and with a run of about 100 yards, skimming the ground, the control (20) is moved towards him. This motion causes elevator surface (7, fig. 3, chart 399) to be tilted upward to line of flight and airplane ascends. The start should be made **against** the wind.

Starting of engine is usually by turning propeller. A number of modern airplanes are equipped with the starting system explained on page 821. When engine stops in mid-air, if not equipped with a starter, the aviator then glides or spirals down. High compression engines can not be started by movement of propeller with air. It is stated that the Gnome will start in this manner.

The ascension can be made in a forward or spiral motion. If a spiral, at reasonable height, then one side is "banked" or tilted by movement of lever (20) to the right or left side. If the turn is to the left, the right aileron is lowered, which causes the air to "pocket" against the aileron surface, creating pressure, therefore the right wing is raised higher, at the same time the rudder is turned to the left. The elevator is raised sufficiently to keep the wing surface at the proper climbing angle.

†**When descending**, engine is throttled down to about 250 or 300 r. p. m. and machine is "nosed-down" by movement of elevator down. Descent is made with a straight forward glide or wide circle or spiral, by movement of aileron or rudder. When within landing distance, the machine is "straightened-out" by movement of elevator. This straightening effect, causes the machine to check its descension by a sudden air pressure under main wings. By skillfully manouvering of elevator, the machine, after skimming over the ground, finally stops with tail-skid striking the ground first. (fig. 8, page 906). The wheels touch the ground last. Engine is then stopped. **Landings are always made against the wind.**

It is difficult for the beginner to judge just where to "straighten-out" preparatory to landing. When he straightens out too soon, this often results in a novice landing "tail-heavy," breaking the tail skids. When he does not straighten-out soon enough, the result is the wheels strike the ground, and this braking effect causes the plane to "nose-over," breaking propeller and bending engine crank shaft—see fig. 30, chart 401.

When engine stops in mid air, the usual procedure is to "glide" or "spiral" or "volplane" to ground, as explained. Landing is just as easy as if engine was running, except one must take chances on condition of ground where he lands.

Gliding is a straight forward down movement just steep enough to assume effective control of the ship with power off. This is also called **volplaning**.

Principle of Flight.

There are two essential factors necessary in order that the airplane, a heavier-than-air machine, rise from the ground. They are **thrust** and **lift**.

There are two factors which offer resistance to the airplane rising from the ground, they are known as **gravity** (resistance downwards) and ***drift** (resistance horizontally, also known as "head-resistance.")

The aerial screw or propeller produces the thrust through the air, which overcomes the resistance or drift. The **lift increases** as the speed of the thrust increases, therefore **gravity is overcome** and result is the wings have a lifting effect, produced as will be explained.

It is well to note that, for an airplane to be supported in the air, it is essential that it be kept in motion through the air and not by the motion of the air past the airplane stationary. In other words, the mass of air engaged, the velocity and force the wing surfaces engage the air, is the theory advanced for the support of the plane in the air.

How this lifting effect is brought about, is explained as follows:

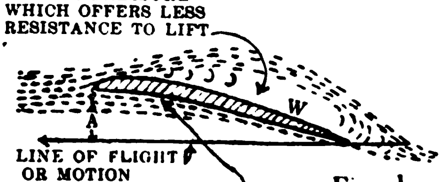

Fig. 1

Supporting and lifting effect under wing: The wing surface is (W). The horizontal line we will call the direction of "line-of-flight-or-motion." The dotted lines represent the wind or air current, and at another point, say one-third of the way back from front or leading edge of wing tip, is the "center-of-pressure" or (C. P.—which varies, as will be explained later). As the bottom of the wing meets the air, it results in

†The purpose of running engine slowly was to have power to ascend again if the landing was not favorable. The machine will slightly nose-down when power of propeller or thrust is off. If nosed-down too much descent will be too rapid. **Warping of wing tips is a similar action as lowering the aileron and for same purpose, see chart 402.

*Drift also refers to resistance offered by the shape of wings, struts, etc., or any other factors which would have a tendency to oppose lift.

*A spiral is made when space is limited in landing. A glide usually carries one a great distance.

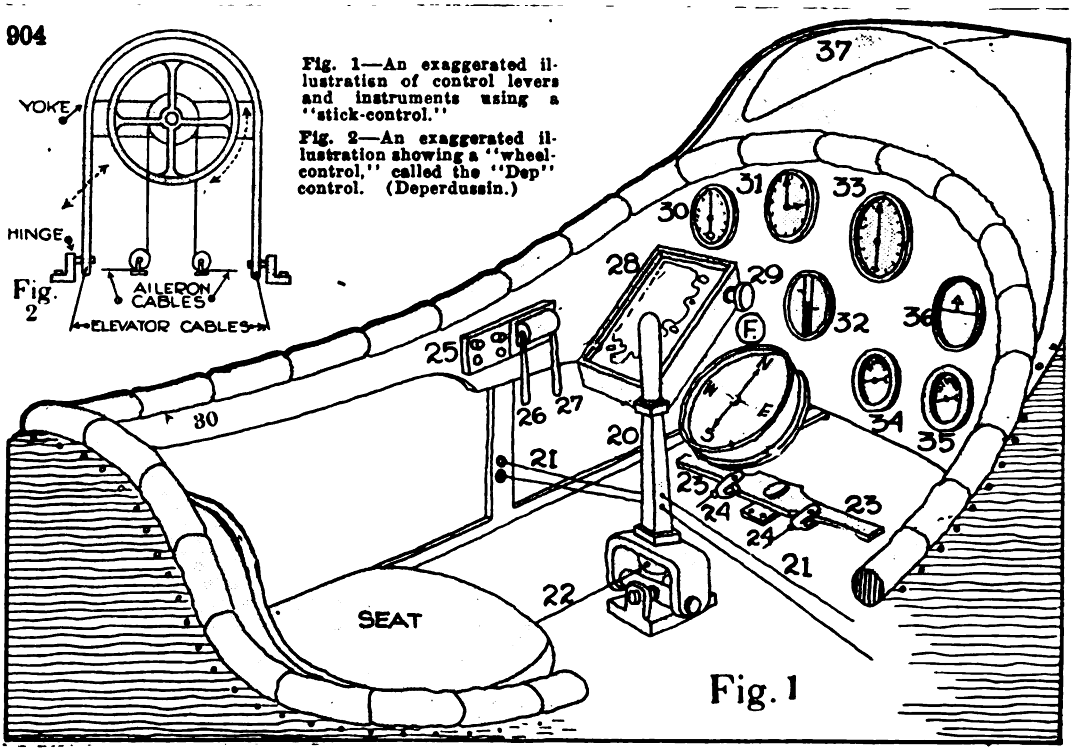

Fig. 1—An exaggerated illustration of control levers and instruments using a "stick-control."

Fig. 2—An exaggerated illustration showing a "wheel-control," called the "Dep" control. (Deperdussin.)

Name and Purpose of Control Levers and Instruments.

20—Control stick (on many machines a wheel control is used as per fig. 2). This lever controls the movement of ailerons (9, chart 399) by moving to either side. By moving forward and back it operates the elevators (7, chart 399).

21—Aileron cable or wires; 22—Elevator cable or wires; 23—Rudder foot control; 24—Rudder cables; 25—Ignition or magneto switches; 26—Carburetor throttle lever; 27—Ignition advance lever; 28—Map holder; 29—Thumb nut for rolling map.

30—Tachometer, similar to a speedometer. Indicates number of revolutions of engine crank shaft, connected by flexible shaft; **31—Clock.**

32—Temperature thermometer, or indicator, is for the same purpose as the "motor-meter," explained on page 188. This instrument, however, instead of being placed in the top of the radiator cap, is placed in view of the aviator by connection of an extension pipe. It is also often installed directly in the water pipe, coming from the cylinder nearest the propeller. Due to the fact that if water becomes low in radiator, it does not operate properly—hence reason for placing it in the water pipe.

33—Altimeter, which indicates the height. The barometer of the aneroid type is also used for this purpose which indicates the height by indicating the density of the air. The higher the altitude, lighter the air and less the gravity.

34—Oil pressure gauge, indicates oil pressure of engine oiling system.

35—Gasoline gauge, indicates pressure of air in gasoline tank. The pressure fuel system is in general use, per page 854 (see also page 909).

36—Banking indicator, stands at zero or center when a machine is on a level—when wings bank or tip to the side, the needle moves accordingly from either side of zero. This instrument is also termed an Inclinometer.

The Inclinometer, in other words, indicates angles, and is nothing more than an arched spirit level. One is mounted to show angle at sides or lateral stability (side tips), and another could be mounted to show the horizontal stability or "nose-down" or "tail-down" position (the air speed indicator is also suitable for this).

37—Wind shield; F—Compass, indicates direction.

Air speed indicator, a type called the "**Foxboro**," (not illustrated) consists of a very strong and accurate low-range indicating differential pressure gauge. Indicates the air pressure. For instance, a nose-down direction will show an increase of air pressure and a tail-down a decrease. Therefore, in a way, it serves as an inclinometer.

The instrument is located at any current point to be observed by the pilot, and is connected to a Pitot tube or nozzle by means of smooth copper tubing.

The scale on the indicating part of instrument is calibrated to read in the unit of miles per hour, this being the relative wind or force, acting against the planes of the machine and holding it in the state of buoyancy.

The nozzle is especially calibrated for use with these instruments, and is usually located on one of the forward midwing struts with the nozzle pointing in the direction of motion, so made that water or moisture cannot enter. (see page 800 for principle of Pitot tube.)

The throttle lever is used to govern speed during flight. **The spark lever** is retarded when starting engine on the ground and advanced after engine is started and then advanced and left in this position.

There are usually two magnetos for engine, a separate switch is provided for each ignition unit.

Control movements: To ascend, pull lever (20) back, this places elevator up. **To descend**, move (20) forward, places elevator down position. **To balance machine if inclined to right**, move (20) to the left side, this lowers right aileron, which causes right wing to raise. **To balance, if inclined to left**, move (20) to right side, this lowers left aileron, causing left wing to raise. **To turn to right, first** "bank" or tilt machine to the right, by moving (20) to the right side, lowering aileron on left, raising left wing, then move rudder to right by movement of rudder bar (23), right side. **To turn to the left**, "bank" to the left and rudder to the left. **Neutral position**; elevators are level position also ailerons and 23 and 20 in vertical position.

CHART NO. 400—Control Levers and Instruments. See also page 921.

At high altitudes the air is lighter or less dense, therefore lack of air causes a decrease of about ten per cent of engine power at and above 6000 feet. Carburetors are designed with air openings which can be opened wider at high altitudes in order to increase air supply to carburetor.

the air striking the under part of wing, when it is compressed, causing it to **push up against the under surface of the wing and is gradually diverged downward, thereby giving the wing its supporting effect.

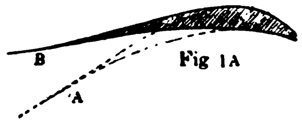

Fig 1A

This is further demonstrated by the wings of a gull (fig. 1A). We will assume that the gull is making a flight in a horizontal direction as per "line-of-flight" (fig. 1). The wings would assume a horizontal lifting position as shown, (B).

Lifting effect above wing. Over the upper surface of the wing the opposite action is taking place.

Instead of pressure above the wing, a **partial vacuum** is created by the air striking the forward edge of the wing and being deflected upwards and over a greater part of the wing surface as shown in fig. 1. In other words, meaning that there is very **slight** air pressure above. The result is that if the pressure below the wing is greater than above it, and a partial vacuum is created above the wing, the mass of air engaged under the wing by motion produced by the thrust of the propeller, will cause the wing to have a **lifting** effect. This is the fundamental principle of flight.

To demonstrate the theory that a partial vacuum is created above the upper surface

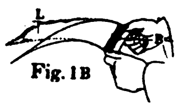

Fig. 1B

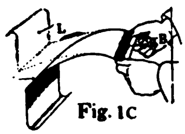

Fig. 1C

of a curved wing; take a sheet of paper and hold it as shown in illustration fig. 1B. If you blow horizontally on the edge at B, along the upper face, the rear of the paper will rise (L). Blowing along the under surface will be found to have a much less steady effect in lifting the rear end.

If we now hinge the rear (fig. 1C), at about ¼ of its length and curve it down, blowing along the upper surface of the sheet, the rear hinged portion will lift almost vertically in the air and right in the face of the wind, whereas if the hinged portion be kept flat it will not lift, and if rear end is curved upward it will only vibrate and act as a drag to the lifting effect of the sheet or plane forward of the hinge.

This brings out the fact that a curved plane is necessary and the hinged portion explains how the ailerons give a lifting effect to that side of the plane when lowered.

There are a number of factors that must be considered in order to obtain the best lifting effect. Two particularly, are the curve or "camber" of the wing and the "angle" it is placed in **relation** to the "line-of-motion" or flight, as will be explained.

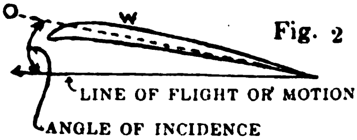

Fig. 2

Angle-of-incidence; W, is the wing; O, is the center line of wing from which we will base our angle. The line-of-flight or motion is shown below it.

The angle between this line (O) and the line-of-motion is termed the "angle of incidence" and right here, together with the curve or camber of the wing, is what governs the lifting capabilities of an airplane, of course assuming that the thrust is equal.

Camber of the wing, or the curve, is necessary on top as well as on the bottom. The camber varies with the angle-of-incidence. The greater the velocity, the less "camber" and "angle-of-incidence."

For great lifting at steep incline or angle, the wing with a greater curve or camber is designed. But, when a wing is designed for great lift, speed is sacrificed.

For great speed, the wings are not cambered or curved as much. When designed for speed, then extreme lift per square foot of surface is sacrificed.

Airplanes designed for high speed cannot land at slow speed.

Airplanes designed for landing slow and safe and getting off the ground quickly, then sacrifice high speed.

When airplanes are slow speed they are likely to encounter "air-pockets"—meaning that if a gust of wind traveling at a greater *speed increase than the flying range of the airplane, should strike the airplane from the rear when flying, the result would be that the plane would drop, due to the air support being taken out from under the wings. To overcome this, the aviator "noses-down" until greater speed is obtained when he "straightens-out" again and assumes his climbing angle.

The aim of designers therefore, is to produce a machine which will get off the ground quickly, lift, have maximum speed and land at a safe speed.

The lift decreases at higher altitudes, due to the fact that the air is lighter or less dense, which affects the operation of engine. **There is also a limit to the climbing altitude** of a machine, for instance, it will be seen that the higher speed the plane is put to, the greater will be the pressure below the wing and also the vacuum above, so that after the vertical pressure on the wing equals the weight of the machine, any further pressure on account of higher speed would tend to flatten out the angle at which the wing is flying, reducing the angle, bringing it more to a straight line, causing the airplane to travel in a horizontal line instead of lifting it upwards.

**The air must meet the wing surface at such an angle that a downward velocity be given to it after the plane has passed over it. The actual velocity required will depend upon the weight to be carried and the supporting surface that is used.

*It is rare that a wind gust appears with over a 20 miles an hour increase in air speed, so that if any plane today has a speed range of 20 miles per hour—say from 40 to 60 or 50 to 80—this plane is practically free from the effect of this type of "air pocket." (from "Acquiring Wings"—see foot note page 907.)

Empennage.

The empennage is the tail assembly.

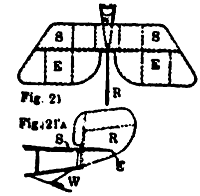

Fig. 21—Top view of rear control members: S—stabilizers; E — elevators which are hinged and operated from seat by control (20, chart 400); R — vertical rudder, operated by rudder foot bar (28).

Fig. 21A—Side view of above. The tail-skid (W) is a form of shock-absorber, which prevents damage to rear when landing.

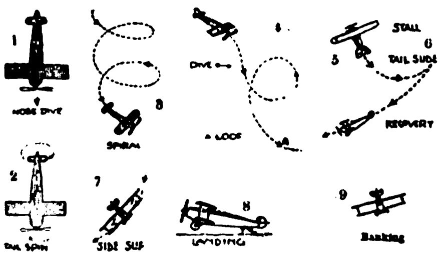
*Flying Terms.

A nose-dive (1); occurs when a descent is made at too great a speed and too steep an angle, so that supporting pressure is lost. Considerable rudder and elevator action is necessary to place machine horizontally again.

Tail spin (2); machine in vertical position, tail-up and being turned in a spiral, due to several causes. One cause, is due to failure of rudder or elevator to operate, after making a "nose-dive," causing machine to be forced into a small spiral—a very bad and dangerous predicament.

Spiral (3); to descend or ascend in a spiral or wide circle.

A loop (4); speed is gained by a steep dive, then with movement of elevator the loop is made with power on. After looping, elevator is used to straighten out.



Stall (5); when trying to climb at too steep an angle, new pilots sometimes allow their machines to slow down below their supporting speed, when they "stall" and drop tail-first or "tail-slide" as shown. This used to be a dangerous happening, but if sufficiently high in the air, modern stable type machines will recover as shown in dotted lines (recovery).

Side-slip (7); caused generally by taking a turn with insufficient banking, which causes the wings to lose their sustaining effort, once forward motion is stopped. Fliers who know how can now slip for hundreds of feet and right themselves safely (see page 907).

Banking (9); means that the machine is tilted to right or left side. Necessary in turning. Too great an angle will cause a slide-slip (7). See page 960 for method of banking.

Landing.

The proper method to land is per (8) above, and per page 908—tail first.

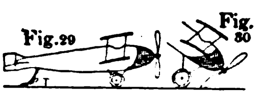


Fig. 29—When landing, "tail-heavy," the tail skids (T) are broken.

Fig. 30—When landing "nose-heavy," due to not straightening out soon enough (see page 908), the propeller is broken and crank-shaft bent. These are common occurrences in training schools.

Dihedral and Aspect-Ratio.

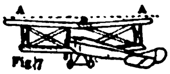

Fig. 7—The Dihedral angle of an airplane is the upward tilt given to the wings, or the angle they are to each other as shown at A. Note (B) in center is lower. The purpose is to assist lateral stability. Quite often it is possible to tell the make of machine in the air by its "Dihedral," as this varies on different makes.

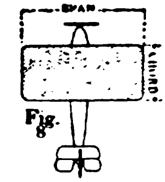

Fig 8—A low-aspect-ratio airplane. Note the "chord" or width of wing is broad and "spread or span" is short.

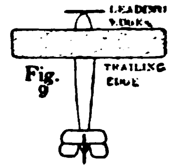

Fig. 9—A high-aspect ratio airplane. Note the "chord" is narrow and the "span" is long. The spread or span divided by the chord gives the aspect-ratio. The same area surface is in each. Large slow machines usually have high-aspect-ratio and speed-scouts, low aspect. See page 907. The high aspect is most efficient.

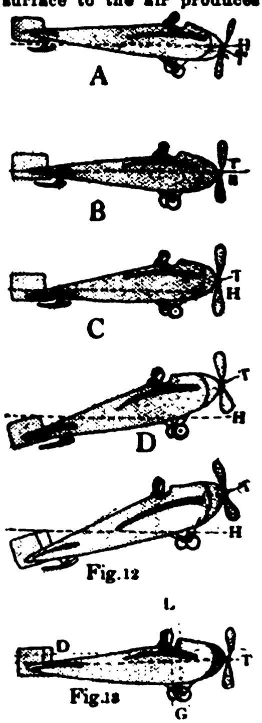
Leading edge, is the front part of wing; **trailing edge**, rear.

Horizontal and Climbing Angle.



A—Horizontal flight; the propeller thrust (T) is slightly below the horizontal line (H). Although this would appear to be descending, the thrust of propeller, when wings are at a low angle, would have a tendency to keep machine in a horizontal position. This gives greater speed when flying at low altitudes in a horizontal direction.

B—Low angle of climb; the propeller thrust (T) is now horizontal, also line (H). This gives a slight increase of angle to wings, therefore there would be a slight angle of climb at low altitudes. The speed is less however, as the increase of angle of wing surface to the air produces greater lift but less speed.

C—Climbing angle; the propeller thrust (T) is now slightly above the horizontal line (H); which gives a slightly greater angle to the wings. This is considered the best climbing angle. The speed however is less than in (B), as the resistance is greater.

D—Extreme climbing angle; the propeller thrust (T) is now considerably above the horizontal line (H). The angle of wings is increased still more—result is greater lift or angle of climb, but resistance is still greater, therefore speed is less than in horizontal climb and B & C climb.

Fig. 12—Excessive climbing angle; the wings are now placed at a still greater angle. The center of pressure (CP) works to the rear of the wing, giving a tendency to oppose the thrust by the wind pocketing at the rear and trying to raise rear of curved wing which causes great resistance therefore considerably less speed and the machine instead of climbing will move horizontally (or stall, page 907).

If the angle is increased to a greater extent the center-of-pressure will work out from under rear of wing, as explained on page 905, and result will be a drop.

Note; illustrations are exaggerated in order to more clearly explain the ill effect of climbing at too great an angle.

Fig. 13—The thrust line (T) is the line running from rear, through center of propeller. The lift line (L) is the line slightly back of the gravity line (G). The gravity line is or should always be slightly forward of the lift line, due to the fact that the machine should be "nose-heavy" and not "tail-heavy" when gliding, with power off. When power is on the thrust overcomes this tendency of nose-heavy. In other words if the power is off it is important that the machine descend "nose-down" instead of "tail-down." The drift line (D) is above thrust line.

CHART NO. 401—Miscellaneous Airplane Information.

*Several of these illustrations from Acquiring Wings—see foot note page 907. See page 93 for explanation of degrees.

When climbing, there is a minimum and a maximum angle. The minimum angle gives the greater velocity and maximum less velocity. Too great an angle would cause machine to fall—because the center of pressure would be changed as explained in the next paragraph.

Center of pressure is continually changing. For instance, when the "angle-of-incidence" is about 7 degrees between, the line (O) and line of motion (fig. 2); as this angle is increased, the center of pressure moves toward the **rear**, therefore, if angle is too great, the center of pressure would move from point where it would properly support the wing surface and result would be a fall.

Fig. 4

Fig. 6

Fig. 4 A stabilizer wing is usually slightly curved at both ends.

Fig. 6. A wing for the control surfaces, are usually double convex type.

Purpose of stabilizers; if center of pressure moves **forward**, the rear of machine has a tendency to drop, tail-down, therefore stabilizers (6, fig. 3, chart 399) are provided to assist in stabilizing or balancing the rear, also prevents pitching forward. This is known as "longitudinal stability." Stabilizer wing surfaces—see fig. 4.

Lateral stability is necessary to prevent side tipping. This lateral balance is usually maintained by "warping" the wings or movement of the ailerons, the latter method being used mostly. On monoplanes the warping method is used extensively.

Directional stability applies to an airplane being thrown out of its course of travel, for instance, by a sudden heavy gust of wind. When turning sharply, it is necessary to make a steep "bank" (tilting sidewise). If this banking is extreme, then the plane "side-slips" or falls (page 906). This is overcome by operating the controls and "nosing-down" until speed is gained then "straightening-out."

GLOSSARY.

AERDROME—a field or grounds used for flying purposes.

AEROFOIL—a cambered, or curved wing, or the lifting surface—but curved.

AERONAUT—one who follows the profession of flying.

AEROPLANE—a machine used for flying, which is power driven and heavier than air.

AILERON—a wing of smaller size placed usually as shown in fig. 3, chart 399. Produces a side or lateral tilt.

AIRPLANE—same as aeroplane.

AIR-RESISTANCE—the resistance offered to the thrust of the machine—approximately four times as much power is required if it is desired to double the speed.

AIRSHIP—a balloon type, lighter than air.

ANGLE OF INCIDENCE—the angle that the line (O), page 905, fig. 2, makes with the line of motion or flight.

ASPECT RATIO—if a wing is six times as long as it is deep, having a spread or span equal to six times the chord, it has an aspect-ratio of six, which is about the average for training biplanes. Anything much above this would be called a high-aspect ratio, whereas wings three times as long as they are deep, would be said to have a low aspect-ratio. See figs. 8 and 9, page 906.

AERIAL SCREW—the propeller.

BANKING—a term applied to the side tipping of an airplane when turning.

BAROGRAPH—records the altitude reached.

BAROMETER—the aneroid type indicates the altitude by density of the air.

CAMBER—a curved surface usually applied to the curve of the wing or propeller.

CENTER OF GRAVITY—a vertical center line which would be termed the weight center.

CENTER OF PRESSURE—a point under wing, from front edge where pressure is centered to greatest compression or balance.

CENTER OF THRUST—a line running from center of aerial screw to rear, fig. 13, page 906.

CHORD—the width of the wing.

DENSITY—compactness; mass of matter per unit of volume.

DRIFT—this word and resistance are analogous, applies to the resistance offered to a machine when moving forward.

DIHEDRAL—see fig. 7, chart 401.

ELEVATOR—a small wing (see fig. 3, chart 399), for ascending or descending.

FORCED LANDING—a landing necessitated by reason of impaired engine.

FUSELAGE—the framework of an airplane, see fig. 3, chart 399.

GRAVITY—the force which draws a body to the earth. The higher the altitude, less the gravity.

GLIDING—a term used when descending with power of engine off.

GYROSCOPE—to give steadiness to flying machines. Intended to keep machine in upright position.

HANGAR—similar purpose as a garage. A place or shed for airplane.

LATERAL STABILITY—the stability of an airplane. To oppose lateral or side tipping.

LONGITUDINAL STABILITY—the stability of an airplane. To oppose tipping forward or backward.

LIFT—the lifting and supporting effect of the airplane wing.

MONOPLANE—an airplane with one pair of wings. The monoplane usually has great speed as the resistance to the wind is less.

PITCH—the distance the aerial screw or propeller advances when completing a revolution.

PLANE—a level surface. Usually applied to the wings of an airplane, but which are usually curved or cambered.

RUDDER—a vertical surface used for turning—see fig. 3, chart 399.

RUNNING GEAR—the wheels and its parts by which the airplane lands and runs along the ground.

SHIP—the airplane.

SIDE SLIP—see page 906.

SPIN—when through loss of flying speed ship drops nose first with a rotary motion.

STALL—a ship stalls when it loses flying speed.

STABILIZER—see page 908 and above.

SKID—a support usually placed at rear of aeroplane to absorb the shock when landing, see fig. 21A, chart 401.

SKIDDING—a term used when an airplane goes to the side further than intended when turning. Also applies to landing.

TAIL-SLIDE—see page 906.

TAIL SPIN—see chart 401.

TAKE OFF—maneuvering after leaving ground under its own power.

TAXYING—maneuver of ship on the ground under its own power.

THRUST—applies to the aerial screw or propeller to push or drive forward.

TRAILING EDGE—see fig. 9, chart 401.

VOLPLANE—see gliding.

WIND TUNNEL—a tunnel used for experimental purposes for airplanes, employing artificial air at various pressures.

Structural Parts.

Structural parts, outside of the engine or propelling machinery, consists of three parts as follows:

(1) the **fuselage** or frame work or body; (2) the **control members**, as rudder, elevator etc., (3) the **wings**.

The fuselage is usually made of light wood (spruce) material and braced with wire and then covered with sheet aluminum or fabric. The control members are shown in charts 404, 401.

Wing Construction.

The wings are made as follows: (A) is the main or end wing rib, fig. 25, which it will be noted is curved or cambered; other inside ribs are shown; B and B1, are front and rear.

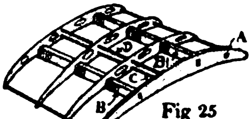


Fig 25

Spars; C and D are thin braces running through the ribs; at the front or "leading-edge," the material is wood or metal; the rear or "trailing-edge" is small steel tubing and sometimes wire.

The covering material of wing completely covers wing, above and below by being sewed and then varnished with a special varnish or "dope" to make material water-proof. The material used in most instances is linen, unbleached. Rubber proofed cloths of all kinds have been tried.

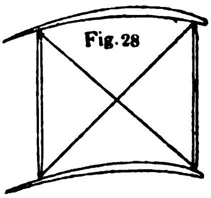

Fig. 28

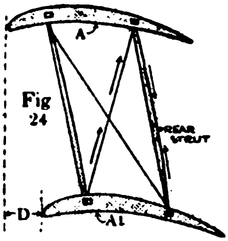

Fig 24

The struts are the up-rights (figs. 28 and 24). They are made of various material. Spruce is used extensively which comes from California. They are cut in half-lengths, center scooped out to lighten them and glued together. Bamboo was formerly used and steel tubes are sometimes used.

The staggered strut is one placed at an angle, between main side ribs A and A1, as shown in fig. 24. This places the upper wing in advance of the lower wing as shown at (D), which is termed "stagger."

The gap is the distance between the upper and lower wing. On a "staggered" type, it can be less than when struts are vertical as shown in fig. 28.

Overhanging is a term used, when the upper wing is longer than the lower wing and projects over lower wing at each side.

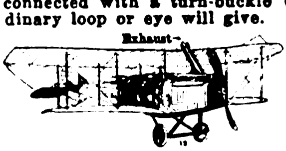
Bracing Wires.

Bracing wires, or as we would term it, guy-wires, are necessary. There are usually cross wires in between the ribs and spars which are covered over and cannot be seen. They assist in supporting the wing frame. **The wires at end, per fig. 24, are "incidence wires."** The lift on the upper wing causes a tension as shown in arrows. The lift or push under lower wing causes a pressure against rear strut—fig. 24. **Drift wires**, fig. 27, take the resistance of the forward motion, the wires opposite are simply reinforcements, sometimes called **landing-wires**.

Fig. 27

The wire, generally used is silver plated piano wire of No. 26 or 28 size. Although stiff, it is **not tempered**. The method of fastening wire is important. **Fig. 26**, shows the end of wire (W) looped and fastened in a special fastening (E), which is connected with a turn-buckle (T), for tightening. An ordinary loop or eye will give.

Fig. 26



The exhaust outlet of an airplane engine is usually arranged as shown at E.

A Geared-Down Propeller.

A geared-down propeller is used (fig. 15) where engine speed is higher than desired for propeller.

Note the **direct-drive** propeller, chart 407.

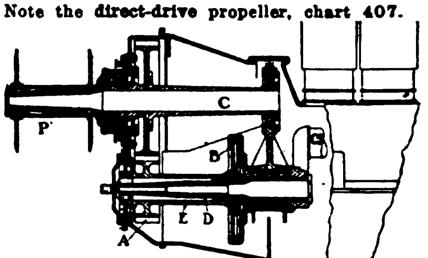


Fig. 15

P—is propeller hub; C—propeller shaft; CS—crank shaft; D—crank shaft extension; E—connects through disc (B) driving gear A, thence gear above it which is connected to propeller shaft.

Early Model Wright Biplane.

As a matter of information the illustrations are shown of this early machine. The elevator planes (V) are placed in front of machine. The one engine (M) drives two propellers (H).

Instead of ailerons the upper wing tips (fig. 23) and lower wing tips (fig. 24 below) are "warped." or flexed. This is a similar action to lowering and raising the ailerons as on other machines.

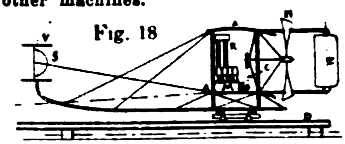

Fig. 18

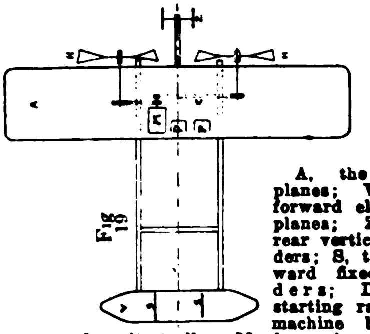

Fig. 18

A, the main planes; V, the forward elevation planes; Z, the rear vertical rudders; S, the forward fixed rudders; D, the starting rail, the machine being mounted on its trolley; M, the engine; C, the driving chains; H, the propellers; P, the seats for driver and passenger; R—radiator.

For instance, turning to the left; (1) rudder is brought to left; (2) aeroplane then makes turn and its outer tip or wing rises; (3) wings are flexed so that inner tip of wing is depressed (in other words the **warping of the wing** causes the angle of incidence to increase) and rudder is put over to right; (4) inner tip then lifts and tries to slow down, but as the rudder opposes this tendency, the machine is kept on its course.

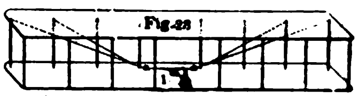

Fig. 23

Fig. 24

Fig. 23—Method of "warping" the wing tips on the early Wright biplane.

Fig. 24—Method for "warping" lower wing tips.

There are a score or more airplane engines. To deal with all would require a book in itself, therefore only typical examples will be shown.

Types of Engines.

We will classify airplane engines as "fixed type" and "revolving cylinder type."

The fixed type is where engine cylinders are stationary and are made in 4 and 6 cylinder vertical and 8 and 12 cylinder "V" type. This is the type in general use and is similar in principle to the automobile engine, especially of the racing type, which is designed for running at maximum speed for long periods of time.

The 8 and 12 cylinder "V" engines are very popular, due to the low weight per horse-power. The flywheel is practically eliminated, as the propeller takes its place.

The revolving cylinder or "rotary-cylinder" type is the Gnome, (chart 403), a French invention. This style of engine was used extensively in small, high speed, single seated machines. Another is the La Rhone.

A German machine used an engine of this type, called the Fokker, but it was copied from the French. Roland Garros was the father of it. He used a Morane-Saulenier, a small, fast, single-seater of French design, using the Gnome engine. Garros contributed to its development of adding the method of synchronizing the time of gun shot with time of propeller, in other words, so that he could shoot directly ahead yet not damage the propeller. This machine was captured by the Germans and improved and renamed the Fokker. These machines were soon discarded in favor of Biplanes. The rotary engine has also given way to the fixed engine of the automobile style with a multiple of cylinders, lighter and more powerful.

***Airplane Engine Ignition.**

Ignition is usually by magneto. Two separate systems are usually provided, each having separate wiring and plugs.

For instance, on the Wisconsin 6 cylinder engine, chart 405, there are two 6 cylinder magnetos. Both operate at the same time, and both are connected to the same spark advance lever. Should one fail, the other will still operate engine, but with slight loss in power.

On the Wisconsin 12 cylinder engine, there are four 6 cylinder magnetos, two for each set of six cylinders. See chart 404, fig. 3, (M1-M2). On twelve cylinder engines—two 12 cylinder magnetos could and are used on some of the other makes of engines. See pages 290 to 292 and Insert for "Dixie" magneto.

On the Hall-Scott 6 cylinder engine, two 6 cylinder magnetos are used and driven as shown in chart 407.

On the Sturtevant 8 cylinder engine, chart 405, there are two 8 cylinder magnetos. Therefore it will be noted that double ignition is provided.

Spark Plugs.

There are usually, two spark plugs per cylinder and due to the fact that nearly all airplane engines have overhead valves, the plugs are placed in the side of the cylinder.

Spark plugs for airplane engine use must be of substantial construction in order that they stand the high compression—page 238.

Engine Starter.

The starting of engine by turning propeller by hand was the method formerly used, but self starters are now being placed on a great number of machines. The Christensen "gasoline and air" method, explained on page 321 being a popular system.

Fuel and Fuel System.

Fuel used, is gasoline. The Hall-Scott Co. recommend gasoline as follews; gravity 58-62 deg., Baume A. Initial boiling point (Richmond method) 102 deg. Fahr., sulphur .014. Calorimetric bomb test 20610 B. T. U. per lb. This latter part may read like Greek to the average student, but it means that the gasoline must be of a test which will produce a certain heat. For instance, a piston 10 sq. in. head surface and operating at a speed of 2000 ft. per minute would burn approximately 0.146 lb. of gasoline per minute. As one pound of gasoline contains about 19,000 British Thermal Units (the unit of heat—B. T. U.) the total heat generated per minute in the cylinder would be 2,774 B. T. U.'s at sea level.

This will give a fair idea of the thermal (heat) conditions of an engine used for airplane work operating continuously under full load. Therefore the Calometric test is a test for measuring the heat produced—which is an important factor in airplane engines. (see page 861, meaning of B. T. U.)

The fuel system used on most airplanes is the principle described on page 854, used on the Packard, by which the gasoline is forced to the carburetor by air pressure, but instead of being forced to carburetor, the gasoline tank is hung low and gasoline is fed by pressure to a small tank under upper plane, which feeds the carburetor.

Lubrication.

The force feed system is the adopted and standard method, an example of same is given on page 915. Note method of *cooling the oil.

****Compression.**

The compression of airplane engines is somewhat greater than on automobile engines. As a rule the explosion pressure is four times the absolute compression pressure based on the assumption that the cylinder is filled with charge to atmospheric pressure at the beginning of the compression stroke.

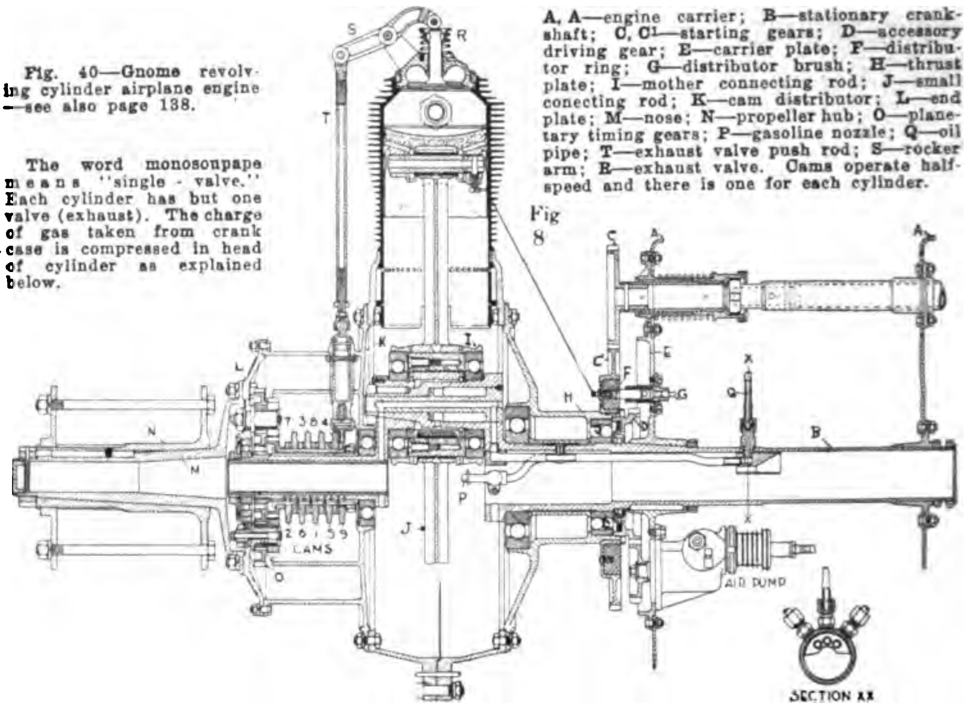
The water cooled engine with multiple of cylinders developing large horse-power with cylinders made of aluminum with steel or cast iron liners and those with steel cylinders with welded steel jackets are proving to be the successful types of airplane engines. *See also page 293—Dixie magneto.

*The reason for cooling the oil is due to the fact that an airplane engine usually runs at full power for long periods of time and considerable heat it generated. When petroleum oils are treated with air and oxygen at temperatures above 800° F., water and carbon dioxide are readily formed. The oil also loses its heavy lubricating film, so very necessary between bearing surfaces, and thins down to a point where the lubricating film is lost. Hence advantages of keeping oil at a low temperature.

**The compression on a motorcycle engine, per Insert No. 3, as a general rule is also rather high where speed is desired, but on the U. S. A. motorcycle engine, the compression is slightly lower than the average. This somewhat depresses the power curve, but engine will run better on wide open throttle at lower speed, enabling machine to "hang-on" with great tenacity and pull with power through sand, mud, etc. The U. S. A. motorcycle engine is similar to engine shown on Insert No. 3, with overhead inlet valves at 45 degrees. See also pages 793, 817, 629, 626, 640 on compression.

Fig. 40—Gnome revolving cylinder airplane engine —see also page 138.

The word monosoupape means "single - valve." Each cylinder has but one valve (exhaust). The charge of gas taken from crank case is compressed in head of cylinder as explained below.



A, A—engine carrier; B—stationary crankshaft; C, C1—starting gears; D—accessory driving gear; E—carrier plate; F—distributor ring; G—distributor brush; H—thrust plate; I—mother connecting rod; J—small conecting rod; K—cam distributor; L—end plate; M—nose; N—propeller hub; O—planetary timing gears; P—gasoline nozzle; Q—oil pipe; T—exhaust valve push rod; S—rocker arm; R—exhaust valve. Cams operate half-speed and there is one for each cylinder.

A—air pressure pipe; B—fuel pipe; N—revolving cylinders; D—pulsation gauge for oil feed; E—fuel control valve; F—fuel tube to crank case; G—air pressure gauge; H—hand air pump; J—starting handle; P—aerial screw or propeller. Castor oil used to a great extent for lubrication.

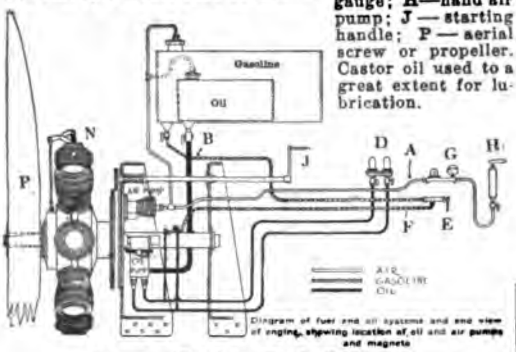


Diagram of fuel and oil systems and end view of engine, showing location of oil and air pumps and magneto

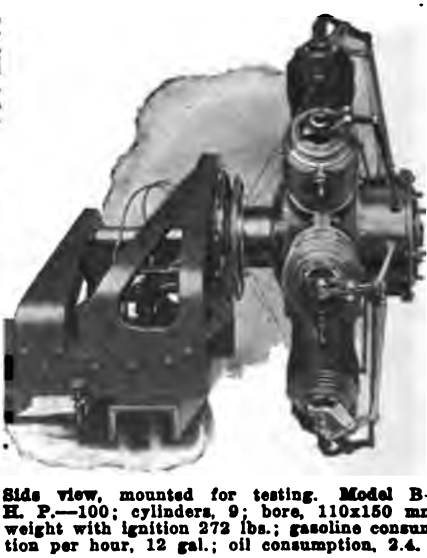
Gnome Engine Fuel System.

Fuel system. Gasoline is fed to crank case through a shut-off valve (E), through tube (F), through hollow crank shaft to a spray nozzle located in crank case. There is no throttle valve or carburetor. The gasoline in gasoline tank is under 5 lbs. pressure per sq. in. by air pump. When cylinders are within 20° of end of inlet half—revolution, a series of small inlet ports all round the circumference of wall is uncovered by top edge of the piston whereby the combustion chamber is placed in communication with the crank chamber. The crank chamber is at atmospheric pressure and combustion chamber is below atmospheric, result is, a suction is created which draws gas from the crank chamber to combustion chamber. The air for mixture is provided by admission through exhaust valve during first part of the inlet stroke. Originally an inlet valve was located in center of piston head—this is not now used.



Side view, mounted for testing. Model B-2; H. P.—100; cylinders, 9; bore, 110x150 mm.; weight with ignition 272 lbs.; gasoline consumption per hour, 12 gal.; oil consumption, 2.4.

Gnome Ignition.

One high tension Splitdorf magneto is provided, located in the thrust plate in an inverted position and driven at a speed to produce 9 sparks (9 cyl. engine), for every two revolutions—that is, at 2¼ times engine speed. A distributor is shown in top illustration, mounted separate at (F & G).

—continued on next page.

CHART NO. 403—The Gnome Monosoupape Revolving Cylinder Engine—made by The General Vehicle Co., Long Island City, N. Y.

(From Automobile and Automotive Industries and Motor Age.)

Gnome Ignition—continued.

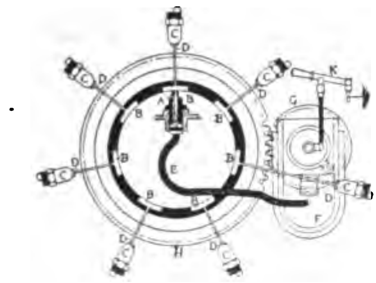


Fig. 10—Wiring of ignition system used on Gnome engine

In the Gnome seven-cylinder engine there are three and a half explosions per revolution, or seven every two revolutions. The firing order is 1-3-5-7-2-4-6.

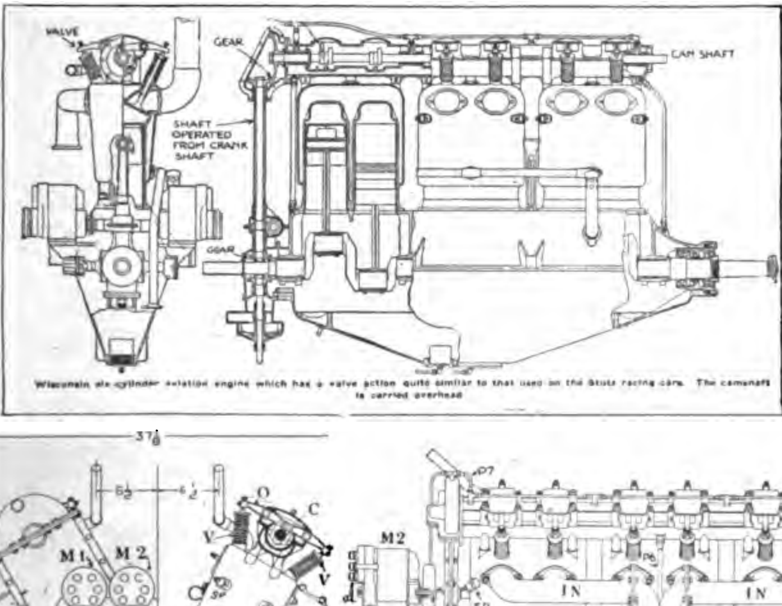
In the fourteen-cylinder engine the firing order is the same, with one set of cylinders alternating with the other and giving twice as many explosions per revolution.

The wiring of the ignition system is shown in fig. 10. It will be noted that the brush A makes contact with the metallic sectors B as they pass. Each sector is connected with its corresponding spark plug C through wire D. As the sector passes over the brush a spark is produced in that cylinder and the charge fired. The high-tension cable E connects the high tension terminal of the magneto F to the brush. On the earlier forms of the Gnome engine the magneto remains stationary and in an inverted position. The gear G is keyed to the magneto shaft and engages with the large gear H which turns the cylinders.

The Wisconsin Airplane Engine.

Six cylinder engine; bore 5 in., stroke 6½ in., weight 600 lbs.; h. p. 130 at 1200 r. p. m., and 145 h. p. at 1400 r. p. m.

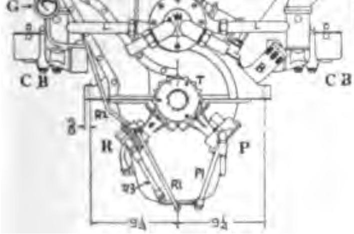
Oiling system, force feed through crank shaft. Oiling system arranged so that it will feed when climbing at an incline of 15°, and 30° when gliding.



Wisconsin six-cylinder aviation engine which has a valve action quite similar to that used on the Stutz racing cars. The camshaft is carried overhead

Valves are 3 in., placed in head at 25° angle and operated by an overhead cam shaft. Exhaust closes 10° late; inlet opens 10° late; exhaust opens 55° early and inlet closes 55° after bottom. **Cylinders cast in pairs.**

Water circulation, 6 cylinder; one centrifugal pump (W); on the 12 cylinder there are two pumps.



TWELVE CYLINDER—END ELEVATION.

Fig. 3—Wisconsin 12 cylinder "V" type engine. M1-M2 — magnetos; V—valves; O—arm operating valves; C—cam operating arms and of overhead type; CB—carburetors; IN—inlet manifolds; SP—spark plugs; B—breather; G—oil gauge; R—double oil pump. There are three oil pumps on the 12. Exhaust outlet is directly below the letter (V) above.

The cam shafts and magnetos on the 12, are driven by a train of ball bearing spur gears from the crank shaft. Double valve springs are also employed—the inner spring acting as a safety to prevent valve falling into cylinder should main valve spring break. **Ignition**, see page 909.

Carburetion; one carburetor (CB) is used on the 6 cylinder engine and two on the 12 cylinder engine.

Specifications of 12 cylinder engine; bore, 5 inch; stroke 6½ inch; weight 1000 lbs.; h. p. at 1250 r. p. m. 250; h. p. at 1400 r. p. m. 280.

T—sprocket for starting chain; P—single oil pump; P1 from oil reservoir to pump; P4 and P6—overflow from cam shaft housing.

CHART NO. 404—Gnome Engine Ignition. Wisconsin Six and Twelve Cylinder Airplane Engine.

The Sturtevant Eight Cylinder Airplane Engine.

Illustration is that of the Sturtevant 8 Cylinder V-type engine. It is made in 140 h. p. with 4 in. bore x 5½ in. stroke and 4½ in. bore with 5½ in. stroke developing 210 h. p. The normal speed is 2250 r. p. m. of crank shaft.

Valves are in head and operated by push rods; cylinders are cast in pairs; pistons aluminum alloy; rings, there are two to each piston; crank shaft, nickel steel 2¼ in. di.

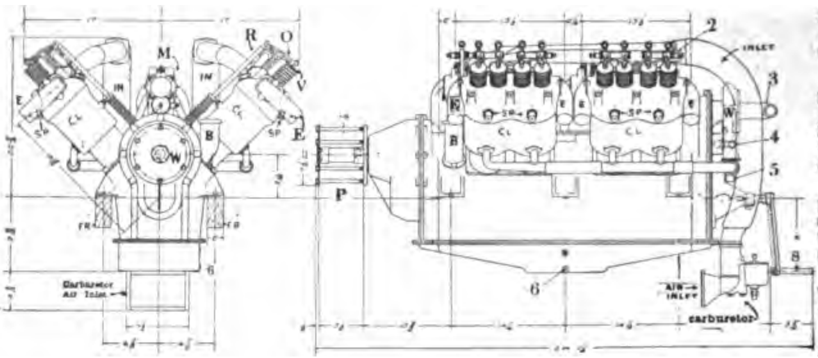
Carburetion Zenith "duplex" shown on page 182.

The inlet pipes (IN) are water jacketed. The fuel is fed by gravity.

Circulating pump (P) is shown between inlet pipes.

Engine lubrication by force feed.

Ignition by two 8 cylinder magnetos; spark plugs—two to each cylinder mounted inside of cylinders in water cooled bosses.

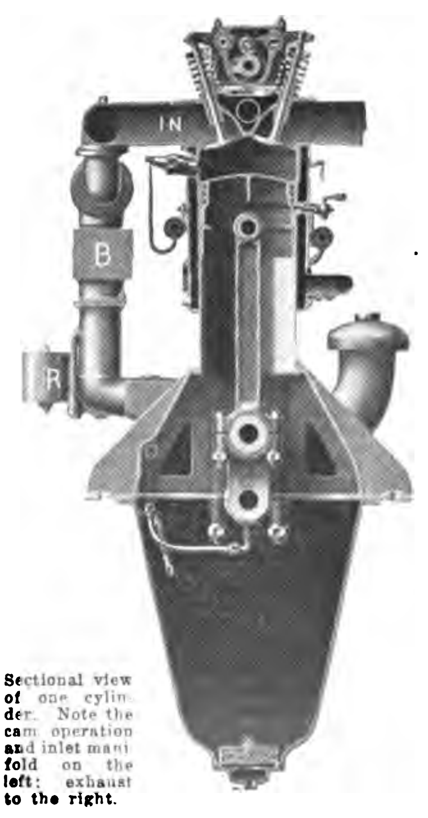


Parts of Sturtevant 8-cyl. engine; M—magneto; IN—inlet manifold; CL—cylinders; SP—spark plugs; W—water pump; B—breather; E—exhaust; FR—support to which engine is attached; R—push rod; O—rocker arm operating valve V; 6—oil outlet, auxiliary tank; 5—where tachometer shaft connects; 4—inlet to oil supply pipe; 3—double water inlet; 2—water outlet 1¼ in.; S—starting crank.

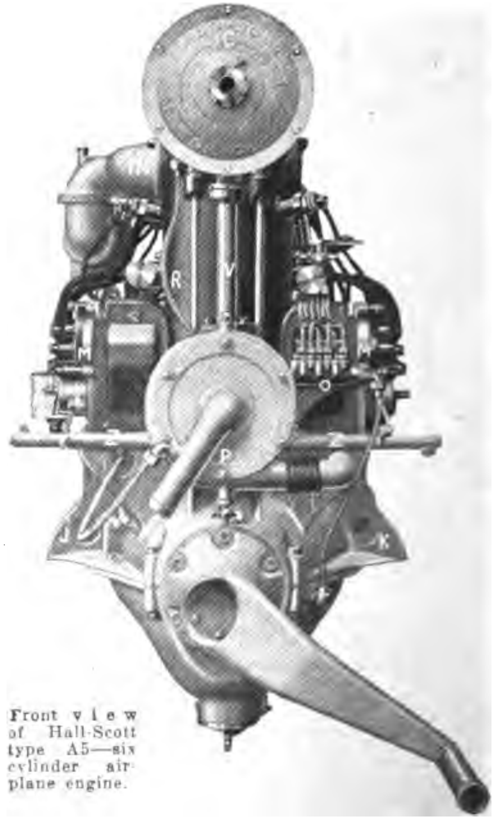
The Hall-Scott Airplane Engine

is described on pages 913 to 916. Two views are shown below of the type A-5—six cylinder engine. The four cylinder engine, type A7 and A7a are similar in construction.

Name of parts lettered: B—oil jacket circulating oil around inlet manifold to cool it; R—pipe for draining oil from cam-shaft housing back to crank case; J—water pipe from pump to inlet manifold (see page 914); K—pipe from auxiliary oiler (O) to crank case, for cylinder lubrication; M—magnetos; Z—spark advance lever rod; C—cam shaft housing cover; R—carburetor; IN—inlet pipe; V—vertical drive shaft housing.



Sectional view of one cylinder. Note the cam operation and inlet manifold on the left: exhaust to the right.



Front view of Hall-Scott type A5—six cylinder airplane engine.

CHART NO. 405—The Sturtevant Eight Cylinder "V" Type Airplane Engine. The Hall-Scott Six Cylinder Airplane Engine—see also pages 913, 914, 915.

The Hall-Scott Airplane Engines.

Are made in four types as follows: type **A-7**, 90 h. p., 4 cylinder; type **A-7a**, 100 h. p., 4 cylinder; type **A-5**, 125 h. p., 6 cylinder; type **A-5a**, 150 h. p., 6 cylinder. This h. p. is developed at 1300 r. p. m.

Cylinders are cast separate and made from a mixture of grey and Swedish iron. Inner walls of cylinders and valve seats are hardened and ground.

Valves.

Valves are overhead operated by an overhead cam-shaft.

Valves are placed in head of cylinders at a slight angle. The valves are operated by an overhead cam shaft enclosed in a housing (see page 914). The valves are one-half the diameter of the cylinder bore and are made of Tungsten steel.

The type A-5, 6 cylinder engine has a bore of 5 in. and 7 in. stroke. Weight of type A-5 complete, is 565 lbs.

Cam Shaft.

Cam shaft is made of chrome nickel forging and the four cam shaft bearings are made from Parson's white brass. A small clutch is milled in rear end of shaft to drive the revolution indicator (tachometer). **Cam shaft** is enclosed in an aluminum housing and driven by a vertical shaft with bevel gears. Oil is forced through end of this shaft permitting surplus supply to flow back to crank case.

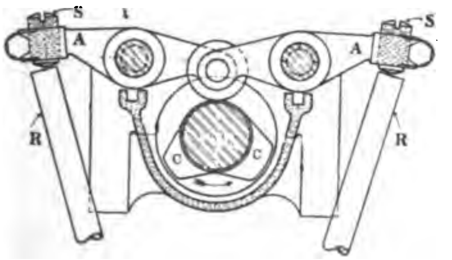


Fig. 1—Setting of adjustable set screw (S) in rocker arm (A) in relation to the valve stem (R). In other words the method of setting valve-clearance on all types of Hall-Scott engines. The clearance should be .020" when valves are seated.

Valve and Ignition Timing.

Valve timing on type A-7 and A-5 engine is as follows; exhaust closes 15° late; inlet opens 10° late; exhaust opens 45° early; inlet closes 40° after bottom. **Magneto** is set to fire 27° before top of compression stroke—advanced. **Firing order:** 4 cyl. engine, 1, 2, 4, 3; 6 cyl., 1, 5, 3, 6, 2, 4.

Valve timing in type A-5a and A-7a engines: exhaust closes 10° late; inlet opens 15° late; exhaust opens 54° early; inlet closes 45° after bottom. **Magneto setting** same as A-7 and A-5.

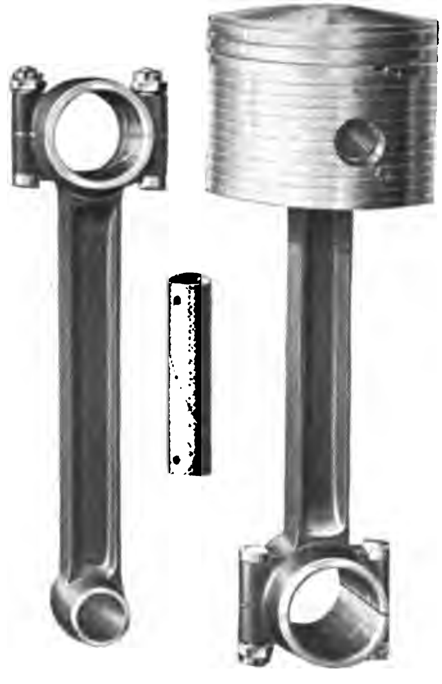
Curtiss OX2 valve timing: Ex. opens 50° before bottom; Ex. closes 10° after top; inlet opens 14° after top; inlet closes 48° after bottom. Average valve stem and rocker arm clearance .010".

Grinding Valves.

To grind the valve seats, place a bar, having two holes through same, down over the two cam shaft housing hold-down studs opposite the valve to be removed. Replace the two nuts. Remove the cotter pin in valve stem under the valve spring cup. Using a special Hall-Scott valve tool which can be slipped under the bar, it will be easy to force the valve cup and spring down so the small key can be readily removed. This will allow the removal of both valve spring and cup. Take out the valve and clean it thoroughly, also noting whether or not the stem is clean, or otherwise in good condition. Replace the valve and grind by rotating it back and forth with a screw driver, the grinding paste being between the valve and the seat. Care should be taken to raise the valve from its seat frequently while grinding. This prevents grinding a groove in the seat.

Connecting Rod.

The connecting rods are I-beam type very light. Piston end is fitted with gun metal bushing while crank pin end carries two bronze serrated sleeves tinned and babbitted hot. Laminated shims are placed between cap and rod for adjustment.



Pistons.

Pistons are aluminum alloy. Note piston pin is placed very low in order to keep heat from piston head and away from upper end of connecting rod, as well as to arrange them at the point where piston fits cylinder best.

The Magnalite piston is used to a great extent. Piston rings are ¼ inch wide. There are 3 to a piston.

Oiling System

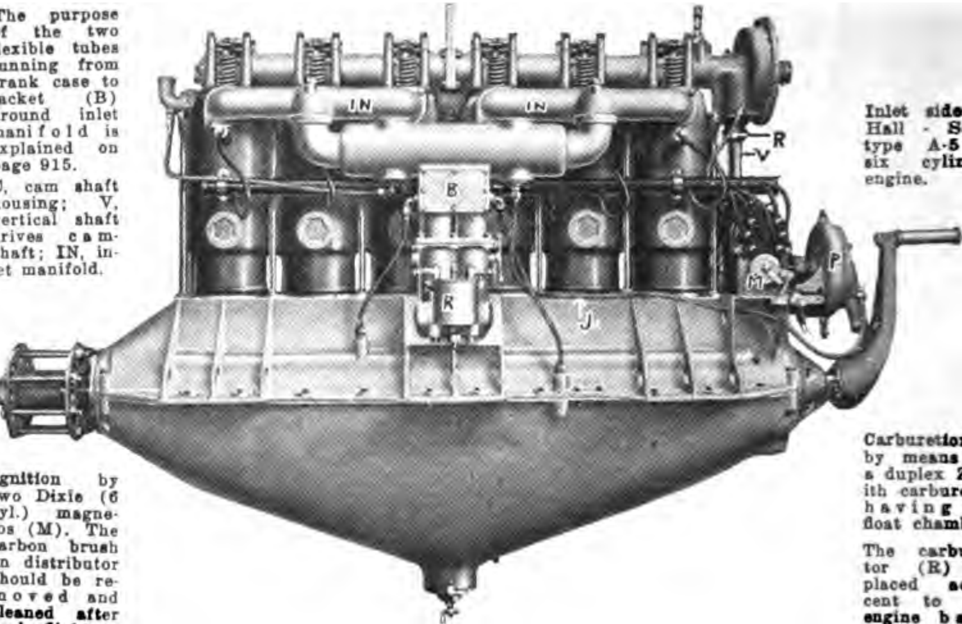
Oiling system is known as the high pressure or force system. A gear pump is located in the inside lower portion of the oil sump—see page 915.

Gasoline System.

Air pump is power driven and maintains pressure in the gasoline tank and is a similar system to Packard, page 854. A hand pump is also provided so that pressure can be obtained before engine starts.

The purpose of the two flexible tubes running from crank case to jacket (B) around inlet manifold is explained on page 915.

C, cam shaft housing; V, vertical shaft drives cam-shaft; IN, inlet manifold.



Inlet side of Hall - Scott type A-5 — six cylinder engine.

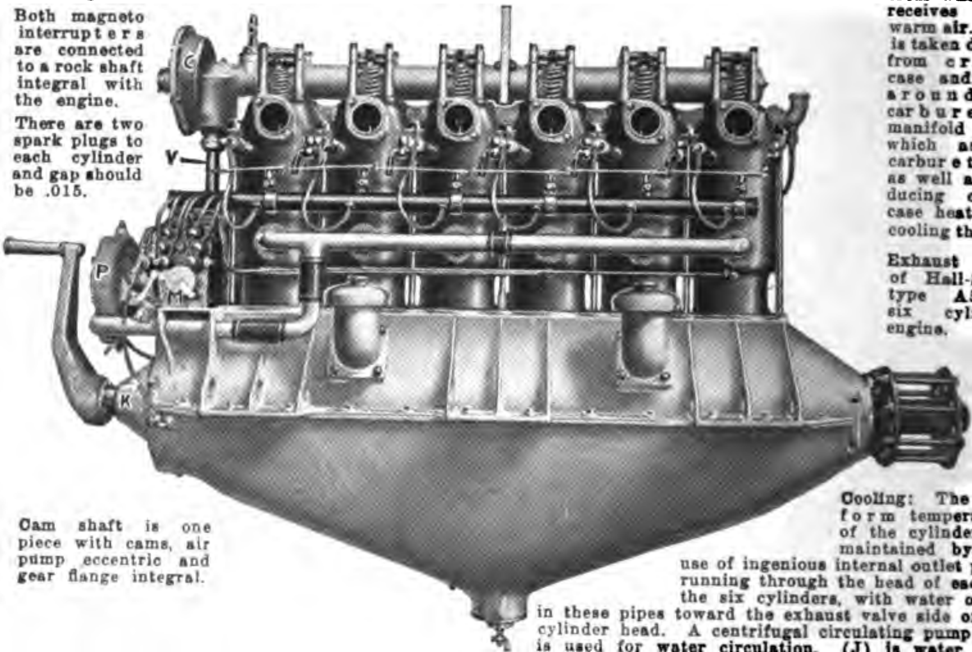
Ignition by two Dixie (6 cyl.) magnetos (M). The carbon brush on distributor should be removed and **cleaned after each flight.**

Both magneto interrupters are connected to a rock shaft integral with the engine.

There are two spark plugs to each cylinder and gap should be .015.

Carburetion is by means of a duplex Zenith carburetor having one float chamber.

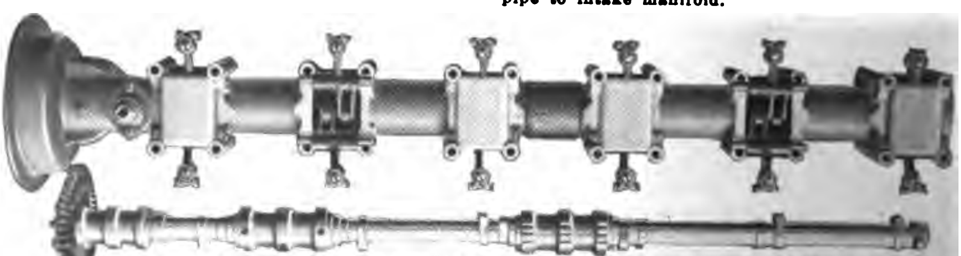
The carburetor (R) is placed adjacent to the engine base from which it receives its warm air. Oil is taken direct from crank case and run around the carburetor manifold (B), which assists carburetion as well as reducing crank case heat and cooling the oil.



Exhaust side of Hall-Scott type A5 — six cylinder engine.

Cam shaft is one piece with cams, air pump eccentric and gear flange integral.

Cooling: The uniform temperature of the cylinders is maintained by the use of ingenious internal outlet pipes running through the head of each of the six cylinders, with water outlet in these pipes toward the exhaust valve side of the cylinder head. A centrifugal circulating pump (P) is used for water circulation. (J) is water inlet pipe to intake manifold.



Cam shaft housing is aluminum. Cam-shaft is placed overhead and driven by a vertical shaft driven by bevel gears G6 and gear G7 on crank-shaft, see page 915

CHART NO. 406—Hall-Scott Six Cylinder Airplane Engine—continued.

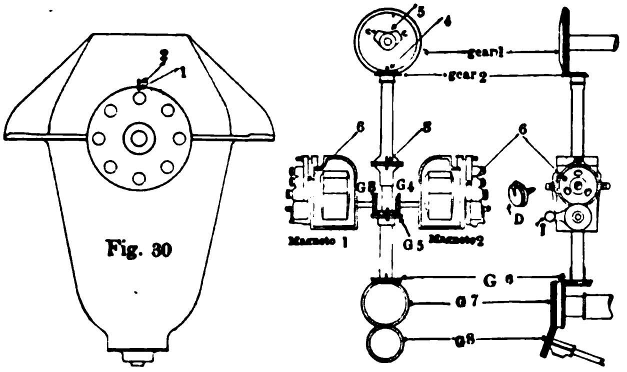


DIAGRAM OF MAGNETO AND CAM SHAFT DRIVING GEARS IN HALL-SCOTT, TYPE A-5, 125 H. P. ENGINE.

Magneto and Cam-Shaft Driving Gears—Hall-Scott.

5—shows position of no. 1 cylinder cams when no. 1 piston is on top of dead center of compression stroke. When timing, the mark (1) on crank shaft flange (fig. 30), is brought true with mark (2) on crank case. It is stamped "T. C. 1-6," meaning, 1 & 6 cylinders are on dead center. A mark (3) is provided on vertical shaft flanges. These must be set in dead center position as shown. The cam shaft with housing is now slipped into place. Note mark (4) on cam shaft gear—this should line up with mark on bottom of cam shaft gear housing.*

Magneto installation, after assembly as above, take magneto marked (L) at base (meaning left hand), remove distributor, turn magneto shaft until hole with red ring, lines up with red mark on magneto body. Insert magneto left hand and magneto right hand. After gears are meshed, be sure holes on gears are directly in line with red marks in magneto body. Both magneto breaker points should synchronize or break at same time.

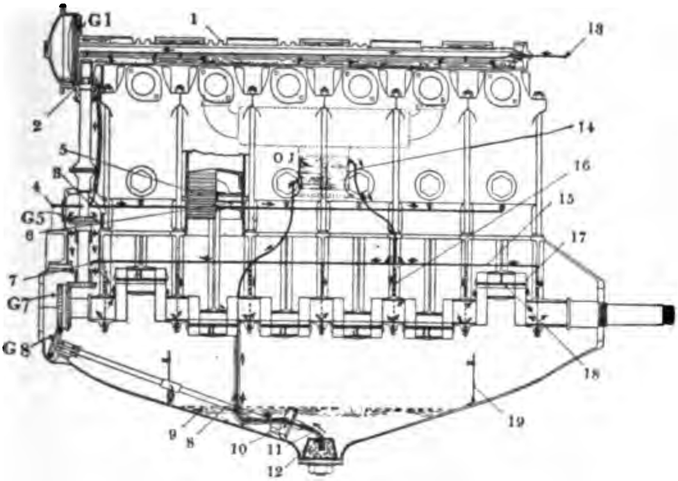

Diagram of Hall-Scott type A-5 engine oiling system. Heavy dotted lines and arrows show direction of oil flow. Note the method of cooling the oil—see 8 and 14.

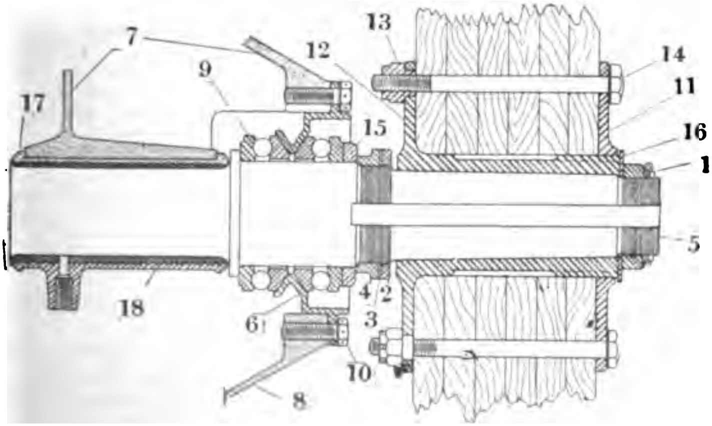
Oil is first thrown from strainer (12) by pump, to long jacket (OJ) around inlet manifold, thence forced with a pressure of from 5 to 30 lbs. to distributor pipe (15) in crank case. An independent oiling system using a small direct drive rotary oiler, feeds oil to each individual cylinder.

The oil is cooled by circulating it around the long inlet manifold jacket in such a manner that the carburetion of gasoline cools it.

Oiling Diagram.

1—excess oil from bearings flows into reservoirs between; 2—oil overflows into overflow pipe; 3—oil comes out of overflow pipe and after oiling gears, excess oil flows down through magneto gear housing into sump; 4—individual oil pipe from distributor to each cylinder, automatically injects oil onto pistons as each one passes oil port; 5—oil rings on piston, oil circulates into hollow wrist pin, oiling upper end of connecting rod; 6 — section through piston, showing hollow wrist pin; 7—relief valve and by-pass at end of main oil pipe, through which excess oil flows back into sump; 8 — oil is pumped through pipe to cooling reservoir on gas intake manifold; 9—reservoir of oil in sump; 10—oil pump; 11—oil suction to pump; 12—oil strainer and clean out plug; 13—oil comes from auxiliary hand pump into hollow camshaft; 14—oil flows from cooling reservoirs down into main oil pipe; 15—main oil pipe; 16—individual leads to bottom of each main bearing cap; 17—excess oil from bearings drips into scuppers on crank cheeks; 18—hollow crank pin, which oils connecting rod bearing; 19—baffle plates.



Propeller Bearing.

Details of propeller double thrust bearing used on the Hall-Scott engines. For thrust or tractor type propellers.

1—nut in crank shaft; 2—nut on thrust lock; 3—washer; 4—nut on inner thrust; 5—crank shaft; 6—collar thrust; 7 — upper crank case; 8—lower crank case; 9 — thrust bearing; 10—screw for thrust collar; 11—propeller flange; 12—crank shaft flange; 13—propeller bolt nut; 14—propeller bolt; 15—spacer for thrust bearing; 16—washer for crank shaft nut; 17-18—rear bushing for rear bearing of engine crank shaft.

CHART NO. 407—Details of Hall-Scott Engine. Propeller Bearing.

See page 295 for speed of cam-shaft and magneto of a six cylinder engine. When crank-shaft turns once; magneto armature turns 1½ rev.; distributor on magneto ½ rev.; cam-shaft ½ rev.

*The gear clearance is .020" except gear G7 & G6 which is .010"; bearing clearance is .001" and spark plug gap .01

Mercedes Engine.

Two Mercedes engines of 260 h. p. each are used on the Gotha airplane. These are of the six-cylinder vertical tandem type with the cylinders made singly and their waterjackets connected together by joints. There is a slightly greater distance between cylinders Nos. 3 and 4 than between the other cylinders.

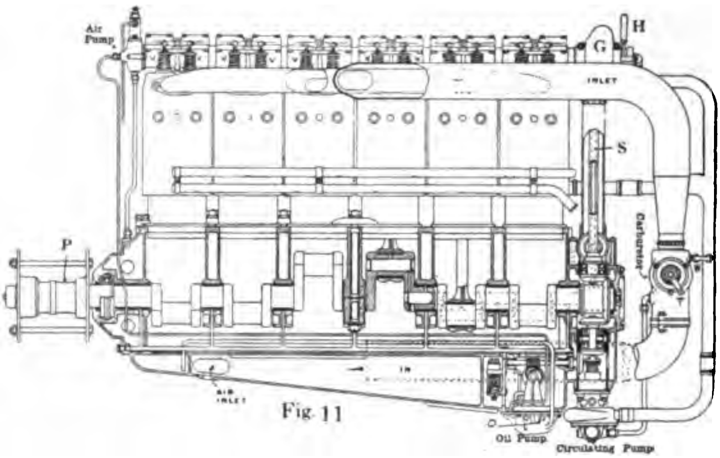


Fig. 11

Cylinders; the water-jacket of each cylinder is connected by a joint to the jacket of the adjacent cylinder, and each cylinder is separately secured to the crankcase.

Cylinder bore, 160 mm. (6.3 in.), stroke, 180 mm. (7.09 in.), and the engine develops from 258 to 260 h. p. at 1400 r. p. m.

Cylinders are of the "built-up" type (fig. 13), composed of steel, machined. Sheet steel is pressed to form water jacket and is acetylene welded.

Cylinder barrels are screwed into cylinder head at (T). They are machined from forgings and cylinder walls taper from 3.5 mm. at top to 6 mm. at bore or flange.

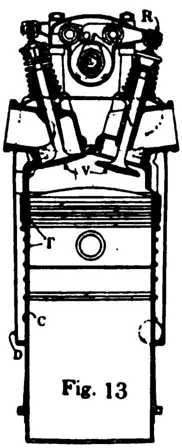

Fig. 13

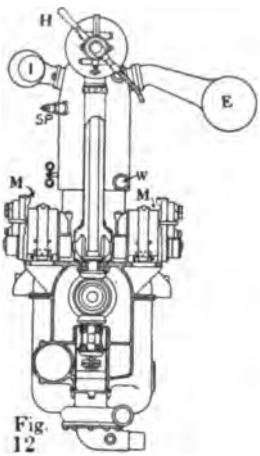

Fig. 12

Stiffening ribs (C) are arranged as shown.

Cylinder heads are machined from steel forgings, and into these are built 4 valve pockets, also inlet and exhaust ports. Seatings for valves are machined in the cylinder heads. Valve pockets are machined from steel and are acetylene welded into heads. Exhaust valve guide has a greater water space than inlet.

The hourly consumption is equal to 76 liters (20 gal. of gasoline) and five liters (1.32 gal.) of oil.

A single carburetor is installed, instead of the dual or two combined carburetors on the 170 h. p. engine and the two separate carburetors on the 235 h. p. The carburetor is located at the forward end of the engine and draws its air through the crankcase, through "air inlet," thence through "in," which tends to heat the mixture and to keep the crankcase cool. A single inlet pipe of enormous size extends from the carburetor. Carburetor is water jacketed at (W).

Ignition is by two Bosch ZH6 magnetos (M), connected to the camshaft (fig. 12) which latter extends horizontally across the tops of the cylinders.

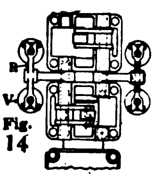

Fig. 14

Spark plugs—there are two, to each cylinder (SP).

Valves; there are four valves in each cylinder—see figs. 13 and 14. The two exhaust valves are on one side and two inlets on opposite side.

When starting—a compression relief mechanism with a hand lever (H, figs. 11 and 12) is moved to the side, which displaces the camshaft by throwing into play, small cams located opposite the exhaust cams, which keep the exhaust valves open during part of compression stroke, thus reducing the compression.

Cooling is by water. The water pump driving spindle is lubricated while in flight by means of a ratchet-driven grease gun or pump, worked by a cable and lever from the pilot's seat.

An electrical tachometer is driven at engine speed from the rear end of the camshaft, through a flexible shaft.

Fuel—an air pump is driven from front end of cam shaft, for providing air pressure to gasoline fuel tank.

Oiling system: forced lubrication is, of course, employed. A four-throw eccentric-driven plunger pump is fitted. An "auxiliary" sump in the front end of the crank case is embodied, and small supplementary pump plungers, which work in conjunction with the main oil pump, feed fresh oil into the system from the service oil tank, which is connected to oil pump at (O), fig. 11.

CHART NO. 408—The Mercedes 260 H. P. Airplane Engine as used on the Gotha Biplane, fig. 2, Chart 399. (Automobile and Automotive Industries.)

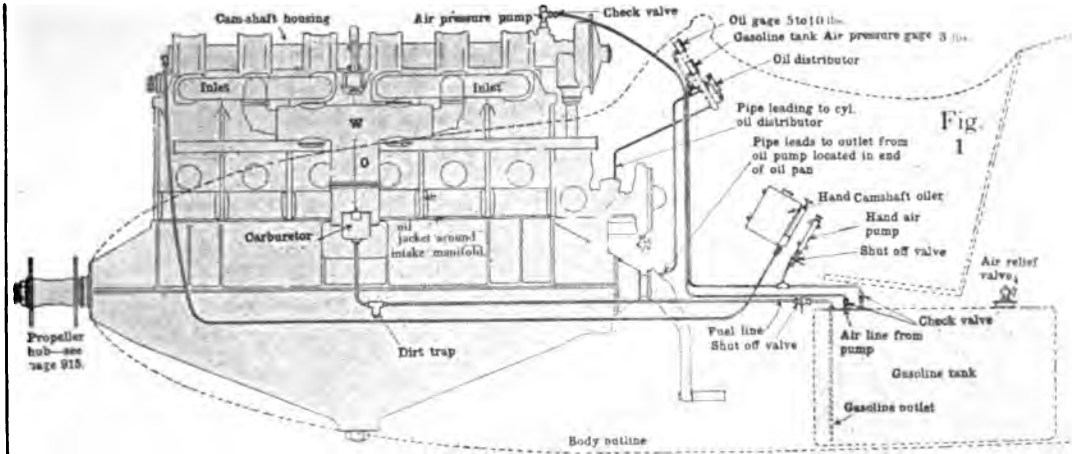

Fig 1. Illustration showing the engine installation of the Hall-Scott, type A-5, 125 h. p. six cylinder engine. Also the gasoline system and auxiliary cam shaft oiling system. Note gasoline air pressure pump is operated by cam shaft. There is also an auxiliary hand air pump. The air pressure (not under 8 lbs) forces the gasoline through gasoline outlet pipe to carburetor. On some systems another small auxiliary tank is provided above carburetor, about 2 feet, to which the gasoline is forced by air pressure and then the gasoline is fed to carburetor by gravity. Note the auxiliary hand lubricator for cam-shaft. A water jacket (W) surrounds the inlet manifold to heat the mixture per page 157. The lubricating oil circulates around inlet pipe in jacket (OJ), see page 915.

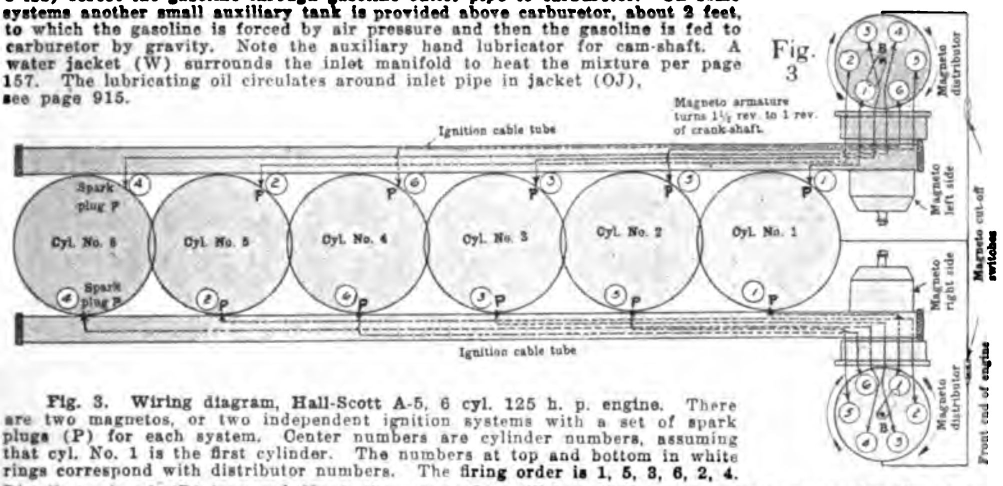

Fig. 3. Wiring diagram, Hall-Scott A-5, 6 cyl. 125 h. p. engine. There are two magnetos, or two independent ignition systems with a set of spark plugs (P) for each system. Center numbers are cylinder numbers, assuming that cyl. No. 1 is the first cylinder. The numbers at top and bottom in white rings correspond with distributor numbers. The **firing order is 1, 5, 3, 6, 2, 4.** Distributor brush (B) is on cyl. No. 1, the next to **fire will be cyl. No. 5 (distributor connection No. 2), and** etc. Both systems can be used or each separately **by operation of magneto switches.**

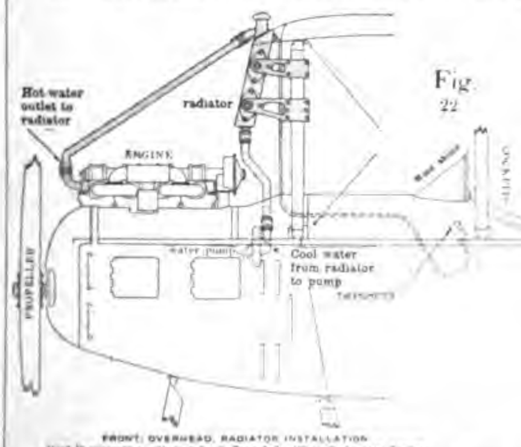

Fig. 22: Illustrates how a single radiator is installed in the front, overhead and water connection thereto. Note the thermometer is the distance or extension type "Motor meter" described on page 921.

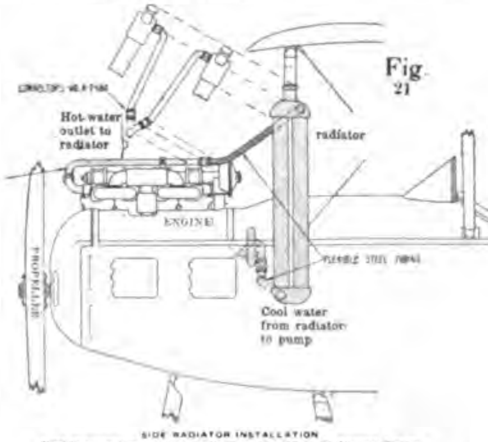

Fig. 21: Illustrates how two radiators are installed, one on each side of engine. These illustrations are Hall-Scott type A-7a, 100 h. p. four cylinder engine.

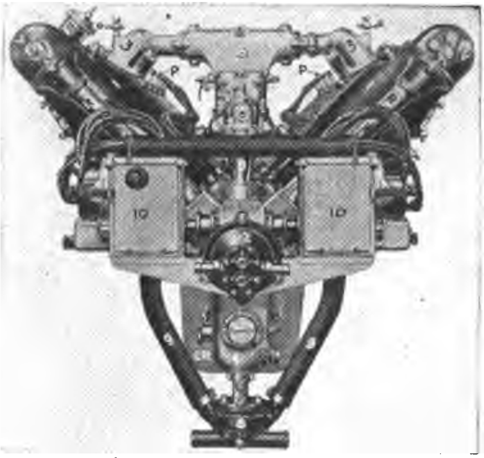
CHART NO. 409—Gasoline System; Ignition, Firing Order and Radiator Installation on Hall-Scott Airplanes.



Hispano Suiza Engine.

Model E, 180 h. p. V-type 8 cylinders. Two sets of spark plugs. Two magnetos are carried at front end. Valves are actuated from cams by an overhead cam shaft on each cylinder block and the carburetor is hung centrally. Bore is 120 m. m. and 130 m. m. stroke (approximately 4¾x5⅛). Weight is approximately 450 pounds including magnetos, carburetor, but without radiator or exhaust pipes. Speed 1,450 r. p. m. Pistons aluminum alloy. Connecting rods forked. Crank shaft has 5 bearings. Illustration shows the rear view of engine.

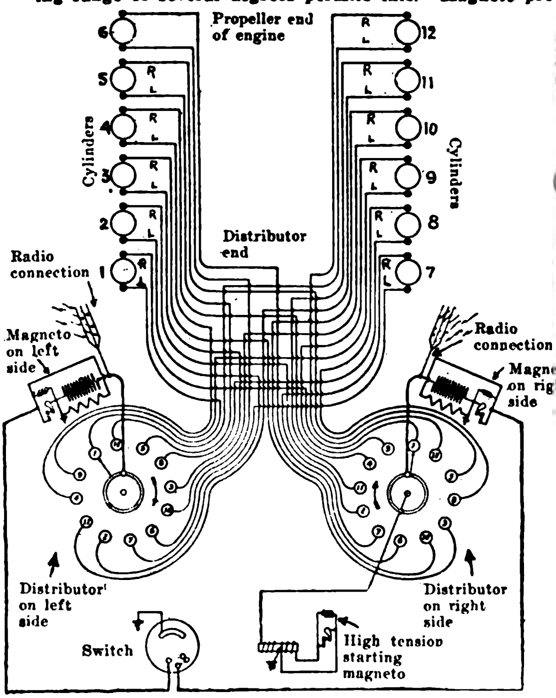
Name of Parts.

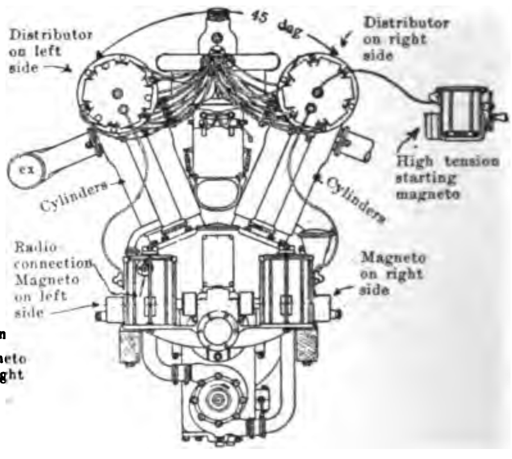
1, cylinders; 3, inlet manifold; 5, part of inlet manifold with hot water jacket; 6, carburetor duplex type; 8, water pump; 9, water pipes; 10, magnetos; 12, oil circulating pump; V, overhead cam shaft housing; E, exhaust; B, breather pipe to crank case; P, spark plugs; R, housing for shaft driving overhead cam-shaft; CR, crank case, lower part; Cylinders are set at an angle of 90 degrees.

Wiring Diagram of a Twelve Cylinder V-Type Airplane Engine Using Separate Distributors, Two Magnetos and Showing Radio Connections.

On airplane engines of the 12 cylinder V-type with cylinders set at 45° angle between the two rows of cylinders, magnetos of the high-tension type are sometimes used, with distributors driven separately and employing a separate high-tension magneto for starting—see illustrations below and page 922.

The magnetos operate 1½ times engine crank-shaft speed. The distributors revolve 1 rev. to 2 of engine crank. The distributor segments are spaced 37½° and 22½° apart, alternately. For automobile work this would cause an uneven impulse at very low speeds, but for airplane work where engine is running at full speed, it is not noticeable. The advantage for airplane work is to use a smaller hood and reduce head-resistance. If distributor revolves ½ speed of engine crank-shaft, then firing relative to crank would be 75° and 45°. Magneto armature produces current at 67½ and 112½ degrees—a sparking range of several degrees permits this. Magneto produces 4 sparks per revolution.





Two magnetos are here used, each producing a spark in each cylinder at the same time. A separate high tension geared up magneto for starting by hand cranking is an auxilliary source. A trailing pin in distributor is set later than main distributor brush.

The magnetos are commonly set on the engine so that the spark occurs from 23 to 28° ahead or in advance of dead center position of piston.

Referring to meaning of R and L above, note R cable from spark plugs connect with distributor on the right and L cables with distributor on the left.

Firing order of above twelve cylinder engine is 1, 12, 5, 8, 3, 10, 6, 7, 2, 11, 4, 9—refer to numbers to the side of cylinders.

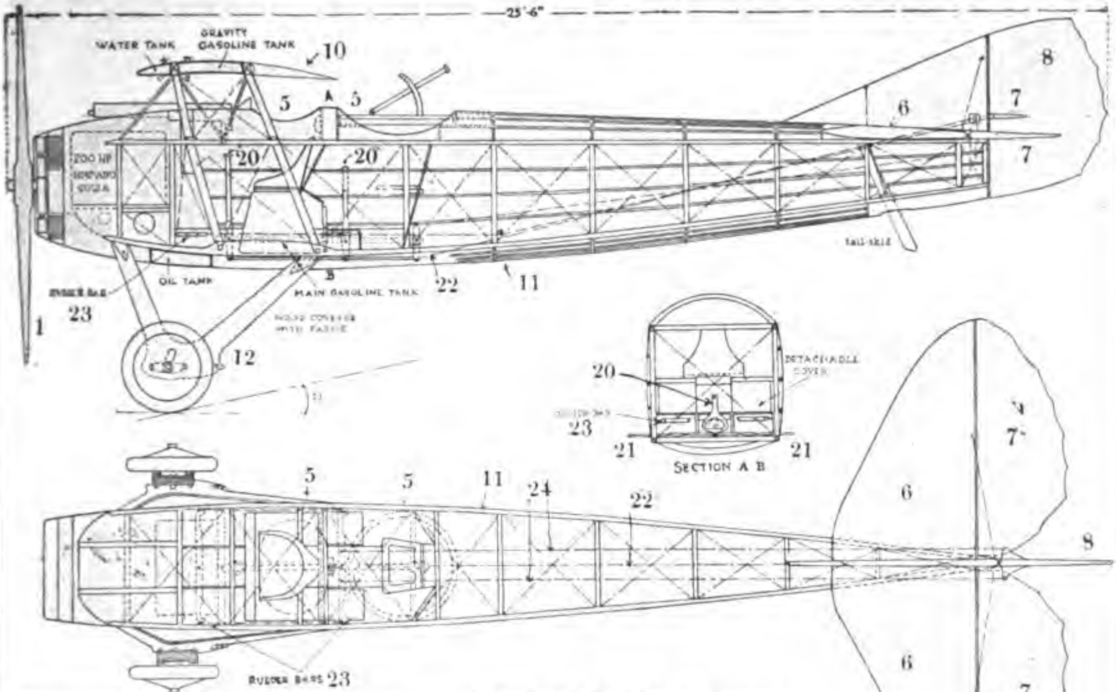
Firing orders 8 cyl. airplane engines; Sturtevant, 4L, 1R, 2L, 3R, 1L, 4R, 3L, 2R (see diagram fig. 2, page 131); Hispano-Suiza, 4L, 1R, 3L, 2R, 1L, 4R, 2L, 3R; Curtiss OX2, 4L, 4R, 3L, 3R, 1L, 1R, 2L, 2R.

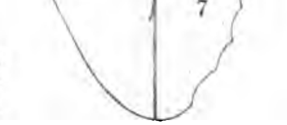
Castor oil is considered an ideal lubricant for airplanes of both the revolving and stationary cylinder type, for the following reasons as stated by The Baker Castor Oil Co., N. Y.: higher viscosity, lower heat conductivity, no carbon, higher fire test, higher flash test, lower cold test and will not mix with mineral oil.

CHART NO. 410—Hispano Suiza Airplane Engine. Wiring Diagram 12 Cylinder V-Type Airplane Engine. Firing Order 8 Cyl. Engines. Castor Oil.

*Note the 12 cylinder engine page 135, has cylinders 60° angle. (Two lower illustrations courtesy Motor Age.)

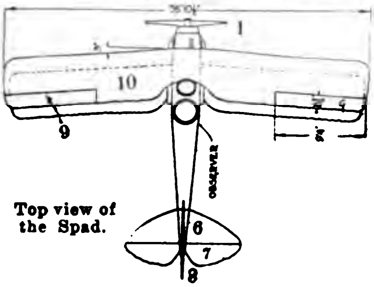
The above wiring method is the same as used on the Liberty Engine, except Delco coil and battery, distributor and timer ignition system is used instead of magnetos—see pages 938 and 939.





The Spad Two-Seater Biplane.

Measurements: Upper wing span 36.7 ft.; chord 4.69 ft. The gap is 4.38 ft. and the stagger 1.31 ft. Angle of incidence of upper plane is 2.8 deg. in center and 2.5 deg. at the tip, while the lower plane has a uniform angle of 1.5 deg.



Top view of the Spad.

Dual control: For operating the ailerons, (9) the movement of the control shaft is transmitted by means of a lever (20) to a rocker supported in a position between pilot's and observer's cockpits (5). The rods—which rest in the bottom wing—engage with a downward projection of the rocker.

Engine: Vee type Hispano-Suiza engine, which develops 200 h. p. at 2,000 r. p. m. The two-bladed air screw is geared down, by means of gearing incorporated with engine in ratio of 4:3.

Fuel: A main fuel tank with pressure system has a capacity of 37 gal. and forms the pilots seat, while a gravity tank holding 2.65 gal. is mounted in the upper wing, between the spars. The fuel capacity is sufficient for two hours flight. **Oil tank** holds 4 gal. and rests on floor of body behind engine. Bottom of oil tank has pressed on ribs for cooling the oil. **Radiator** is provided with shutters and forms nose of fuselage. **Instruments;** on the right, the starter and hand operated air pump. In center; two switches, one three-way cock for pressure tank and connecting with either hand or engine air pump, one three-way cock handle for turning on or off gasoline from tank to carburetor, one tap for turning engine air pump off pressure tank, one manometer (water circulating gage) and revolution indicator. On the left: the gas lever, lever for regulating the mixture, and lever for operating radiator shutters. No provision is made for advancing or retarding the magneto. Weight of machine empty, but including the cooling water 1680 lbs. **Item weights;** engine 480 lbs.; cooling water 69.6 lbs.; wings 370.0; elevator and rudder 43.8; body etc., 710.0; total 1673.4 lbs. **Loading;** pilot and observer 374.0 lbs.; armament 179.0; instruments, etc. 7.7; fuel 264.0 or total 824.7.

Types of Airplanes.

Are divided into types as follows:

Combat machines; small fast single-seaters. Wing spread of from 20 to 25 ft., speed 125 to 135 m. p. h., 450 lb. carrying capacity. Climbing speed 10,000 ft. in from 8 to 12 min. The spad, Nieuport, Morane, Curtiss-Triplane, S-E-5, Sopwith, Dolphin, and Iserman Albatross single-seaters are examples.

Reconnaissance and photograph machines; slow flying—used for artillery spotting, map making and general reconnoitering. Wing spread from 40 to 60 ft., speed 80 to 100 m. p. h., 800 to 900 lb. carrying capacity. Two or three seaters. Climbing speed 10,000 ft. in 12 to 25 min. Examples are; De Haviland, Bristol, Voisin and Farman.

Battle planes; a two or three passenger machine, driven usually by one large or two fairly good-sized engines. Equipped with a number of machine guns, sometimes a cannon. 70 to 85 m. p. h. The Voisin an example.

Bombers; same general type as reconnaissance machines, but slightly larger. Vary from 45 to 90 ft. in wing spread, carry two to twelve people in addition to war load of bombs and fuel. Speed 75 to 100 m. p. h. Radius of operation 500 to 1000 miles. Climbing speed 7000 ft. in 30 min. Examples: Handley-Page, Caproni, Breguet, the Coudron (twin-engine, French), German Gotha, Friederichshafen, German A E G, and big Curtiss boats.

Naval work; flying boats and hydroaeroplanes of various sizes are used. They compare with reconnaissance machines, 90 to 100 m. p. h. The large 92 ft. wing spread Curtiss flying boats are good examples.

CHART NO. 411—The Spad Two-Seater Biplane. Types of Airplanes.

(Automotive Industries, The Automobile). **See page 902 for name of numbered parts.**

Altimeters.

Two types of altimeters in general use, for determining the altitude, are the Mercury Barometer and the Aneroid Barometer.

Mercury Barometer, fig. 1, indicates altitudes by the rising or falling of the mercury in the glass tube. Note the bulb is filled with mercury and opening (OP) permits the outside atmospheric pressure to act upon the mercury. At sea level the mercury would stand at point indicated at 30 in. high, marked sea level. At an altitude of 19,000 feet the mercury would drop to point indicated, because the atmosphere is less dense or lighter, being only 7.3 lbs. per sq. in. which pressure is not sufficient at (OP) to force the mercury as high as at sea level. Thus the mercury drops, as altitude increases.

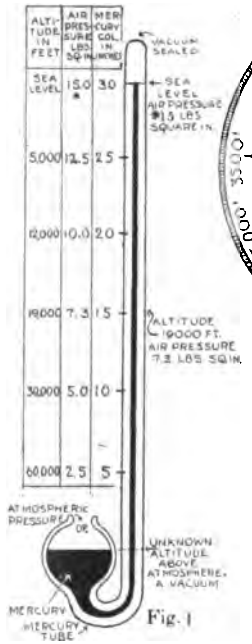


Fig. 1

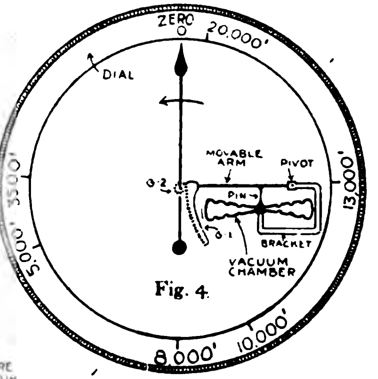

Fig. 4.

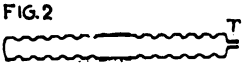
If a height could be reached where there is no air pressure at all, then the mercury would drop the full 30 inches, or to the level of mercury in bulb, indicating no pressure at all at (OP). Note the mercury column does not drop in direct ratio to change of altitude, because higher the altitude, the atmosphere is less dense, and a further distance is required to travel in order to obtain the same variation in pressure. For example, starting from sea level, a movement up and down of 900 feet will cause mercury column to move down and up one inch, whereas, at an altitude of 40,000 feet it would require movement up and down of 4,000 feet to represent 1 inch movement of the mercury column.

The mercury barometer can also be read in inches, for instance, mercury at 25 inches would represent an altitude of 5,000 ft. and air pressure of 12.5 lbs. per sq. inch.

When going below sea level, say down in shafts, the atmosphere increases with the depth, equal to about 1 inch rise of the mercury in the barometer for each 900 feet increase in depth—**going above sea level** air becomes lighter and mercury drops.

****Aneroid Barometer, fig. 4,** differs in principle. **Fig. 2** shows the vacuum chamber before the air is removed. It consists of a metal box of two thin, circular and flexible metallic discs, corrugated on each surface and forming a closed box. If air is pumped out at (T) and sealed, a vacuum is formed inside and the top and bottom would collapse as in fig. 3, because there would be no air pressure inside, yet, on the outside, if at sea level, the air pressure on top and bottom would be *14.7 lbs. per sq. inch, hence reason for its closing together as shown in fig. 3, after all air is withdrawn or a vacuum formed.

FIG. 2



If this vacuum box or chamber fig. 3, is taken to a height where the altitude, say is 19,000 ft. above sea level, the air would be less dense or much lighter, being only 7.3 lbs. to the sq. in. Therefore as the pressure outside of vacuum chamber is not as great, the flexible discs would tend to open out, due to the flexibility of the metal top and bottom of vacuum chamber, trying to assume normal position.

FIG. 3

If an altitude could be reached where there is no air pressure at all, which is an unknown height, the vacuum chamber discs (top and bottom) would open out to their normal position, as outside pressure would be nothing and inside pressure nothing. Therefore the amount of air pressure exerted on the outside of the vacuum chamber causes the top and bottom to move, this movement is taken advantage of mechanically, as shown in fig. 4.

Fig. 4: At sea level the vacuum chamber would be almost collapsed as the *14.7 lbs. pressure outside would force discs together. Therefore a †simplified method is shown, which will indicate the altitude as the air-craft rises. For instance, at an altitude of 19,000 ft. the air pressure outside of the vacuum chamber being 7.3 lbs., the discs of chamber will open out and in so doing, will cause pin to raise pivoted movable arm, causing rack gear (G1) to turn small pinion gear (G2) attached to needle.

The dial is not fixed, but can be turned. It can be set at any altitude or atmospheric pressure. For instance, at various localities the altitude varies, as also does the atmospheric pressure. Therefore the zero (0) point on dial is turned to where needle stands at time of starting the flight and the altitude is determined by the graduations from zero point.

Meaning of Sea Level.

Sea level is a term used to designate a starting point for altitudes. At sea level the atmosphere is more dense and heavier than at greater altitudes. The pressure of the atmosphere at sea level is approximately *14.7 lbs. per sq. inch.

Atmospheric pressure at various altitudes, graduated 5 inches apart, is shown in table, fig. 1. Other distances not marked are: atmospheric pressure at 3,000 feet would be 13.50 lbs. per sq. in.; at 10,000 feet, 10.25 lbs.; at 12,000 feet, 10.00 lbs.; at 19,000 feet, 7.3 lbs.; at 20,000 feet, 6.25 lbs.; at 29,000 feet, 4.85 lbs.; at 37,000 feet, 3.15 lbs.; at 45,000 feet, 2.75 lbs. per sq. inch. For a rough approximate, the pressure decreases ½ pound per square inch for every 1,000 feet of ascent.

Highest Altitude Reached.

On August 12, 1909, Lieutenant Mina of the Italian army, and Mario Piacenzo, in the balloon Albatross, ascended to a height of 11,800 metres (seven miles and 1,754 feet). A spherical bag, with a capacity of 2,000 cubic metres was used. On this occasion, however, the bag was inflated only to the extent of 1,200 cubic metres. The travelers carried with them a large quantity of oxygen to permit breathing in the rarefied atmosphere. At the greatest altitude, they experienced a temperature of 24° below zero, Fahrenheit.

The Albatross appears to have exceeded all previous high records. Eleven thousand and eight hundred metres is equal to 38,714 feet, and the record for height has been 37,000 feet, made in 1862 by two Englishmen, Coxwell and Glaisher. The highest point is Mt. Everest, Northern part of India, 29,002 ft.

Highest altitude record for airplane, by Capt. Lang, Ipswich, England, Jan. 2, 1919, 30,500 ft.

HART NO. 412—Method for Determining Altitudes.

*The figures in table, fig. 1 are based on an air pressure at sea level of 15 lbs. per square inch. The correct pressure is approximately 14.7 lbs. per sq. inch. **Aneroid is a Greek compound, expressing, "without fluid." †Fig. 4 is not exact construction, but explains the principle. See page 921 for exact likeness of an Altimeter dial.

ALTIMETER

Dial of the Short & Mason Altimeter. Needle turns to left. Reading in thousands of feet, as 1, means 1,000 and so on around to 17, which is 17,000 feet. Lower reading is merely a continuation after 17.

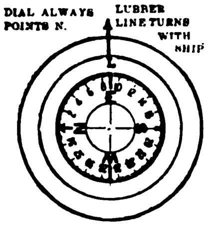


FIG. 38 AIR COMPASS

Air Compass: Dial is supported on a pivot and always points N. Numerals are every 20 degrees. The last cipher is omitted to save space, as 2 means 20, 30 means 300 degrees. etc. From N to N is 360°. The bowl turns with ship and lubber line (L) being on bowl turns with it. Lubber line is now opposite E or 90° from N, therefore ship is traveling due East.

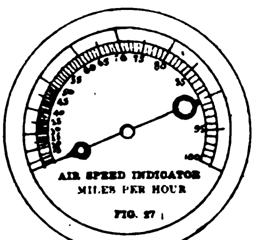

FIG. 27

FIG. 30

Air Speed Indicator indicates relative wind pressure. Instrument on dash is connected by copper tube to nozzle fig. 30) located forward with nozzle (c) pointing to direction of motion. The pressure of wind or air velocity, in miles per hour is thus indicated.

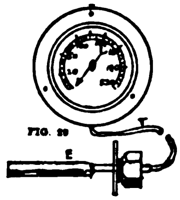

FIG. 29

Extension Thermometer: Indicates temperature of water or oil circulating through engine in degrees Fahrenheit. A similar device to fig. 9. page 188, but this instrument is placed on dash. Tube (E) contains ether, which is connected to circulating system of engine. Expansion of the ether causes needle to indicate temperature. See fig. 22, page 917.

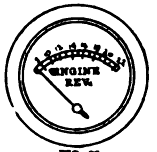

FIG. 26

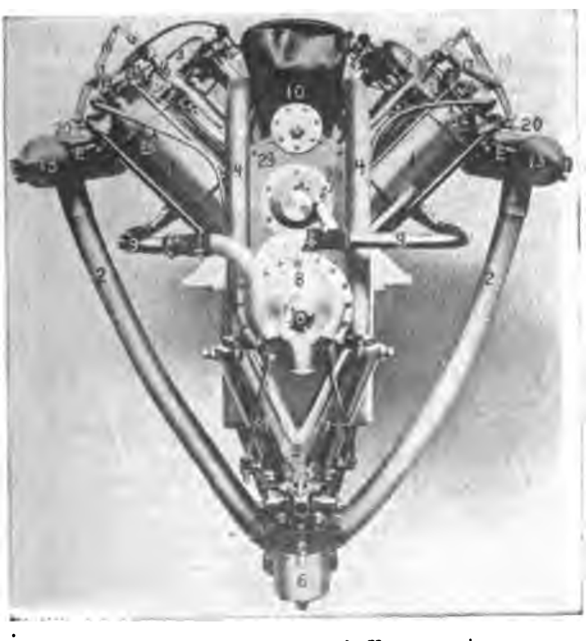
Tachometer is an instrument showing revolutions of engine crank and is connected with Curtiss engine at 28. 2 means 20, 10 means 1,000, 22 means 2,200 r. p. m., etc.



Rear view of Curtiss 8 cyl. V-type engine.

Curtiss Airplane Engines.

Model OX: Bore 4 in., stroke 5 in. 1400 r. p. m. developing 90 h. p. **Cylinders,** 8 V-type with cylinders 90° apart. **Valves** overhead, one intake, one exhaust operated by push rods and overhead rocker arms; **weight** with propeller hub, without oil or water, 390 lbs.; **carburetion,** Zenith, see page 182; **oiling,** force feed to all bearings; **cooling,** water, centrifugal pump; **ignition,** Berling high tension, 8 cylinder magneto, with two spark plugs per cylinder. **Valves** seat is machined direct in cylinder head in a similar manner as that shown in the Hall-Scott, page 912. In the Curtiss OX2 and Hall-Scott it is necessary to remove cylinder to remove valves. **Pistons,** aluminum alloy. **Inlet valves** are nickel steel and **exhaust,** tungsten steel. **Steel water jackets** brazed to cylinders. **Cylinders** are staggered and **connecting rods** are placed side by side.

Model OXX is the same, except ¼ inch larger bore than "OX" and is rated at 100 h. p. at 1400 r. p. m. Illustration shows the rear view of the OX and OXX engine.

Model V2: Bore 5 in., stroke 7 in.; 1400 r. p. m. developing 200 h. p. **Cylinders,** 8 V-type. Similar to OX except two high tension magnetos are used and two Zenith carburetors placed on the side. Weight is 690 lbs.

Twelve Cylinder: Bore 5 inch, stroke 7 in., h. p. 250 at 1,400 r.p.m. On some of the Curtiss engines, a thin aluminum liner is placed between crank case and cylinders for flying at altitudes below 6,000 feet, in order to give a lower compression which does not result in pre-ignition at low altitude. For high altitude work these liners are removed.

Name of Curtiss Parts.

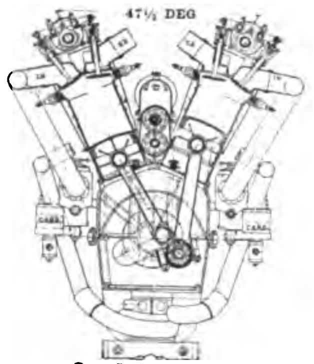
1, cylinders; 2, hot air pipes to carburetor air intake; 3, inlet manifold; 4, inlet pipes; 5, water jacketed inlet; 6, Zenith Duplex carburetor; 7, hot water pipes to inlet; 8, water pump; 9, water pipes; 10, *magneto; 13, hot air jacket surrounding exhaust manifold; 16, push rod; 17, inlet rocker arm; 18, exhaust rocker arm; 19, spark plug; 20, exhaust valve; 21, inlet valve; 28, tachometer connection; E, exhaust.

Under 1, on cylinder on right, is breather pipe. Oil pump is located below and in rear of water pump.

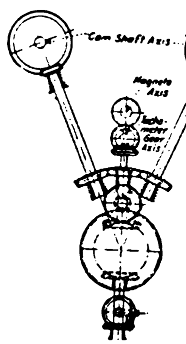
See page 918 for firing order of Curtiss engine.

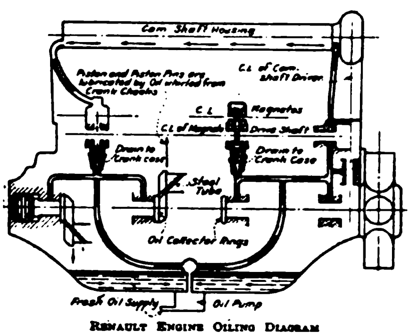
CHART NO. 418—Airplane Instruments. Curtiss Airplane Engines.

*The Berling D-81-X2, 8 cyl. high tension, single spark magneto was used on the Curtiss engine on the JN4 tra ing plane. Magneto armature revolves twice crankshaft speed. It is of the usual high tension magneto princi with distributor designed for 8 cylinders. See page 927.



CROSS-SECTION RENAULT TWELVE-CYLINDER ENGINE





RENAULT ENGINE OILING DIAGRAM

Renault Airplane Engine.

Is a 12 **cylinder V-type** with cylinders placed at angle of 47½°. **Bore** 125 mm., **stroke** 160 mm. **Cylinders** are steel and are almost a duplicate of the Mercedes, page 916.

Valves overhead type, operated by overhead camshaft. Two valves 2⅜ in. di. per cylinder. Valve port is 2 13/32 in., valve stems 7/16 in. di., valve seat is set at 45° and ⅛ in. thick. They open 15/32 in. **Pistons** cast iron, 3⅝ in. in length. There are eighteen 11/32 in. holes drilled in skirt. **Connecting rods** articulated type of I-beam section in which the shorter rod is attached to a boss on the master rod by a pin to form a hinge. **Crankshaft** carried in four babbitt lined bronze shells secured to ribbed-steel bearing caps. **Gearing system** is shown in center illustration. The inclined shafts operating at three times camshaft speed, driving camshafts through straight bevel gears. **Oiling system** is shown. Oil is carried through ducts through copper tubes up to and through overhead camshaft case and returns down through the distributing gearing case to oil sump. **Ignition** consists of 4 magnetos mounted on the same axis driven through spur gears.

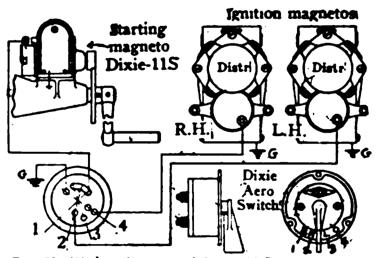


Fig. 23—Wiring diagram of Dixie 11-S starting magneto, with control switch and two service magnetos.

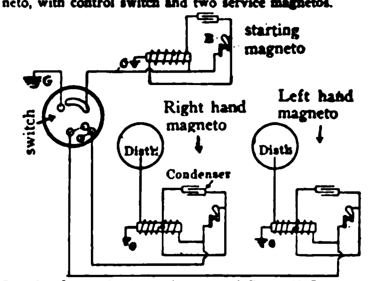

Fig. 24—Internal wiring diagram of Dixie 11-S starting magneto, control switch and two service magnetos

Magnetos for Airplane Engines.

In the 8 and 12 cylinder magnetos a field structure, rotor and cam are sometimes employed which produce four sparks per revolution of the magneto shaft, two of the sparks being of one polarity and two of opposite polarity.*

The speed at which magneto should be driven is as follows: Dixie magnetos will deliver one, two or four sparks per revolution of the drive shaft and when installed on four cycle engines, run as follows:

1 Cyl.	½	engine speed,	with 1 lobe cam.
2 Cyl.		engine speed,	with 1 lobe cam.
3 Cyl.	1½	engine speed,	with 1 lobe cam.
4 Cyl.		engine speed,	with 2 lobe cam.
6 Cyl.	1½	engine speed,	with 2 lobe cam.
8 Cyl.		engine speed,	with 4 lobe cam.
12 Cyl.	1½	engine speed,	with 4 lobe cam.

Therefore during two revolutions of crank shaft on an 8 cylinder engine 8 sparks would be produced, or 4 per rev. On a 12 cylinder engine, 12 sparks would be produced during 2 rev. of crank, as armature makes 3 rev. to 2 of crank and 4 sparks per rev. or 12 sparks per 3 rev.

****Where magnetos have separately driven distributors,** as per page 918, then a single contact (C) is on distributor of magneto (per fig. 14), which connects with separate distributor.

Double ignition or connection for two synchronized magnetos, is shown in figs. 23 and 24. Note switch position below (assuming that upper part of switch lever is connected with ground (G) instead of starting magneto):

Switch position 1, both magnetos generating; switch position 2, L. H. magneto short-circuited or off, R. H. generating; switch position 3, R. H. magneto short-circuited or off and L. H. generating; switch position 4, both magnetos off or short circuited.

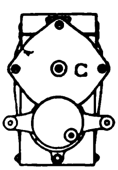

Fig. 14—Magneto

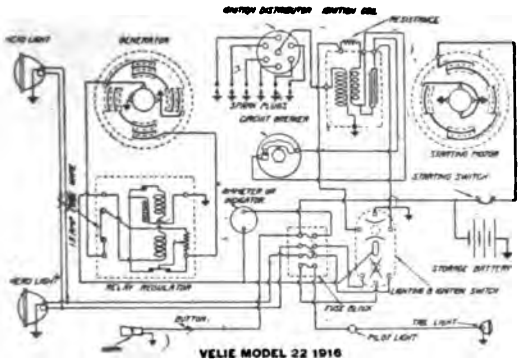
Dixie 11S starting magneto is an auxiliary source of current with which to operate the ignition on airplane engines, whereby a shower of sparks can be produced at slow cranking speeds. It carries a breaker (B) for interrupting the current which it supplies to one of the magnetos when starting. The starting magneto is operated by hand which drives it 4 times as fast as the regular running magnetos. As long as the platinum points of the ignition magnetos are closed, any connection with the starting magneto is ineffective, but as soon as the platinum points separate, the primary of the ignition magneto, which is connected to the starting magneto is then in series with the starting magneto, and a shower of sparks for ignition is produced, while the points remain separated.

The starting magneto is connected to the regular ignition magnetos as shown in figs. 23 and 24. There are four switch positions as follows: Switch position 2, left hand magneto is connected to starting magneto; switch position 3, right hand magneto is connected to starting magneto; switch position 1, both magnetos running, starting magneto disconnected; switch position 4, both magetos off or short circuited. The spark is produced from the ignition magnetos during the time the contact points are open, which is for a duration of about 27 degrees.

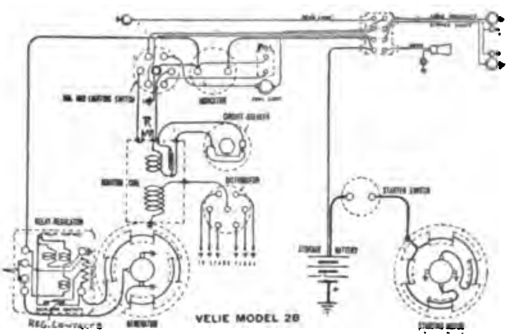
CHART NO. 414—Renault Airplane Engine. Splitdorf-Dixie Airplane Magnetos.

*The magnetos can also be of the unidirectional type, meaning that the spark is of one polarity only. There are four magnetic breaks within the magneto, but owing to the use of a cam of slightly different construction, only two sparks, both of the same polarity can be produced.

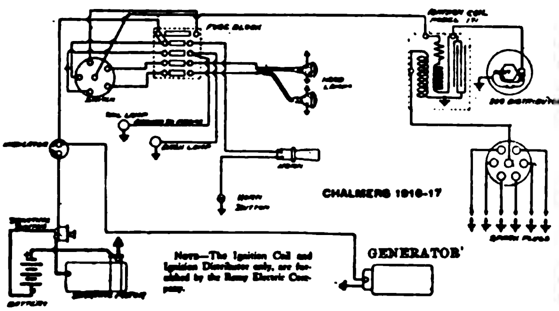
**See figs. 19 to 26, page 298, for distributors where a single magneto has 8 or 12 segments.



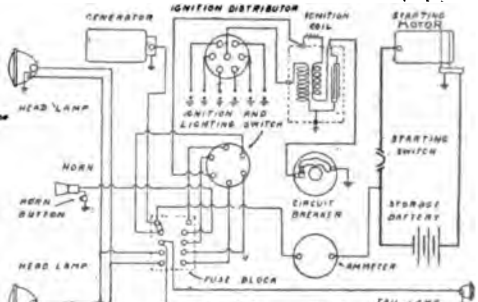
VELIE MODEL 22 1916



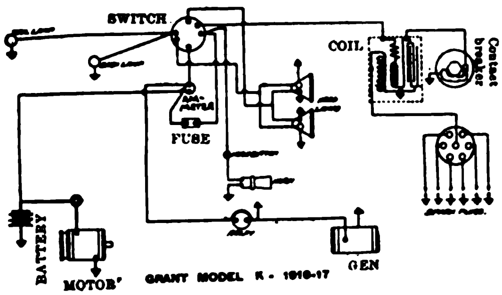
VELIE MODEL 28



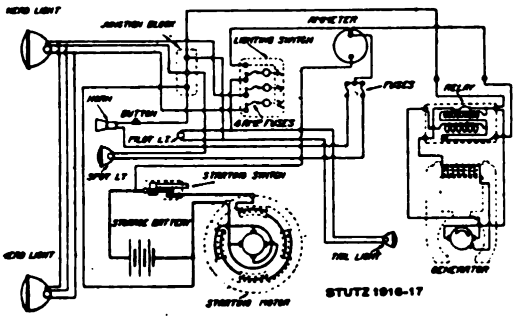
CHALMERS 1916-17



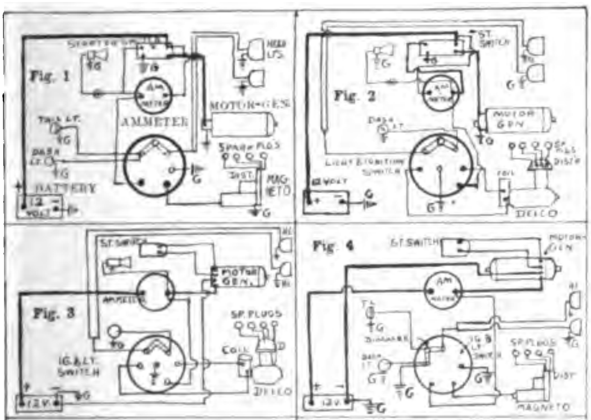
Chalmers 1918.



GRANT MODEL K - 1916-17



STUTZ 1916-17



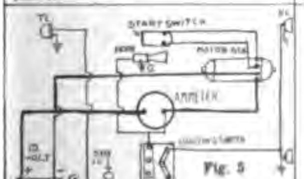


Fig. 1, Single-wire system using magneto ignition; Fig. 2, Single-wire, using Delco ignition; Fig. 3, Two-wire system for starting motor, rest grounded; Fig. 4, early 1916 system with magneto ignition; Fig 5, 1915 system, not showing ignition. North-East electric system is used. (G, means ground).

Dodge Electric Systems.

The North-East system on page 369 and 370 is the standard model "G" used on the Dodge since fall of 1916, with slight internal modifications. For ignition, the Dodge has used the high tension magneto, Delco system and since March, 1918, the N. E. model "O" system (fig. 7) has been used.

On the 1915 and early 1916 cars, the model D electric system (fig. 5) was used. With this system a cut-out and relay type of regulator were contained in the starter-generator unit (this can be determined when there are 4 terminals on starter-genrator, see fig. 6).

The model "G" system differs from all previous models in that it has a third-brush regulation instead of a current relay type regulator, which formed a part of all preceding N. E. models. The cut-out however is retained, but it is now enclosed in the housing with starting switch (pages 369 and 370), instead of in generator itself, therefore only one connection to starter generator and one grounded terminal.

Charging rate is 6 to 7 amperes at 16 m. p. h. up to 21. Over 21 the rate decreases as low as 8 amperes. Generator

—continued on page 924.

CHART NO. 415—Wiring Diagrams Remy Electric Systems. Dodge Electric Systems.

Instead of an ammeter, the Dodge system uses a charging or battery indicator, see page 370 and 410 for principle.

—continued from page 923.

output can be adjusted as low as 4 amperes at 1800 r. p. m. at 15 volts, or as high as 10 amperes at same voltage, by moving third-brush stud in rear of generator, per instructions on pages 733 and 369, 870.

Charging rate can be tested by inserting an ammeter between positive terminal of battery and cable attached thereto. Measured this way, it will be found to be from 1 to 2 amperes less than total generator output, even with lamps off, due to ignition consumption.

Actual output of generator can be measured with a 15 ampere ammeter inserted between No. 3 binding post (on illustration, page 870), and positive terminal of charging indicator.

Fuse is located on commutator end of starter-generator. It is the first place to look in case of failure of current supply—see page 733 and 870.

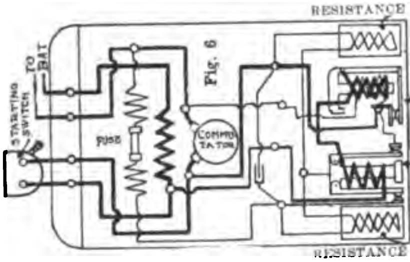

Fig. 6—Internal circuit of North-East Electric System on 1915 and early 1916 Dodge. Ignition and light circuits not shown.

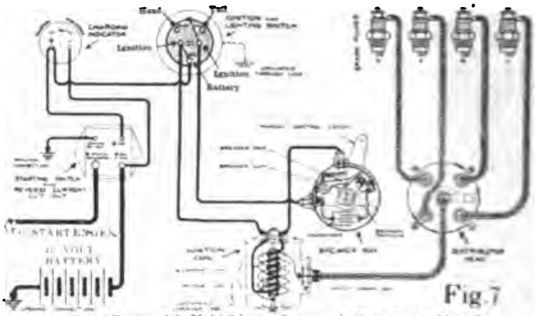
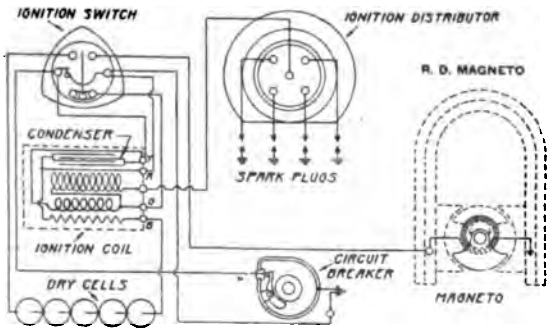
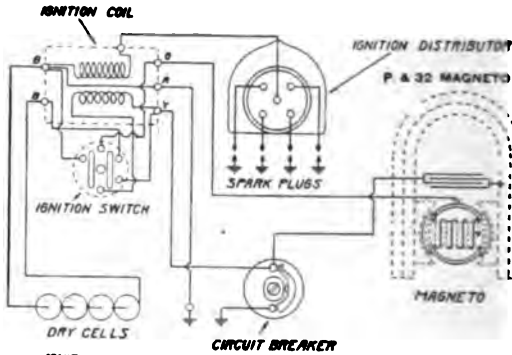
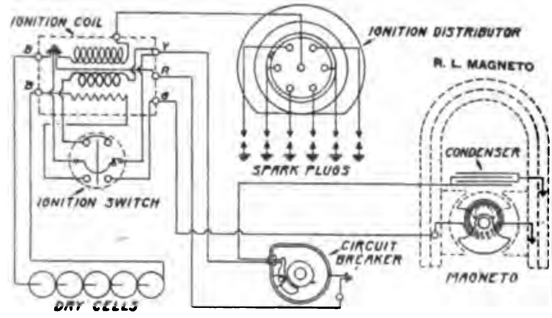
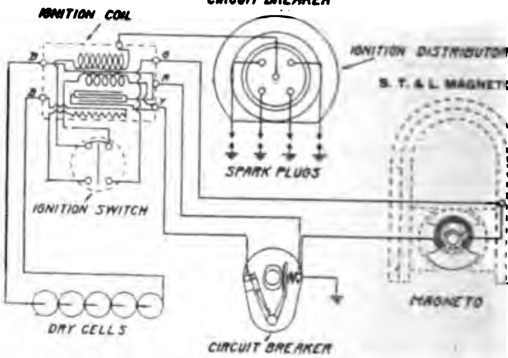


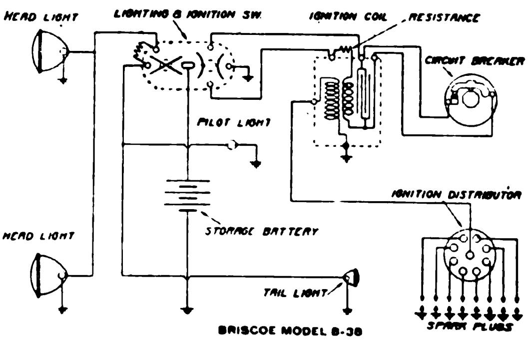
Circuit Diagram of the Model O Ignition System on the Dodge Brothers Motor Car











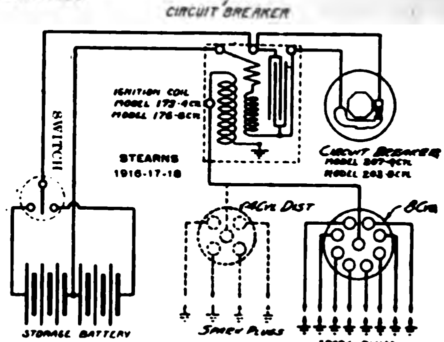


CHART NO. 416—Dodge Electric Systems—continued. **Remy Magneto and Wiring Diagrams.**

Bijur Constant Voltage Regulation Generator.

The voltage regulation system is shown in fig. 5. With this system the amount of current generated depends upon the state of charge of battery and the amount of lamp load in use. With a discharged battery the voltage is a minimum, but as the charge of battery proceeds the voltage of battery will increase, so that the difference in pressure between generator and battery is continually diminishing. If battery is fully charged, then generator charging current will be small. Therefore the charging current is variable and is independent of the speed, and tapers from maximum with a discharged battery to minimum with a fully charged battery.

After generator reaches a speed at which it develops its normal voltage, the voltage does not increase with speed, but remains constant.

Voltage regulation permits of a battery being charged at a high current rate when battery voltage is low and a much lower rate when battery voltage is high.

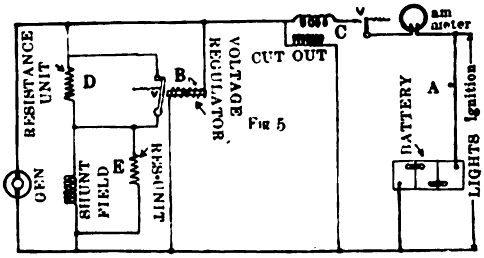

Fig 5

Operation of cut-out. (C. fig. 5): Its purpose is to connect and disconnect the generator to battery when generator is at rest or at very low speeds. It has a shunt and series winding as explained on pages 334, 342. The shunt winding is connected across the wires from the generator so as to receive the full voltage of generator and when machine attains speed at which it develops 6.5 volts, the shunt winding is sufficiently energized to close the cut-out armature (V). The series winding is connected in the main circuit and current flows through it and its pull reinforces the pull due to the shunt winding and firmly holds the cut-out armature (V) closed. When the speed of generator is decreased to a speed where it generates voltage lower than battery, then a momentary discharge from battery through the series winding demagnetizes the coil (C) and cut-out is opened.

The voltage regulating unit (B) fig. 5, has a single winding connected across the wires from the generator. It is opened and closed owing to amount of pressure developed by generator. Below 7.75 volts the resistance (D) is cut out of field circuit, path being around it through V, giving generator chance to build up. Above 7.75 volts, coil (B) pulls V to it, which throws **resistance (D)** into field circuit which automatically reduces the generation. While running, this regulator armature vibrates rapidly cutting the resistance into and out of field circuit by means of vibrator V. Thus the pressure never goes above 7.75 or lamps would burn out. (similar to system of regulation shown in fig. 9, page 342).

The other resistance unit (E) which is connected in parallel with field winding is to absorb the field energy when the regulator contacts are open and reduce sparking at contacts.

Ammeter: In this particular system the meter is connected between generator and battery which indicates generator output only and does not show a discharge when generator is at rest. On some cars the meter is connected at branch (A) and with generator in operation, meter will indicate output less the current consumed by lights and other devices.

Adjustments. A hole is provided on regulator box for adjusting voltage regulator and another for cut-out. Turning adjusting nut to right on cut-out **raises** the cut-in voltage. Turning adjusting nut on voltage regulator to right raises generator voltage.

Before adjusting cut-out disconnect one of battery terminals and place head light switch on. Voltmeter leads should be clipped to generator **brushes**, engine run slow, gradually increasing speed. Adjustment should then be made so cut-out will close at 6.5 volts, the voltage will then immediately drop on closing, which indicates it has closed.

In setting voltage regulator, connect generator to battery having specific gravity of 1,250 and light switch off. Voltage should be measured across brushes as above. Run engine at speed so generator will turn 1000 to 1400 r. p. m. and tension of spring regulated until 7.75 to 7.8 volts is generated. Set adjusting nut tight after adjusting.

Generator can be used without battery, if lights are on, otherwise resistance unit is liable to burn out if lights are not on and battery is removed.

Wiring: A single or double wire system can be used with this generator.

Care: (1) Every two weeks 2 or 3 drops of thin mineral oil should be put in oilers; (2) Every two weeks reverse regulator disconnect plug by pushing it in to unlock, then turn and reverse its connections; (3) Inspect brushes every 1000 miles, to see that they make good contact and move freely up and down. See pages 408, 409, 404, 406.

Bijur Constant Current Regulation Generator.

The system described above, used resistance (D) to weaken the shunt field circuit and is termed a "constant voltage" system of regulation of the output of current.

The "constant current" system uses a third brush to regulate the output, as shown in figures 6 and 7.

The "cut-out" is used with both the "voltage regulated" and the "constant current regulated" systems.

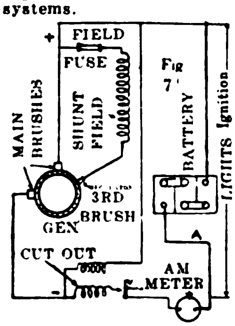

Fig 7

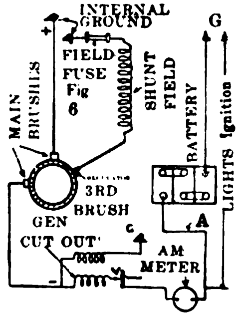

Fig 6

In fig. 6 and 7 the constant current regulated system is shown. The wiring can be a **two wire** system as per fig. 7, or a **single wire** system as per fig. 6.

With the constant current *third-brush regulation the generated current is independent of the voltage of the battery or the amount of lamp load connected, but depends upon the speed at which machine is driven and position of the regulating third-brush with respect to the two main brushes. The cut-out (V) closes when generator reaches 6.5 volts, or generator speed of 500 or 600 r. p. m. With increasing speed the current increases to maximum value, at speeds about 1000 to 1600 r. p. m.; at higher speeds current gradually decreases.

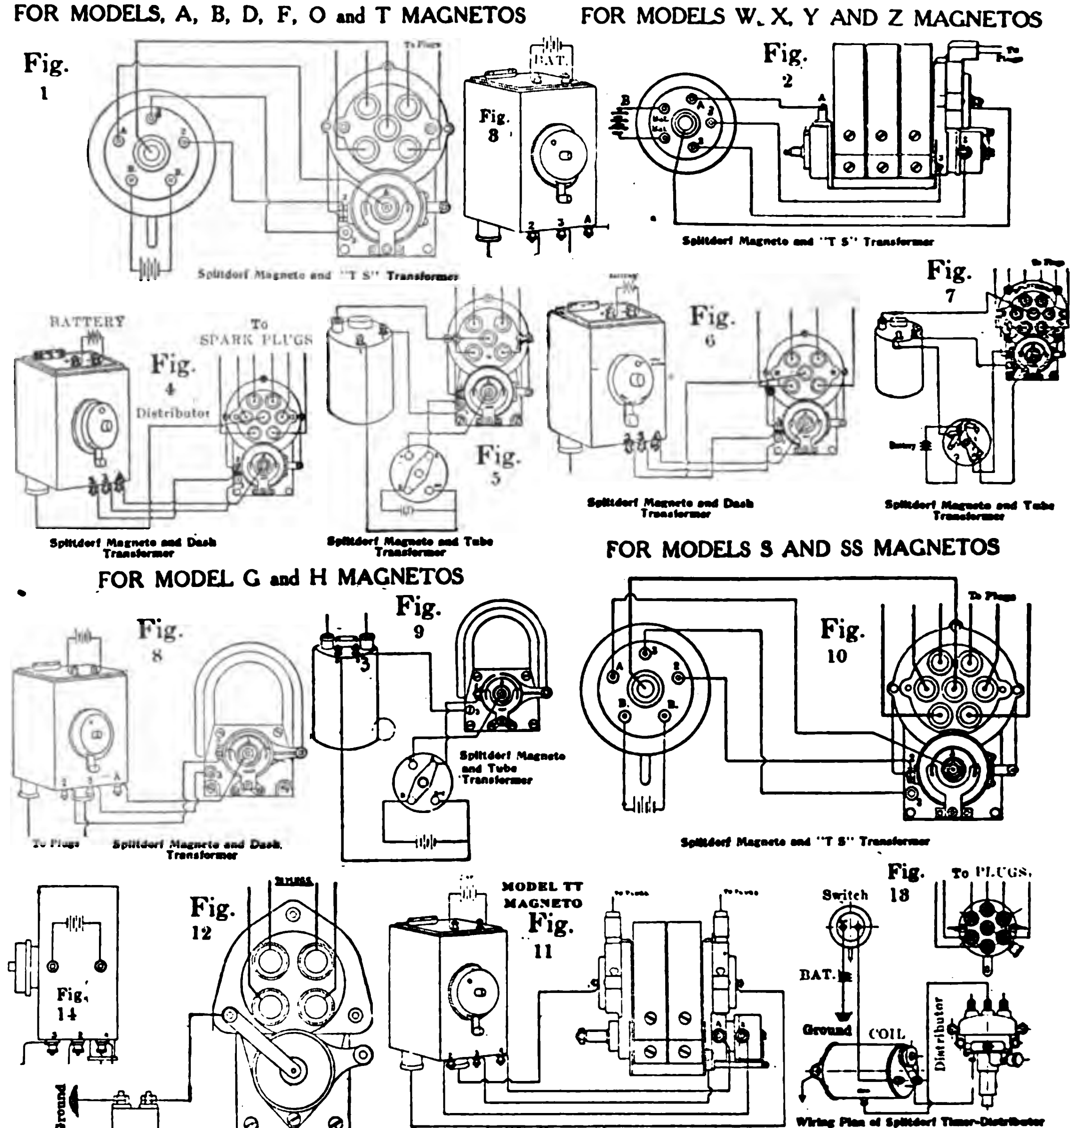
Adjustment: Moving the brush (by loosening nuts) in direction of rotation of armature increases generator output, in opposite direction, decreases. At 1400 to 1600 r. p. m. of generator (20 to 25 miles, car speed) the amperage should be not less than 12 or more than 15. Approximately a shift of third-brush 1/16" will change output 2 to 3 amperes. If adjusted on car, remove generator cables and tape ends, then place back after adjusting and run generator and test. Two or three trials may be necessary. Best results are obtained after running car when generator is hot and connected to battery with 1250 specific gravity (s. g.)

Fuse: A 6 to 12 ampere fuse is placed in field to protect coils burning out.

It is not feasible to supply current for lights from a constant current generator without a battery being connected in circuit, for instance, if lamps require 7 amperes and generator at speed, delivers 15 amperes, the generator voltage would rise until the additional 8 amperes not required by the lamps will be forced through the lamp circuit and burn them out.

Care of generator and starting motor—see pages 407 to 421. See p. 546 for cars using Bijur system.

CHART NO. 417—Constant Voltage and Constant Current Regulation—Bijur as Examples. See also pages 343, 345, 347. *See also page 389, explanation of third-brush principle.



Splitdorf Magneto Wiring Diagrams.

Many of the systems are similar. Note diagrams show both the dash type and tube type coils. For instance, fig. 3 is dash coil for models A, B, D, F, T, W, X, Y, Z magnetos, whereas figs. 1 and 2 show connections to the tube type coil. Many of the above ignition systems were used several years ago, but are shown as a reference for older model cars.

Magneto in fig. 1 and coil in fig. 14 would constitute the model O system. Magneto in fig. 2 and coil in fig. 3 would represent the model X system formerly used in the Maxwell "40." Fig. 12 is the EU4 magneto. See pages 290 to 298 for Splitdorf Dixie magneto and pages 228 for Splitdorf coil connections.

Berling Magneto.

Figs. 9 and 10 show the two-spark system. When switch is in position (1), primary winding is short circuited and magneto is "off." When on (2), magneto operates as a single spark magneto. When in this position (2), end of secondary is grounded and is position for starting, because at slow speeds all of intensity of magneto is concentrated to one spark plug instead of being divided. When on (3), which is running position at full speed, magneto supplies current for the two spark plugs in each cylinder and current is divided between the two. Breaker points are set .016 to .020 in.

Another two-spark system is shown on page 283.

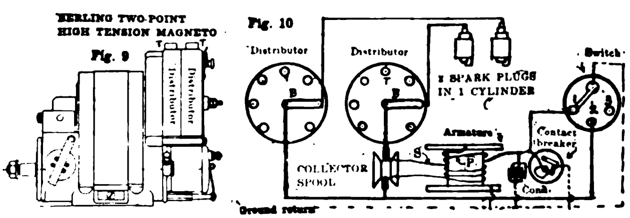


CHART NO. 418—Wiring Diagrams Splitdorf Magneto Systems. Berling Two-Spark Magneto.

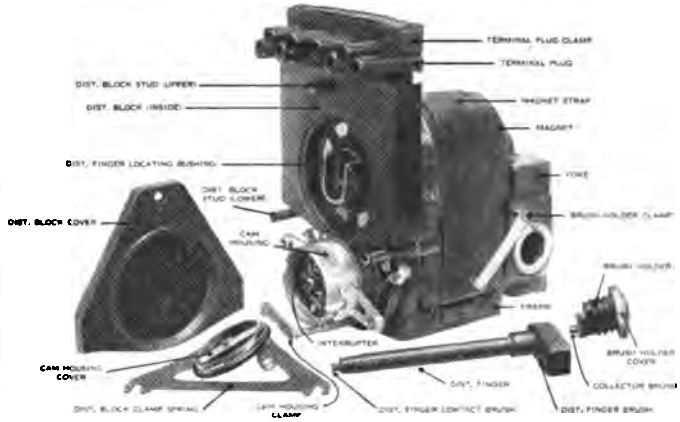
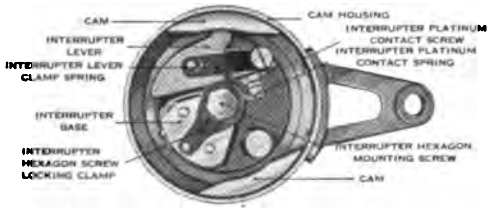
See page 864F for advertisement of a large Book of Wiring Diagrams in blue print form. This book also deals with Storage Batteries and Electric Systems—send for circulars.

Stromberg Model "L" Carburetor. Berling Magneto.

Fig. 1. Sectional view of Stromberg carburetor, type L, page 176. The only difference between the type L and M, page 176 is in the "economizer" action, or the lifting of the high speed needle valve (A) automatically. This needle valve (A) on type (M) is hand regulated.



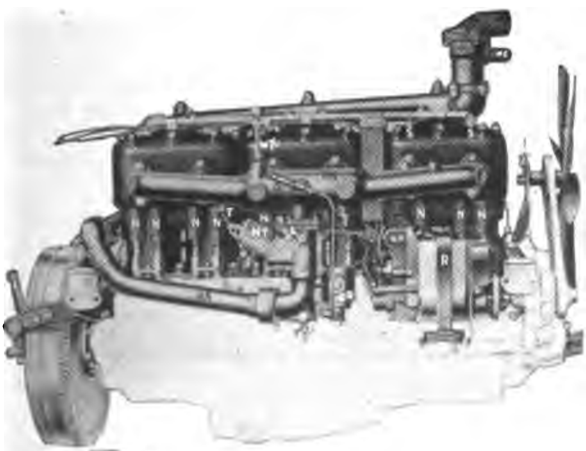


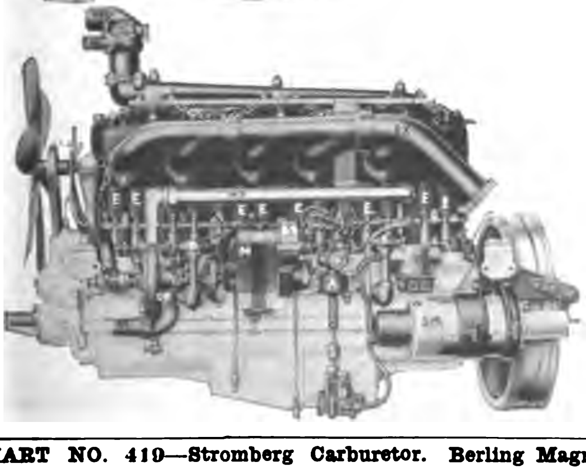
Berling type D-81x-2, high tension 8 cyl., single spark magneto as used on the Curtiss training planes.

The interrupter is shown to the left.

Pierce-Arrow "Dual" Valve Engine.

Dual valves, mean two inlet and two exhaust valves to each cylinder. The Stutz engine, page 109, uses dual valves but they are placed overhead instead of to the side as below. The White also uses a "T" head cylinder with two inlet and two exhaust valves per cylinder.





Advantages of dual valves is this: It is well known that greater power, especially at higher speeds is obtained by using large valves. For instance, in standard practice the rule is to have the valve diameter one-half that of the bore of cylinder. For a 4½ inch bore, a 2¼ inch valve is used. In order, however, to get the maximum possible power, a 3 in. valve with a ⅝ in. lift would give greater power, but to do this would result in noisy valves, due to the heavy valve spring required to close them promptly, and also on account of the tendency of the valve head to warp out of shape.

Therefore by using two smaller valves of 1½ in di., with a ⅜ in. lift, the same opening area as the single 3 inch valve is obtained. This gives the maximum power and a very quiet valve action, due to the use of light valve springs.

Name of Parts.

Pierce-Arrow: cylinders of 3 blocks, "T-head;" **valves** on side; **fuel** fed to carburetor by pressure; **ignition,** Bosch high tension magneto with a Westinghouse generator system as a reserve. The two systems are independent and connect with two sets of spark plugs. **WO,** water pipe from engine to radiator; **WC,** water bypass from thermostat; **WI,** water pump connection to radiator; **OP,** water pump; **WP,** water pipe; **S,** spark plugs; **N,** inlet valves; **HA,** hot air intake to carburetor; **CR,** carb. float chamber; **IM,** intake manifold (hot water jacketed); **B,** generator; **DR,** generator distributor; **G,** gasoline primer; **Y,** carburetor adjusting needle valve (controlled from seat); **E,** exhaust valves; **M,** magneto; **EX,** exhaust manifold; **BR,** oil filler; **O,** oil pump; **A,** oil pump drive gear case; **D,** electro magnetic starting switch for starting motor; **SM,** starting motor with automatic gear shift.

See page 277 for Pierce-Arrow ignition system.

*K-W Magnetos.

The K-W magneto differs from other magnetos in many ways, and possibly the clearest information that can be given, is by careful study of the diagrams and accompanying explanation.

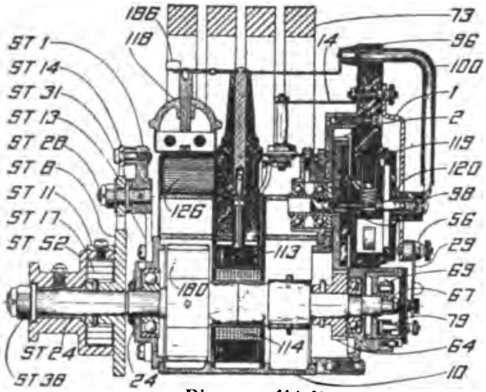


Diagram "A."

Diagram "A" shows a longitudinal sectional elevation of the model HK magneto. By referring to the numbers in the following description, a clear idea may be obtained of the function of the various parts.

1 Bridge or spider.	96 Distributor block.
2 Distributor gear.	98 Distributor brush holder.
10 Base.	100 High tension lead.
14 Low tension bus bar.	113 Secondary winding.
24 Dust cap or cover.	114 Primary winding.
29 Retainer spring.	118 Safety spark gap.
56 Switch binding post.	119 Secondary distributor brush.
64 Driving pinion.	120 Secondary contact plunger.
67 Cam.	126 Condenser.
69 Rocker arm roller shaft.	180 Rotor.
73 Magnets.	186 High tension bus bar.
79 Plunger for primary circuit.	

Illustration "B" shows the rotor (which is the only revolving part in the K-W magneto) and the complete assembled winding. The rotor is made up of soft Norway sheet iron stampings, which are riveted together and very accurately machined, as these rotor blocks,

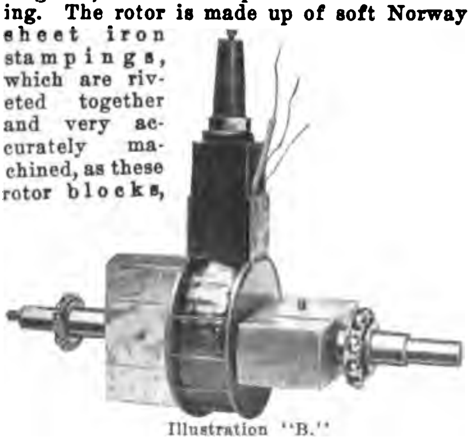

Illustration "B."

which run on high grade annular ball bearings, have only .003" space between their face and the face of the pole pieces. The rotor blocks are made in two halves and are held on the shaft by a taper pin and are mounted at right angles to each other.

In mounting the winding between these rotor blocks, the pin is taken out of one half, and the rotor block is withdrawn from the shaft to allow the winding to be placed in the center.

The winding: Complete assembled winding (illustration C) consists of a primary winding of heavy copper wire and a secondary winding (see also diagram A), which is made up of a great number of turns of very fine wire, these coils being wound circular in shape, assuring the largest number of turns with the least length of wire, which makes the most efficient type of coil. These windings are given an impregnation of high grade insulating compound by the vacuum process and the secondary winding is given 27 separate coats of varnish, each one baked twenty-four hours, which thoroughly insulates it from the primary winding and also assures it being as near water and oil proof as it is possible to make any high tension coil. These windings are assembled with the secondary outside of the primary and then enclosed in a brass housing with a hard rubber plug, through which the high voltage secondary is carried to the distributor brush of the magneto.

Illustration "C."

The condenser: No. 126, in diagram "A," is made up of a number of alternating sheets of tin foil and mica, every other sheet of tin foil being connected together, which makes two series of tin foil layers separated from each other by sheet mica. Each sheet of mica is tested separately before being used with 5000 volts for break down and after it is assembled it is given a test of five to six times the normal working voltage to which it is subjected, assuring reliability under adverse conditions.

The safety gap, No. 118, diagram "A," is a necessary part of any high tension magneto, its object being to form a path for the high tension current to jump across in case a secondary cable that leads to the spark plugs, should be off when the engine is running. This safety gap, as its name implies, prevents the winding from burning out, for as long as their is a path for the high tension current to pass through, it will never puncture the insulation of the secondary winding.

The magnetic field of the magneto is composed of four horse shoe magnets No. 73, in diagram "A," which are mounted on two cast iron pole-pieces, spaced 90 degrees apart. The rotor, No. 180, revolves within this magnetic field, and as the rotor blocks are spaced 90 degrees apart, there is a current wave four times to the revolution of the magneto.

*See also, pages 256, 296, 288 and 832 for additional information on K-W magnetos.

When the rotor is revolved within this magnetic field, the magnetic lines of force are cut or distorted and an electrical current is set up in the primary winding, which is carried up through part No. 14 to bridge No. 1, then through spring No. 69 to the circuit breaker cap and through the contact points in the circuit breaker back to the other side of the winding, completing the circuit.

When the current has reached its highest point, the circuit breaker-points are open and the change of the magnetic flux causes a high voltage to be set up in the fine wire secondary winding. This induction is assisted by the condenser, which is connected across the circuit breaker points, absorbing the spark which would occur if the condenser were not in circuit and also assisting by the discharge which takes place immediately after it is loaded.

The high tension current is carried up through the hard rubber plug to the bus bar No. 186, then through lead No. 100 to the distributing brush, which distributes it to the different segments on the distributor block, these segments being connected by high tension cables to the different spark plugs on the engine.

The distributor block is made of hard rubber into which is molded brass segments, one for each cylinder. The distributor brush which turns with the gear of the magneto is also molded of hard rubber and carries a carbon brush, which bears lightly on these segments as it passes, and the magneto is timed so that the circuit breaker points open and the high tension current is generated just at the instant this brush goes to the segment.

The K-W Circuit Breaker.

The entire circuit breaker is removable. Release spring No. 29 by pushing it aside. Pull out complete breaker box and remove cover nut No. 79. This allows removal of circuit breaker cap and gives access to breaker parts. The same type of circuit breaker is used on all K-W high tension magnetos, and is shown by diagram "D." It is arranged to have 30 degrees of advance or retard for regular work.

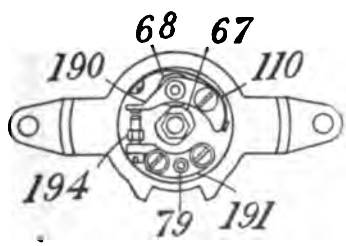

Diagram "D."

When the points fail to separate or when the distance is too far apart, adjust part 194 with small screw driver inserted through hole for that purpose in housing. The proper distance apart is $\frac{1}{64}$". A gauge is sent with every magneto. Spark plug $\frac{1}{64}$".

The firing point of the magneto is just when the points are beginning to open or break circuit, not when they touch.

To Open Distributor.

Remove the high tension lead No. 100, by turning it to right, which releases it at bottom. Unscrew nut at top of spider, and remove the bridge or spider No. 1, thus releasing cap on distributor block and giving view of distributor and brush No. 119.

*Impulse Starter.

Illustration "F" shows the impulse starter as applied to the model HK magneto and diagram "E" shows a sectional view of the impulse starter only.

Illustration "F."

The impulse starter consists of two separate members, one of which is called the ratchet and one the starter case. The ratchet is fastened directly to the rotor shaft of the magneto and the case connects to the coupling, which is fastened to the shaft that drives the magneto. Interposed between these two members is a clock spring which performs the function of driving the rotor when the starting mechanism is used.

When the engine is to be started, the trigger, ST-14 is pressed, which allows the hook dog ST-13 to drop into the notch on ratchet ST-6, so when the starter case ST-2

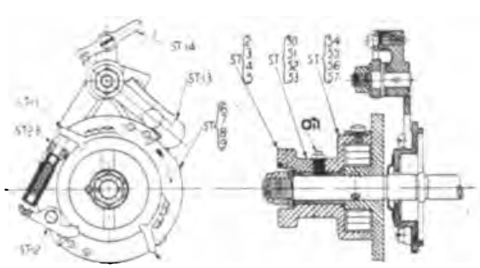

Diagram "E."

is turned by the drive shaft, the ratchet remains stationary, and the clock spring inside the case is wound up while the case is moving 80 degrees, which brings starter dog ST-11 around to the position where it moves the roller on ST-13, which in turn moves this hook ST-13 out of the notch on the ratchet.

When this hook dog releases the ratchet, it is given an impulse forward by the clock spring, and is thrown back to its original position, as shown in the diagram. While this rotor is being moved rapidly by this

*See also, page 832. Manufacturers of K-W Magnetos: K-W Ignition Co., Cleveland, Ohio.

spring, the circuit breaker points are open, causing the function of producing the spark.

The starter continues to operate until a predetermined speed has been reached, when the hook dog is thrown up and latched and the magneto is driven direct. The speed at which the starter throws out of engagement, is determined by the tension of the cushion spring on the hook dog.

To Time Magneto To The Engine.

First: Turn over crank shaft of engine, placing engine from 3° to 5° past top dead center on firing stroke.

Second: Mount and connect magneto so that the tripping mechanism will trip the impulse starting device.

Illustration "G."

Illustration "G" shows K-W high tension magneto, known as model TK, while diagram "J" shows a cross sectional view of this magneto. It will be noted that the principle of the model HK and TK magneto is exactly the same, the only difference being in the size of the magnetos and their appearance. The same principles of design and construction, are employed in both. Model TK, however, has flat magnets.

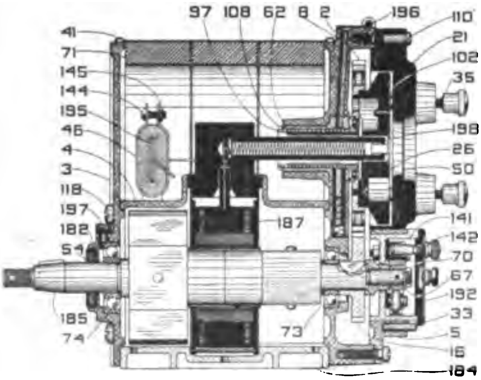

Diagram "J."

Both magnetos are of the inductor type construction, having a stationary winding and revolving rotor. This does away with all moving wires, collector rings, special contacts, etc. and is considered by the manufacturers the simplest form of construction.

K-W Low Tension Magnetos or Alternating Current Generators.

These generators are made for ignition, using a vibrating spark coil and low tension timer, and are made in several models, for either friction or belt drive.

They are also made for tractor and motor boat electric lighting systems, feeding the current direct to the lamps. **These generators will not charge a storage battery,** as they produce alternating current.

Internal Constructon.

This illustration "H" shows the internal construction and extreme simplicity of the K-W low tension magneto, designed on an entirely new principle, and patented by them. Instead of having wires wound

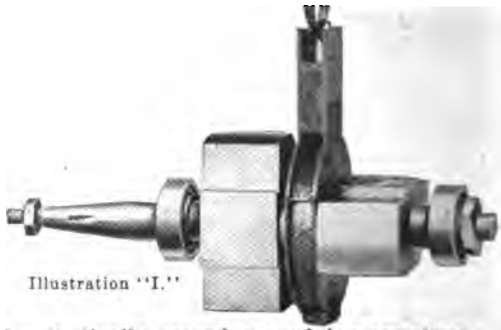

Illustration "I."

longitudinally around a revolving armature, it has stationary spiral winding of copper ribbon, as is shown in the center of illustration "I," and also in illustration "H," which is a view of the inside of a low tension magneto. The rotor changes the direc-

Illustration "H."

tion of magnetic flux through the winding, four times per revolution, and thus produces the electric current. This rotor revolves in two sets of high grade ball bearings and does not rub against or touch any other part on the entire magneto, as all other parts stand still. (See also, page 256.)

The terminals of the winding extend through the top of the pole pieces in which the rotor revolves and are securely connected to the binding posts, which are located at the end of the magneto.

The electrical part is housed in a case, making the magneto practically waterproof. It will stand any amount of spray or rain. Oil it occasionally, and the K-W generator will "stay on the job."

All models of K-W lighting magnetos or generators, in addition to having a special winding suitable for the lights, have the air gap between the rotor and pole pieces so adjusted as to make them automatically self-regulating, due to the impedance of the coil, to a very close degree, so as to take care of the various speeds of the engine.

Pointers on Adjustment of Dodge Drive System.

To Adjust Clutch.

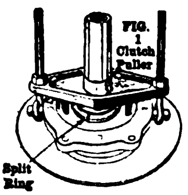
See page 666.

*Removal of Clutch and Gear Box.

1—Break universal joint; 2—drop emergency brake rod; 3—remove exhaust pipe completely; 4—block up engine at rear, just in front of the bell flywheel housing; 5—remove bolts in rear engine arms (47); 6—remove bolts holding bell housing flange (10) to crankcase; 7—drop foot brake rod; 8—disconnect flexible grease cup tube running from floor board to clutch throw-out; 9—slide unit to rear and lift out.

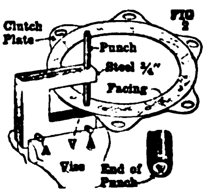
Disassembly of Clutch.

1—Remove two lock screws in clutch throw-out yoke (visible from clutch hand hole); 2—remove two nuts on clutch throw-out yoke; 3—remove clutch pedal (38) from its shaft and loosen brake pedal (39); 4—drive out clutch shaft (32) to the left; 5—lift out clutch unit; 6—apply clutch puller, fig. 1, to complete clutch disassembly. The puller consists of a cross member with a bolt terminating in a hook perpendicularly placed at each extremity. The hooks engage pins on the clutch; 7—draw down on puller nuts until the clutch spring is sufficiently compressed so that the split locking ring may be withdrawn; 8—remove split locking ring; 9—ease up on puller nuts, and then remove clutch spring; 10—clutch plates may now be taken apart.



To Replace Clutch.

See fig. 2. The facings come already cut and drilled so it is merely a matter of riveting a new facing in place on the driving discs 9, fig. A, page 931. A tool especially designed for this purpose is shown in fig. 2. The punch is made of a valve stem, hardened. In putting in the hollow rivets, half of them should face one way and alternate ones in opposite direction. This tool may also be used to rivet brake linings, page 689.



Noisy Rear Axle.

When there is a singing or humming noise constantly in rear axle, with the humming increasing with speed, and the rear axle mesh seems stiff when clutch is thrown out, it is usually due to the adjustment of the drive pinion (54) to the driven bevel gear (63) being meshed **too tight.**

When there is noise and back-lash, which is more noticeable when clutch is "thrown-out," and there seems to be a loose, jerky motion in rear, when clutch is "thrown-out," it is probably due to gears 54 and 63 **not meshing tight enough.**

Remedy: First see if there is oil on teeth of gears by taking filler plug out and sticking your finger on gear. Often times heavy grease will not throw all way 'round.

Adjustment: Ordinarily the adjustment of drive pinion (54) is sufficient. If not, then driven bevel gear (63) must also be adjusted.

Note. On other **makes of cars having "helical"** gears the same rules apply.

To Adjust Drive Pinion.

The whole drive shaft 52, fig. C, page 931, can be adjusted endwise to obtain exact position of the driving pinion (54) which is rigidly attached to it, in relation to the driven bevel gear (63) bolted to the differential. Two adjusting rings (67), fitted against the two Timken bearings (53), can be screwed forward or backward to obtain the proper position of the bevel driving pinion (54). These rings can be reached by removing the ring lock (71, fig. D). All that need be done is to back off one adjusting ring (67, fig. C), and screw the other one ahead, in whichever direction it is desired to move the bevel driving pinion (54). Be sure that each of them is holding its bearing rigidly before replacing lock (71).

Adjustment of Bevel Driven Gear.

To test if the bevel gear (63) is running quiet, jack up the rear axle and run the engine with the gears, in direct drive about 20 m. p. h. as indicated by speedometer.

After adjusting the bevel driving pinion (54) as explained above, if still noisy, then remove rear axle cover plate and the two adjusting ring lock screws (56) and readjust bevel driven gear (63) to the new position of pinion.

The large bevel driven gear (63) can be moved either to the right or to the left in order to insure its quiet engagement with driving pinion (54), by operating the two bearing adjusting rings (66, fig. C, page 931) in similar manner as those used in adjusting the drive pinion. After adjusting, they are locked in place by the adjusting ring lock screws, (56, fig. C and D, page 931).

Removal of Rear Axle Shafts.

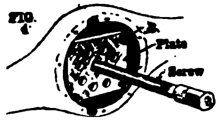
The rear axle is of the full floating type, permitting the removal of the drive shaft (58, figs. C and E, page 931), without jacking up the car.

To remove rear axle shafts (58) and flanges (82), simply unscrew the nuts on bolts 80, which hold the flanges to hub of wheel and remove them together with the axle shafts. If one axle shaft should stick, remove one on opposite side and drive or push other one out wth a long rod.

Lubrication of rear axle: use 5 pints, if empty, of gear lubricant, or enough to fill rear axle up to level of lower plug, 62, figs. C and D, page 931. If grease leaks out rear wheels, housing is too full.

To Disassemble Differential.

1—Remove axle shafts 58; 2—remove inspection plate; 3—take caps off bearings and lift out; 4—remove cotter pins and nuts on the 4 studs which hold differential unit together and disassemble.



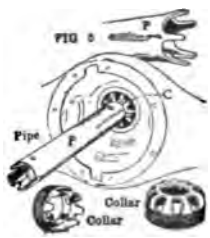


Fig. 4: To remove drive pinion (54), a plate is bolted to the 4 studs and pressure applied to shaft by screw.

Fig. 5: To remove front bearing adj. collar C, turn to left with a screw driver. A special wrench for this purpose can be made of a piece of pipe P.

Fig. 3: Puller for front of universal joint.

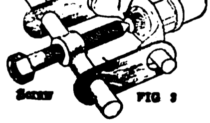

Fig. 6: Drag link cap is filed to give adjustment.

CHART NO. 421—Dodge Drive System—Continued.

LIBERTY ENGINE SUPPLEMENT.

Brief History.

At the declaration of war, Mr. H. E. Coffin, and soon thereafter, Mr. E. A. Deeds, were called upon to organize the production of aviation equipment.

J. G. Vincent, Chief Engineer of Packard Motor Car Co. and E. J. Hall of the Hall-Scott Co., of Berkeley, Calif., were called into conference at Washington, May, 1917. On May 29th, these two men started the design of an 8 cylinder aviation engine to develop approximately 200 h. p. and a 12 cylinder engine to develop 300 h. p. The first engine, an 8 cylinder was delivered to Bureau of Standards, Washington, July 4, 1917, and ran successfully.

The Engine Production Department, a portion of the Division of the Signal Corps was created in Aug., 1917, with Lieut. H. H. Emmons in charge as Chief Engineer of Engine Production Department.

The h. p. of 12 cyl. engine was increased to 440 h. p. and in spite of many difficulties, more than 15,000 engines were produced by Nov. 29, 1918, or within 18 months after work began. Certainly a marvelous accomplishment.

Oiling System.

The oil supply for the Liberty engine is carried in a reservoir which is cooled. This reservoir is mounted somewhere in the vicinity of the engine and from it oil is led to the connection on the right side of the oil pump body, which is marked "oil in."

There are two oil pumps; a delivery pump and an oil return pump.

Oil return pump: immediately above the oil delivery pump is located the "oil return pump" consisting of three gears, and driven by the same shaft as the delivery pump. The function of this oil return pump is to draw the excess oil out of the crank case and return it to the oil reservoir. One half of this pump draws oil from the oil sump at the propeller end of the crankcase and the other half draws oil from tho sump at the distributor end of crankcase. Both halves of the pump deliver oil to the connectien on the left side of the oil pump body marked "oil out," from which point it returns to the oil reservoir.

The oil delivery pump takes the oil and delivers it under pressure to a distributor pipe (C) running the entire length of the crankcase.

There is a pressure regulating valve between the pump and the distributing pipe which holds the pressure so that it does not exceed 50 lb. per sq. in.

The oil gauge pressure, after about 3 min. running at 600 to 800 r. p. m. should show about 5 lbs. pressure, and at 1600 r. p. m. up to 30 lbs.

From the distributor pipe, there are pipes (P) leading to the main crankshaft bushings. The crankshaft is hollow, and in the center of each main bearing there is a radial hole drilled through the shaft into the hollow center. A passage leads from each hollow main bearing to the adjacent crankpin, which is also hollow. A radial hole is drilled through each crankpin and carries the oil out on the surface of the pin.

There are oil grooves and passages in the connecting rod bushings to insure proper lubrication for both the forked and plain connecting rods.

The oil spray thrown off by centrifugal force from the ends of the connecting rods lubricate the **piston pins and cylinder walls.**

A part of the oil conducted to the crankshaft main bearing at the propeller end of the engine goes through a passage around this bearing and up through pipe leads F and E, to the propeller end of the camshaft housings. From the end of the camshaft housing it is led around the end of the camshaft bearing through a passage drilled diametrically through the bearing midway of its length.

Once every revolution of the camshaft, a hole drilled through the camshaft into its hollow center **registers** with the oil passage through the bearing.

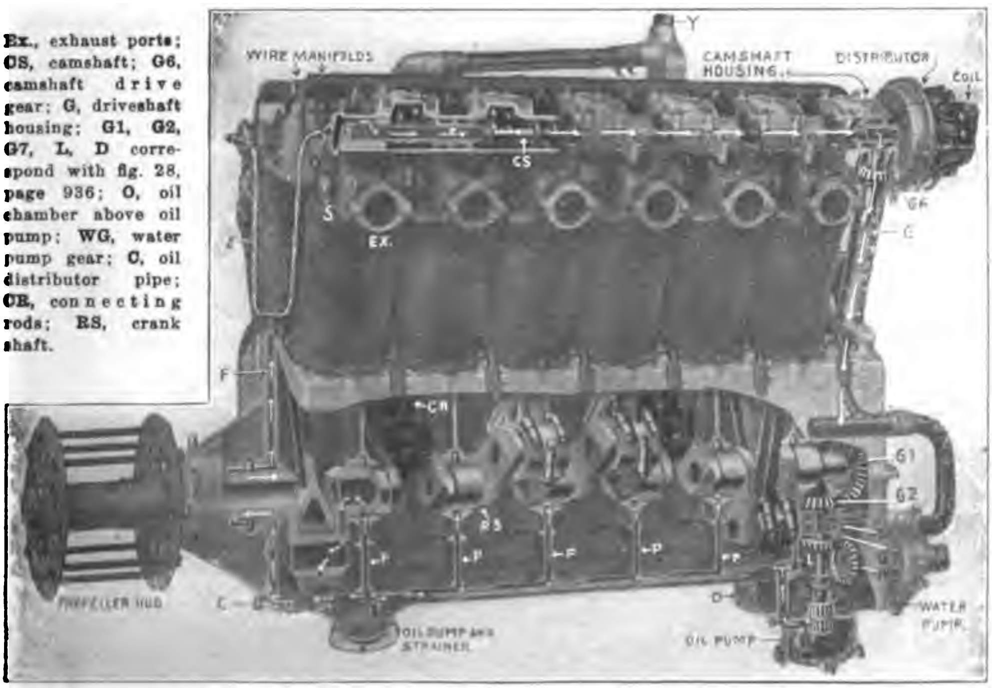
Thus once every revolution of the camshaft a small quantity of oil is forced into the hollow camshaft.

The oil is led through the camshaft and out through holes drilled in it to each camshaft bearing.

The excess works out of the ends of these bearings and collects in small reservoirs to a depth of about ¼ in. The cams, in revolving, dip into this oil and splash it over the cam rollers.

The excess oil eventually finds is way to the gear end of the camshaft housings, over the gears and down the drive shaft housing into oil chamber (O) just above the oil pump.

The excess oil thrown off in the crankcase by the connecting rods collects in this same chamber when the engine is inclined so that the propeller end is high. If the propeller end of the engine is low, this oil collects in the oil sump or chamber at the propeller end of the crankcase.



Ex., exhaust ports; **CS**, camshaft; **G6**, camshaft drive gear; **G**, driveshaft housing; **G1**, **G2**, **G7**, **L**, **D** correspond with fig. 28, page 936; **O**, oil chamber above oil pump; **WG**, water pump gear; **C**, oil distributor pipe; **CR**, connecting rods; **RS**, crank shaft.

General Construction.

The Liberty engine used in the De Haviland and other land planes and many seaplanes is a twelve-cylinder V-type with overhead valves and overhead camshaft. It **weighs** approximately 890 lbs., and the **horsepower** ranges between 350 and 400 in the Army type with the high compression pistons and 320 to 340 in the Navy type with low compression pistons (fig. 28).

The rated fuel consumption is 0.54 lb. a horsepower, or 36 gal. an hour with wide open throttle at 1700 r.p.m. Under service conditions about 30 gal. an hour is fairly representative consumption.

The oil consumption is 0.03 lb. a horsepower-hour, or 1½ gal. an hour with wide open throttle at 1700 r.p.m.

The horizontal flying speed of the engine is 1700 r.p.m., and the ground speed is 1600 to 1625 r.p.m.

Cylinders.

Cylinders: The design is followed after the practice used in the German Mercedes (page 916), **English** Rolls-Royce, French Lorraine-Deitrich, and Italian Fraschini, before the war and during the war.

The cylinders are made of drawn steel inner shells surrounded by pressed steel water jackets welded to the cylinders and at their own seam. Each cylinder has one inlet and one exhaust valve and two spark plugs.

Angle between cylinders: In the Liberty the included angle between the cylinders is 45°; in all other existing 12-cylinder engines it is 60°. This feature is new with the Liberty engine, and was adopted for the purpose of bringing each row of cylinders nearer the vertical and closer together, so as to save width and head resistance. By the narrow angle greater strength is given to the crank case and vibration is reduced.

A disadvantage of this angle, if used for automobile **work** would result in uneven firing impulses—which would be noticeable at low speeds, as the spark occurs close together, 22½°, and then far apart 37½° of distributor brush rotation, similar to explanation on page 918, except the Delco battery system is used on the Liberty instead of a magneto as explained on page 918.

With the airplane engine however, where the speed is usually high and constant, the uneven impulse is not noticeable.

The bore is 5 in. and stroke is 7 in., same as on the Hall-Scott, A-5 and A-7 engine, page 912, and as used on the Hall-Scott 12 cyl. engine. **Piston displacement** is 1649.34 cu. in.

An engine in all respects identical with the Liberty airplane engine, but having cast iron cylinders is used in Tanks.

Pistons.

The pistons are of aluminum, and are of the Hall-Scott design, page 913.

There are two designs of pistons used, one for the Army and one for the Navy. (see fig. 28, page 936.)

The Army-type pistons have a crowned head which gives an 18 per cent compression space.

****The Navy-type pistons** have a flat head which gives a 20.5% compression space.

The pistons are 5 in. long and have three rings of the eccentric type, all at the top of the piston. These piston rings are assembled with a gap between the ends of the rings not less than .025 in. The pistons of the engine weigh 3 lb. 3 oz.

Piston Pin

is a seamless steel tube, the tube being a drive fit into the bosses on the aluminum piston. Tube is 1¼-in. outside diameter and surrounded by a bronze bushing, upon which upper end of connecting rod bears.

Crankshaft.

The design follows the standard 12-cylinder practice, except as to oiling—see page 933 and below.

Crankshaft is a drop-forged seven-bearing crankshaft 2⅝ in. in diameter, the longer being at the propeller end.

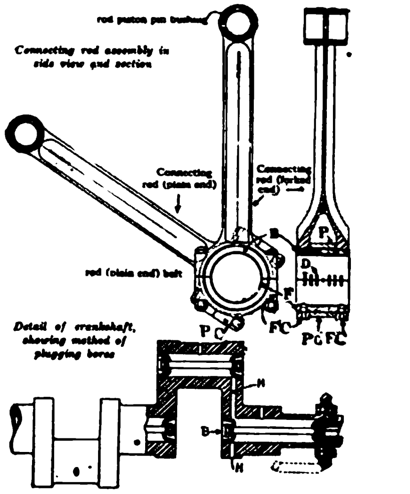
The shaft carries a propeller hub at its forward end and at the rear end carries a bevel gear for driving the valve mechanism.

A double row thrust bearing at the propeller hub end of the crankshaft takes the end thrust on the shaft.

The shaft is drilled for oil passage, the openings being drilled through the crank cheeks through the crankpins.

Connecting Rods.

The forked or straddle-type connecting rods of I-beam type are used. This type of connecting rod was first used by the French De Dion car and on the Cadillac in this country. The length is 12 inches between centers. Both crankshaft and connecting rods are made of chrome nickel steel.



Note, lower part of the plain end connecting rod is placed between the forks of the forked end rod. P—shows section of lower end of plain rod

—continued on page 985.

*Engines required for different classes of work were: (1) The Elementary Training Planes; (2) For Advanced Training Planes; (3) For Combat Planes. For 1, Curtis OX, 90 h. p. engine, page 921, and Hall-Scott A-7A, 100 h. p. engine, page 913 were used. For (2), the Gnome 110 h. p. engine, page 910, made by The General Vehicle Co., Long Island, N. Y. and the Le Rhone (similar), of 80 h. p., made by the Union Switch and Signal Co., Swissvale, Pa., and the Hispano-Suiza, 150 h. p., page 918, by the Wright-Martin Co., New Brunswick, N. J. For (3), the Liberty Engine. It was estimated that 22,500 would be required for the Army and Navy.

**See foot note, page 936.

over the bearing bushing E, which is the upper half of bearing bushing, and F. is the lower half. The plain rod has one cap (PC) and the forked rod, two caps (FC). The left rods are forked and the right, plain.

The clearance between crank pin and lower connecting rod bushing varies from .003 to .004". Clearance between plain rod and back of bushing .005".

The bushing carried by forked rod should have from .010" to .020" side play on the crank pin.

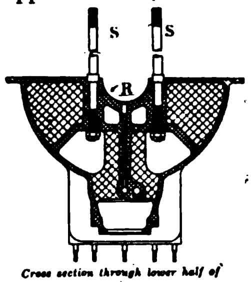
The plain end rod should have from .004" to .008" side play in the forked rod.

Crankcase.

The crankcase is in two pieces, both of which are aluminum castings.

The crankshaft bearings are on a line with the split in the crankcase, the lower halves of the crankshaft bearings being held in the lower half of the crankcase and the upper halves in the upper half of the crankcase.

The two halves are tied together by long bolts or studs (S), which pass through the upper half of crankcase, through bosses, the nuts being at the top of the upper half of the case. This gives an accessible construction which is at the same time rigid.



Cross section through lower half of crankcase.

A careful joint is made between the two halves of the crankcase in order to secure the desired alignment at the main bearings, the joint being lapped.

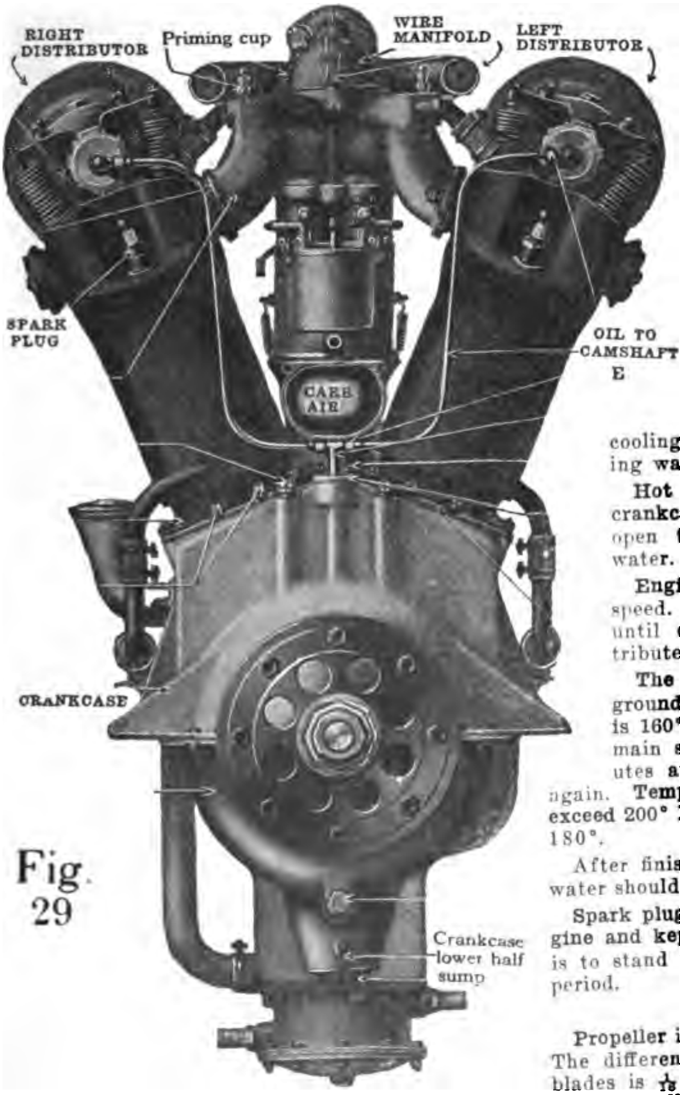


Fig. 29

Propeller end view of Liberty "12" Engine.

Cooling System.

Cooling water is circulated through the Liberty engine by a centrifugal pump running at one and a half times engine speed. **The capacity of this pump** is 100 gal. a minute at 1700 r.p.m. The cooling system from the pump inlet to and including the water outlet header will hold 5½ gal. of water or 46 pounds.

Cold Weather Instructions.

Anti-freezing preparations are not used. The cooling system is filled with boiling water.

Hot lubricating oil is put into crankcase. Oil can be heated in an open top container set in boiling water.

Engine is primed to start, at slow speed. Engine is then run on ground until oil has been thoroughly distributed.

The plane is not taken from the ground until the water temperature is 160° Fah. Engine should not remain stationary more than 10 minutes at a time, as it will get cold again. **Temperature of water should not exceed 200° Fah.** and should average about 180°.

After finishing a test flight, all oil and water should be drained before engine cools.

Spark plugs should be removed from engine and kept in a warm place, if engine is to stand idle over night or for a long period.

Propeller.

Propeller is 9 feet di.; blade 9 in. width. The difference in pitch between the two blades is 1/8 inch in 9 inches. The Hall-Scott propeller hub, page 915 was adopted.

Valves and Camshafts.

Valves.

The valves are mounted in the heads of the cylinders and are inclined at an angle of 15 deg. to the center line of the cylinder, so that the angle made by the center lines of the two halves is 30 deg.

The valves are the standard mushroom type with 45-deg. seat. The cylinder heads are bushed for the valves and the valve springs are of the double concentric type.

The intake manifold passes between the two rows of cylinders, and the carbureters in most of the installations are mounted in the V.

The entire valve drive is housed above the cylinders and can be readily removed without tearing down the engine.

The valves are operated from the camshaft by roller cam followers, which actuate the rocker shaft and in turn the valve rocker arm or lever. See page 938, fig. 67, also pages 914, 913, 912 which is a similar principle.

To adjust valve clearance; turn tappet screw, see fig. 67, page 938.

Cam-Shaft Drive.

The camshaft drive was copied almost entirely from the Hall-Scott motor, **page 914.** In fact, several of the **gears** used in the **first** sample engines were supplied by the **Hall-Scott Motor Car Company.** This type of drive is used by **Mercedes, Hispano - Suiza,** and others.

By referring to **fig.** 28, the drive system **can** be seen.

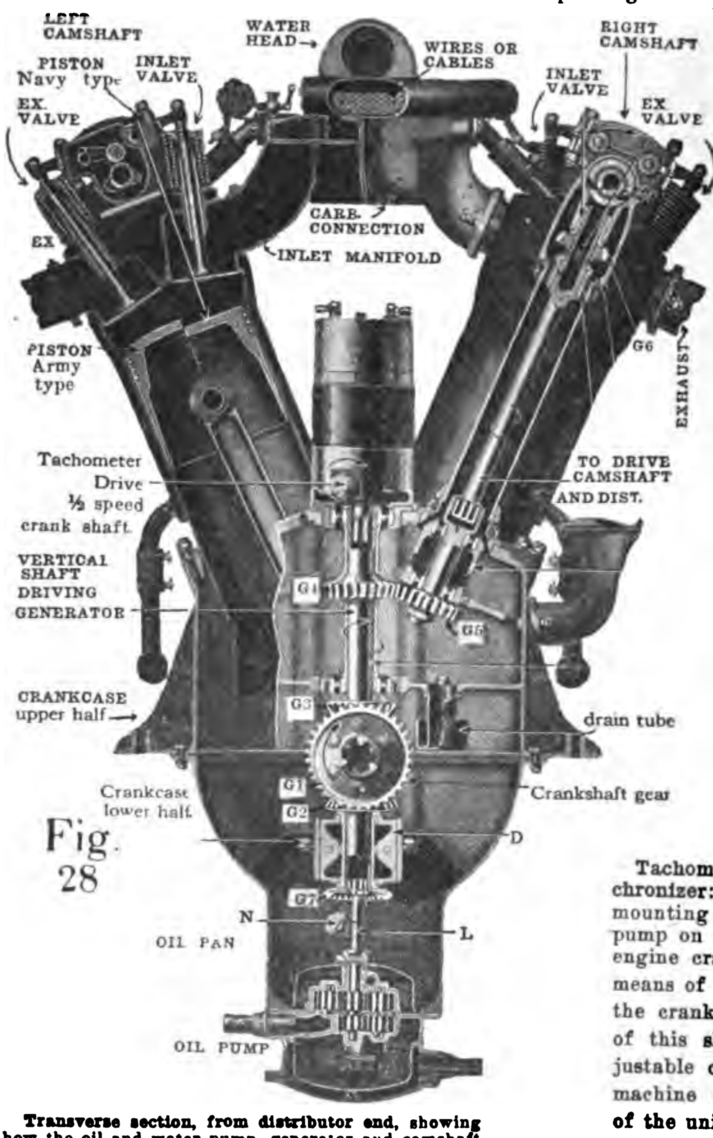

Fig. 28

Transverse section, from distributor end, showing how the oil and water pump, generator and camshaft are driven, and valve action.

Drive-Gear System.

G1, main drive gear on end of crankshaft; **G2,** drive gear for lower oil and water pump shaft; **D,** bearing assembly; **G7,** drive gear for water pump; **N,** oil plug; **L,** oil pump shaft (runs 1½ times engine speed); **G3,** driven gear for upper shaft; **G4,** drive gear for the two inclined shafts (through G5), which drives the right and left overhead camshaft.

The **inclined shafts** revolve 1½ times engine speed; **G6,** gear (one on each inclined shaft) to drive camshaft; **camshaft** revolves ½ engine speed; **distributor rotor** or brush, is driven from camshaft, at camshaft speed.

Tachometer drive and gun synchronizer: Provision is made for mounting a mechanically driven air pump on the distributor end of the engine crankcase and driving it by means of a splined shaft fitting into the crankshaft gear. An extension of this shaft carries a double adjustable cam designed to operate a machine gun. The over-all length of the unit is 6 in. **The tachometer** is driven from generator shaft.

CHART NO. 421—Valves, Camshafts and Drive Gear System.

The Navy type usually works at low altitudes and Army type at high altitudes, hence reason for low and **high compression pistons.**

Valve Pointers.

One method for testing gas tightness of a valve: This can best be done by inverting the cylinder with the valves in place and pouring a small quantity of gasoline in the cylinder. Watch for seepage around the valve. If the valves show any leak, they should be carefully ground in. The cylinder, for this operation, should be held in position by means of the flange at the bottom.

Valves should not be ground any oftener than is absolutely necessary; and then only enough to "clean up" the seat. If a valve is pitted or warped to such an extent that it is necessary to grind it heavily, care should be taken that any ridge or shoulder formed on the edge of the valve seat be dressed down with a fine mill file. The abrasive should be carefully washed off the valve, the seat and the inside of the cylinder. Test seating of valve with Prussian blue.

The exhaust valve spring exerts a pressure of 45 lbs. when compressed to a length of 2¼ in. The intake valve spring exerts a pressure of 23½ lbs. when compressed to a length of 2¼ in.

Piston Pointers.

Examine piston for scores. It is very likely that the pistons will show scratches which were caused during the first run in of the engine. It is difficult to draw a line of distinction between what is termed a scratch and a score. A piston should not be discarded unless the scores extend past the piston rings and seem to be of recent origin.

Examine piston for even bearing on its outside surface. If any piston shows excessive wear on one side at the bottom and not at the top, it is an indication that the connecting rod is twisted or bent. This rod should be straightened up before assembling.

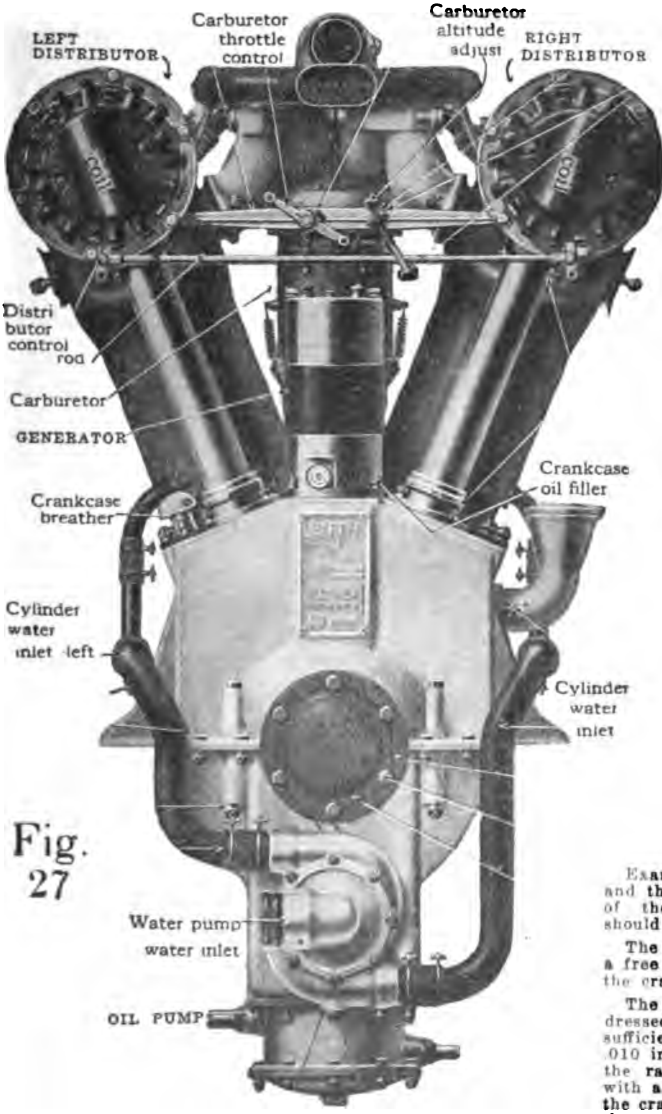

Fig. 27

Distributor or rear end view of Liberty "12" engine. Note—the high tension ignition coils are an integral unit of each distributor, being placed on the front of same. Note all controls are at this end of engine.

Piston Rings.

Examine piston rings for even bearing on the outside surfaces. The ring should be a free fit in the grooves and should not be so loose that any shake is noticeable.

Inspect condition of ring grooves through the ring gap as to carbon deposit. If the carbon is soft and not of great amount it may be wiped out with a soft rag over a splinter of wood inserted through the gap in the ring. If the amount of carbon is excessive and caked hard, the ring should be taken off.

Ring grooves should be wiped out with a soft cloth moistened with gasoline, and any carbon caked in these grooves may be scraped out with a piece of wood.

It is preferable to put back the old rings if the wear has not been too excessive, than to fit new rings which have not been run in.

The gap between the ends of the ring should not be less than .025 in. when the ring is fitted in the cylinder.

Connecting Rod Bearings.

If the bearing has been damaged or shows wear to such an extent that it is advisable to replace it, the new bushings should first be fitted in the forked end rod. Be sure that the bushing seats properly in the rod and that the dowel does not hold it away at any point.

The caps of the forked end rod should be put in place and drawn up tightly.

Examine the joints between the cap and the rod and between the two halves of the bushings. Caps and bushings should bear equally hard at the joints.

The **bushing should then be scraped to** a free fit .003 in. to .004 in. larger than the crank-pin.

The **ends of the bushing** should be dressed off with a fine mill file and a sufficient amount removed to permit from .010 in. to .020 in. side play. Touch up the radius at each end of the bushing with a scraper until it clears the fillet of the crank pin. Test this point by coating the crank pin and each fillet lightly with red lead or Prussian blue.

After fifty hours running, engine should undergo a thorough inspection.

CHART NO. 422—Distributor End, Showing Distributors, Generator, Water and Oil Pump. Practical Pointers.

Firing Order and Valve Timing.

DIAGRAM SHOWING FIRING ORDER

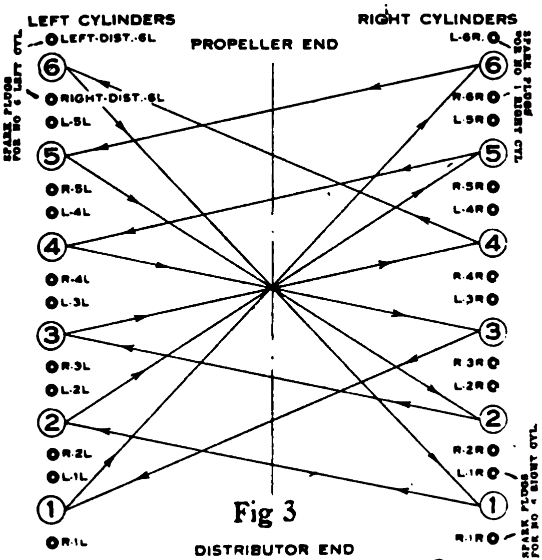

Fig 3

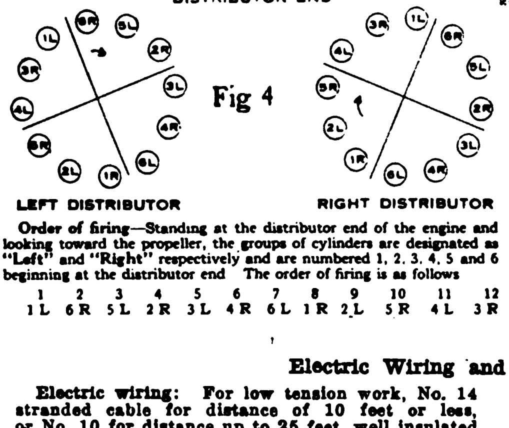

Fig 4

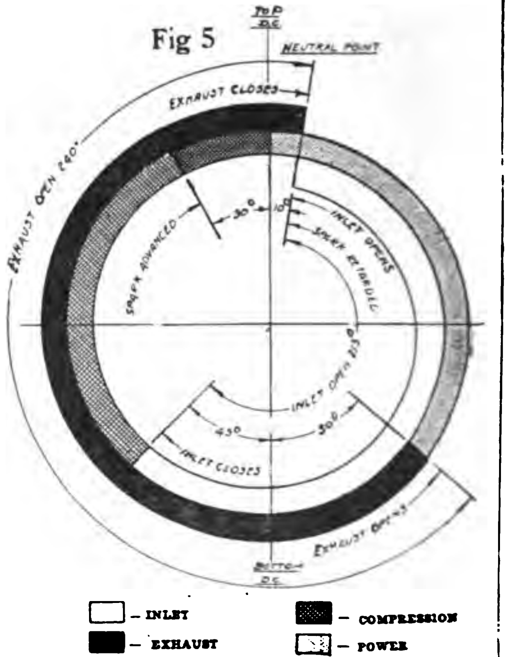

Fig 5

Order of firing—Standing at the distributor end of the engine and looking toward the propeller, the groups of cylinders are designated as "Left" and "Right" respectively and are numbered 1, 2, 3, 4, 5 and 6 beginning at the distributor end. The order of firing is as follows

1	2	3	4	5	6	7	8	9	10	11	12
1L	6R	5L	2R	3L	4R	6L	1R	2L	5R	4L	3R

Valve timing: Inlet opens 10° after top d. c. closes 45° after bottom d. c., exhaust opens 50° before bottom and closes 10° after top. **Note if spark is full advanced the spark will occur 30° before top d. c., on compression stroke.**

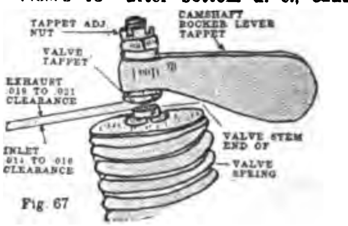

Fig 67

Electric Wiring and Ignition System.

Electric wiring: For low tension work, No. 14 stranded cable for distance of 10 feet or less, or No. 10 for distance up to 25 feet, well insulated with rubber and braid. Wires taped and shellaced where clipped to fuselage. See fig. 7, wiring diagram. **Single wire grounded return** (G), system is used.

Spark control advance and retard at distributor is, 10 degrees after dead center "retarded," and 30 degrees before dead center "advanced," see fig. 5, above.

Contact breaker (timer) gap when breaker is wide open, should be .010 to .013 of an inch.

Spark plug gap; .015 to .018 of an inch. Defects in all spark plugs are most apparent when the plugs are hot.

Timing: When engine is set on firing point of No. 1L cylinder, in other words, with No. 1L crank set 10 degrees past top of "compression" dead center, the carbon brush in the end of the distributor rotor should bear on the brass contact marked 1L on distributor head.

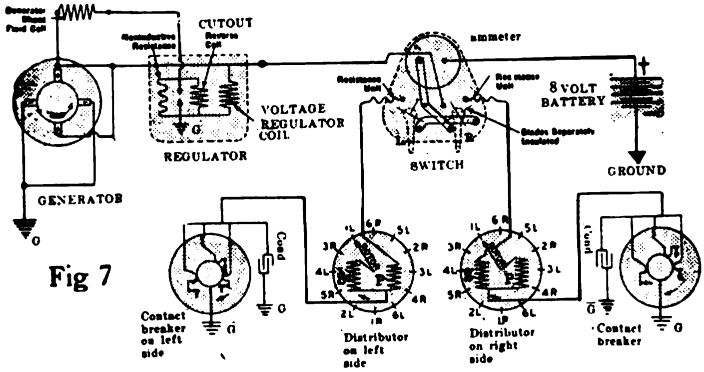

Fig 7

Fig 8 Switch

CHART NO. 423—Firing Order; Valve Timing. Electric System.

Electric System.

Ignition.

The ignition system (Delco) used on the Liberty twelve is the battery type with two independent breaker and distributor mechanisms, mounted on the ends of the camshafts, identical in every respect and each one firing all twelve cylinders.

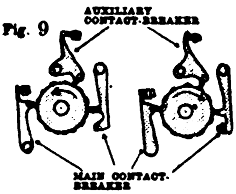
These distributors are supplied with electrical energy from two sources: For starting and idling speeds up to 650 r.p.m. current is drawn from the specially constructed **four-cell storage battery** which has sufficient capacity to ignite the engine at full speed for 3 hr. and is so constructed that it will function properly upside down. (8 volt, 11 ampere-hour capacity).

The generator builds up so that it takes up the load at 650 r.p.m.

Two main contact-breakers connected in parallel are located in each distributor box and the two circuit breakers are timed to operate simultaneously. The two contact-breakers are provided in duplicate as a precautionary measure. **The breaker cams** have 12 lobes.

Auxiliary circuit or contact-breaker is to prevent the production of a spark when the engine is turned backward or "rocked." This auxiliary breaker figs. 9 and 7, is connected in parallel with the other two through a resistance unit which reduces the amount of current flowing through it. The breaker is so timed that it opens slightly before the other two when the engine is turned in a forward direction. The opening of the main breakers then results in the production of a spark.

Fig. 9



When the engine is turned in a **backward** direction the two main breakers open first and no spark is produced due to the fact that the current continues to flow through the coil through the auxiliary breaker but in diminished quantity due to the resistance unit. By the time the circuit is opened at the auxiliary breaker the intensity of the magnetic field of the coil has weakened to such an extent that no spark is produced.

A coil is incorporated in the cover of each distributor head—see fig. 27, page 937.

Generator.

In addition to the battery, a positively driven generator, mounted to rear of engine, figs. 27 and 28, is provided, so geared that it runs at 1½ times crankshaft speed. It is a 4 pole shunt wound machine.

As stated above, electrical energy for starting and idling speeds is supplied by the battery. As the engine speed is increased, the generator "builds up" and its output grows greater until, at about 650 r.p.m. the generator voltage equals that of the battery.

The maximum generator output exceeds the requirements for ignition so that, at speeds above 650 r.p.m. the direction of flow of current is reversed and the excess output of the generator goes to recharge the battery.

Regulation: The generator is controlled by a "voltage regulator," mounted on cowl of plane, and consists of an iron core on which are wound three coils, the connections of which are shown in fig. 7. The regulator prevents the output exceeding a pre-determined figure. In view of this fact, the generator will supply **current for ignition** indefinitely, without the battery, so long as the engine speed is not allowed to drop below 500 r.p.m. It is not possible to crank the engine fast enough to start it on the generator, however.

Switch.

A duplex ignition switch, mounted on the cowl of plane, fig. 8, is provided which will permit either one or both distributors being turned "on." This switch is so constructed that either set of ignition alone can be used without connecting in the generator.

In **starting**, only one side should be used as, with both switches "on," the generator is connected to the battery. Under these conditions the discharge from the battery through the generator before the engine is started would be an excessive drain on the battery. It is essential that both switches be "on" at all **flying speeds.**

When operating at a speed under 650 r. p. m., only one switch should be used, as with both switches on. the generator is in the line and working as a motor. Result is, with both switches on, the pull on battery is about 12 amperes. With one switch on. the draw is 4 amperes, which is the ignition load.

Idling at 650 r. p. m. for an hour, with both switches on will discharge battery.

The ignition switch has an ammeter incorporated in it and this ammeter should be watched occasionally as it indicates the amount of current flowing to or from the storage battery.

If the ammeter shows a discharge at any speed above 650 to 700 r.p.m. with both switches "on" it is an indication that something is wrong with the generator circuit and that all electrical energy is being supplied by the storage battery.

If the ammeter stands at zero under the same conditions, it indicates that the storage battery is not receiving a charge, but that the ignition is being carried by the generator.

There are two ignition resistance units mounted on the back of the ignition switch, see fig. 7. They are for the purpose explained on page 878.

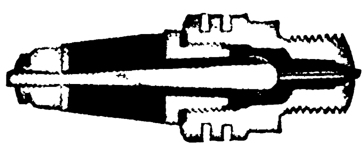
Storage Battery.

Storage battery is charged at .7 amperes for 70 hours if discharged. It is an 8 volt 4 cell battery.

Spark Plug.

There are two spark plugs per cylinder to the Liberty 12.

One airplane type of spark plug (Splitdorf) is illustrated below



They are subjected to pressure of 90-110 lbs. The gap distance is .015 to .018. The life of a plug of this type is 25 to 100 hours.

The parts of the Splitdorf plug is as follows; brass terminal, mica washers. lateral wound mica. steel center rod, 98% pure nickel electrode point, carbon steel from brass terminal to electrode and carbon steel shell.

The AC Titan, one-piece porcelain spark plug is used on the Liberty 12-cylinder engine.

Carburetion.

Two Zenith duplex carburetors, similar to principle explained on page 182 and 181, are used. This is equivalent to four single carburetors, each one supplying three cylinders of the engine.

Each duplex carburetor consists of a single float chamber and a single air inlet joined to two separate and distinct spray nozzles, venturi and idling devices.

Each of the two barrels of each carburetor is fitted with a throttle valve of the butterfly type. The two pairs of throttles are operated simultaneously by a shaft, provided with an adjustment at each end by which the pairs may be synchronized.

Each duplex carburetor is fitted with an altitude adjustment.

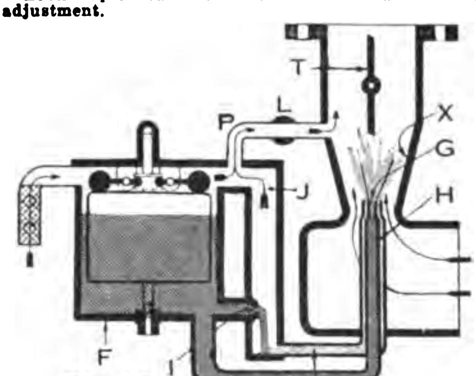


Fig. 16

An altitude adjustment is incorporated in this Zenith airplane type carburetor. The purpose of which is to adjust the gasoline supply to the changed conditions met with at higher altitudes.

If a carburetor is adjusted to deliver a properly proportioned mixture at sea level, it will supply an increasingly "rich" one as the machine mounts to higher altitudes. due to the fact that the air is lighter and less dense—as explained on page 920.

The principle of the altitude adjustment, shown in fig. 16, is as follows: The float chamber is open to the air through two screened air inlets.

The well (J) is in open communication at its top with the float chamber.

A passage (P) is provided from the float chamber to the carbureting chamber below the throttle valve; this passage is fitted with a stop cock (L), which is manually operated from the pilot's seat.

Under normal conditions, that is, on the ground, the stop cock (L) should be closed and the gasoline in the float chamber will be subjected to atmospheric pressure through the screened air inlets.

When the engine is running, the partial vacuum produced in the throat or choke (X) will draw the gasoline out of the nozzle (G) and (H) in proper proportions.

At an altitude of about 6000 feet, the aviator will begin to open the valve (L) thus drawing air from the float chamber and establishing therein a partial vacuum, which depends on the degree of opening of stop cock (L); this partial vacuum will impede the flow of gasoline through the jets, and the mixture will be made more lean.

The altitude valve should be opened as far as possible consistent with obtaining the greatest number of r. p. m. of the engine.

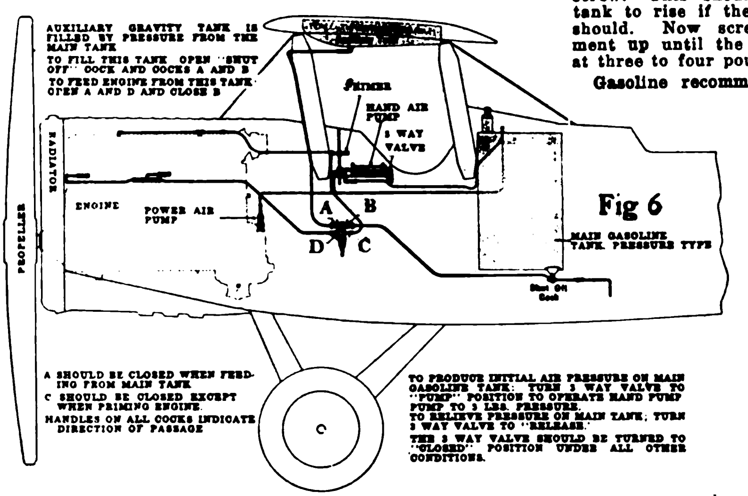
The float level is set so that gasoline level is ⅛" below main cap jets.

Gasoline System.

The air pressure feed is used from the **main gasoline tank.** The initial pressure (3 lbs.) is obtained from hand pump (fig. 6). After engine is running the air pressure is obtained from the power air pump on engine.

The auxiliary gravity feed tank, located overhead is filled by pressure from the main tank. See fig. 6, for further details.

The engine-driven air pump with its regulator, is designed to hold the pressure on the gasoline tank to approximately three pounds. In order to determine whether or not the pump is functioning properly, screw down the pressure regulator adjusting screw. This should cause the pressure in tank to rise if the pump is operating as it should. Now screw the regulator adjustment up until the pressure is held steadily at three to four pounds.



Gasoline recommended: Specific gravity; 58 to 65 Baume; initial boiling point, 102 degrees Fah., not higher than 120 degs. Fah. Final boiling point 350 degs. Fah.

Fuel consumption is .54 pounds per horse power hour, or 36 gallons per hour with wide open throttle at 1700 r. p. m.

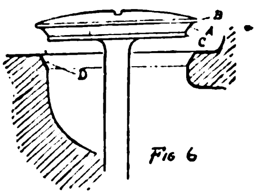
Gasoline pipe is annealed copper tubing ⅜" inside di. from tank to T, between carburetors. From this T to each carburetor, 9⁄32" di.

Air pressure pipe is 5⁄16" inside di., copper tubing.

CHART NO. 421—Carburetion and Gasoline System.

How
To Grind Valves
To Lap Scored Cylinders
To Fit Rings to Cylinders

You who drive a car, tractor, motorcycle, or operate a gas or gasoline engine whether used for a motor boat, or power plant—do you know how: to grind valves that will get the last bit of power from the engine; to lap scored cylinders, to fit a set of new rings?



This cut illustrates an interesting description of valve construction and its relation to correct grinding. Many other similar cuts in Bulletin No. 75.

This is the Clover Leaf 4-oz. Duplex can containing equal quantities of "roughing" and "finishing" grades.

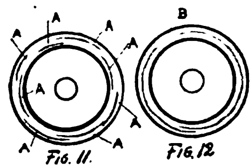
Clover Bulletins
No. 75 and No. 80

containing clear and complete illustrated directions on these vitally important subjects—sent with free samples of Clover Grinding and Lapping Compound.

Bulletin No. 75 tells of the different types of valves; how to grind valves; to tell when they're gas tight.

Bulletin No. 80 shows just how to lap scored cylinders, how to grind in piston rings, fit rings to pistons, etc.

These two bulletins are a mine of information you will be glad to get and keep.



The above cut from Bulletin No. 75 is used to illustrate a very important paragraph in Bulletin No. 75 on the subject of lines on the valve seat and how to know when they are right or wrong.

This is the pound can for shop and garage. Packed one grade to the can. Made in 7 grades 1-A (very fine). B. C. D. E. and No. 50 (very coarse). Mechanics! Try our Grade D for roughing if you want fast work.

Free Samples

With these bulletins we'll send you samples of the famous Clover Grinding and Lapping Compound. Over 10,000,000 cans of Clover have been sold—certainly proof that it possesses some merits worth investigating.

When writing, please state if you are an owner of a motor car, motorcycle, or tractor: a garage owner or mechanic; a shop or tool-room mechanic.

This concern issues two very instructive Bulletins: No. 75 on Valve Grinding and No. 80 on Lapping Scored Cylinders, Lapping in Piston Rings, Fitting Rings to Pistons, etc.

MAKE YOUR FORD A $3,000 CAR

FROM THE STANDPOINT OF MOTOR SERVICE.

Twin Ford DeLuxe Racing Cars Carrying Roof Sixteen Overhead Valve Equipment.

ROOF 16 OVERHEAD VALVE EQUIPMENT

A POWER DEVICE NEEDED BY EVERY FORD OWNER.

One hundred percent extra efficiency, with greater gasoline and oil economy, for either touring car or truck. Hill climbing for the touring car owner beyond his wildest dreams. Sand, mud, or the steepest grades have no terrors for the Ford owner with the Roof 16 valve cylinder head.

Let us double the pulling power and hauling capacity of your converted Ford with truck unit.

FORD RACING CARS

SPEED—Ford cars with our 16-valve cylinder head equipment have been rivals of the best racing cars on mile and half mile tracks, and have practically driven the high priced racing cars from competition, excepting on Speedways. Ben Lawell, of the Fielding Auto Racing Team, Toledo, Ohio, who has attained a speed of over 100 miles per hour; Joseph C. Hayes, of San Francisco, with a record of 97 miles per hour, and hundreds of others with phenomenal speed records, attest the wonderful power given to a Ford car, by the use of the Roof 16 overhead valve equipment.

We are headquarters for everything necessary in Ford speed equipment, including polished nickel Roof 16 overhead valve equipment, Aluminite and Triple Lite pistons and rings, gay iron pistons and rings complete, Aluminite connecting rods, parts for underslinging chassis nickel steel racing gears three to one ratio, racing carburetors, everything in ignition equipment, counter-balance for crankshafts, high speed camshafts, wire wheels and steering gears.

Tell us what you want. We can supply it. Send for photographs of our beautiful racing bodies and racing radiators, which are our own special design.

DEALERS—GARAGEMEN—REPAIRMEN

The ROOF-PEUGEOT TYPE CYLINDER HEAD FOR FORDS IS AN ALL-YEAR SELLER. THEY ARE QUICKLY AND EASILY INSTALLED—SET RIGHT IN PLACE OF THE OLD CYLINDER HEAD. ROCKER ARMS OPERATE FROM THE REGULAR CAMSHAFT. Every Ford owner is a likely prospect, every Ford truck owner is a SURE SALE. If you want a steady stream of business throughout the year that pays, get our agency terms. Send for free illustrated literature of the greatest selling specialty for 1919. Place one equipment in your territory and it will bring every Ford owner to your door.

SEND FOR OUR SPECIAL TIRE CIRCULAR.

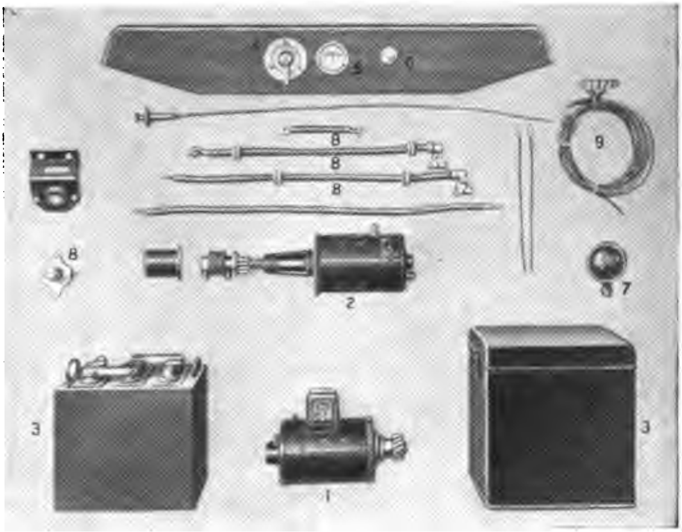
ATWATER KENT STARTING AND LIGHTING SYSTEM
for
FORD Touring Cars and Roadsters (1919 only)



CONSISTING OF:

1—Generator with cut-out, fuse and driving gear.

2—Starting motor with Bendix drive and housing.

3—Exide, 80 amp. hr. battery and box.

4—Combination lighting and ignition switch.

5—Instrument board and ammeter.

6—Carburetor choke lever, extra heavy.

7—Electric tail lamp and bulb.

8—Starting switch and starting cables.

9—Lighting wires.

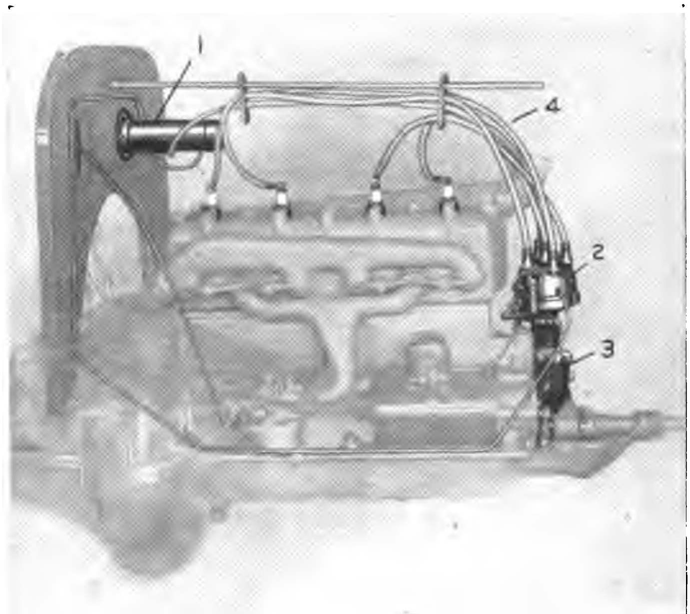
10—Bolts, screws, nuts, washers and staples.

11—Carefully prepared instructions for installation.

SYSTEM, COMPLETE AS ABOVE.......... **$97**

The outfit comes to the purchaser absolutely complete from the tail light and bulb to the smallest screw necessary for the installation. The price, NINETY-SEVEN DOLLARS COMPLETE, includes every item which is used in making the installation. THERE ARE ABSOLUTELY NO EXTRAS OF ANY SORT TO BUY.

Type CA—ATWATER KENT IGNITION—Type CA
for
FORD Cars with Electric Starting and Lighting 1919 and later Models only



CONSISTING OF:

1—Atwater Kent Coil.

2—Atwater Kent Timer Distributor, with Automatic and also Manual Spark Control.

3—Bracket and Parts to Attach.

4—Cables.

SYSTEM, COMPLETE AS ABOVE......... **$24**

Atwater Kent Mnfg. Co., 4937 Stenton Ave., Philadelphia, Pa.

Type for Public Garage.

Tungar

BATTERY CHARGER

An Ideal Battery Charger for Alternating Current

The 6 amp., 75 volt Tungar Rectifier will charge any combination of 3, 4, 5, 6 up to 30 cells at 6 or 7 amperes or less from alternating current.

This is a practical device demonstrated by actual service, it equips the garage for efficient battery charging at a much lower cost than any other reliable device of similar capacity.

Attached to the wall, the Tungar takes up no floor space. It uses alternating current at a cost of but six cents an hour for ten 3-cell batteries. It is self-starting, requiring no attendant

The smaller outfits (5/3 amp. 7.5/15 volts and 2 amp. 7.5 volts) are designed for battery charging in the private garage. These outfits have the same advantages as the larger set.

The following bulletins give full information:

Booklet B-3487. For the large outfit.
Booklet B-3532. For the private garage set,
Booklet B-3529. Four battery type.

Type for Private Garage

WRITE TODAY—NOW—FOR

Free Illustrated Catalog on Dyke's Home Study Course

IT MAY MEAN A GREAT DEAL TO YOU IN THE FUTURE

LET US SHOW YOU pictures of shops and cars of students who are now engaged in business—who actually got their start through the Dyke Course—we will show you a HUNDRED or more of testimonials, if you write us.

Dyke's Correspondence School of Motoring,
Granite Building, St. Louis, Mo.

Gentlemen:—

Mail me your FREE printed matter explaining your Course of Automobile Engineering.

NAME ....

CITY ....

STREET .... STATE ....

NOTE—State if you now have the Encyclopedia and Models, or Encyclopedia alone.
(If you have Encyclopedia, be sure and state what Edition you have.) (12-2nd)

A Few of the Many Testimonials.

First thought he could not learn by mail: Have just overhauled a car and had great success. People said a person could not learn by mail, and I will admit that it did have me guessing when I first read your ad, but I am now convinced. The working Models and the Charts, and particularly the examinations, make it easier to learn by your system than any other way.—E. A. Tucker, Charlotte, Mich.

Now running a repair shop: Mr. W. O. Johnson, Jr., of Spartansburg, Pa., is now operating a repair shop and supply store. He learned from Dyke's Course.

Learned more from course than in shop: To say that I am pleased with your Course is putting it mildly. Before buying it, I investigated five or six others, varying in price from $25 to $55. One of the concerns claimed they had models; but I remember seeing in your printed matter, that you were the inventor and patentee of the New Model Idea, so I insisted on their proving that they had models, which they could not do. The other schools seemed to be unwilling to give very much detail as to what their Course consisted of. I am glad to say, that instead of misrepresenting your Course, I find it even better than you claim. I have worked in two different garages, but have learned many things from your Course that I could not have learned in the shop. Your treatment of the ignition and other subjects is very clear indeed. Wilfred S. Baker, 129 State Street, Bristol, Rhode Island. Enrollment No. 6755.

More work than he can handle: Since taking your Course I have had all the work I can handle in overhauling engines and making adjustments. —O. A. Arnett, Woodland, Mich. Enrollment No. 8661.

I send you this letter to use to tell others: I do this because you have helped me and I want to now help you. After completing Course, I secured employment in a garage at a good salary. I have overhauled cars and have a good job the year round in the P. T. Legare Auto Garage.—George Gaudreau, 110 Massue Street, Quebec, Canada.

Leading Authorities of the Motoring World Recommend Dyke's Home Study Course.

Barney Oldfield, Chas. Duryea, Lord Montagu of England and many others. Write us for our catalog and read what they say.

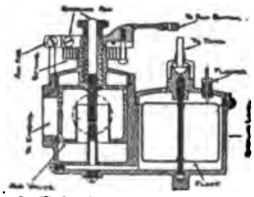
Some Firsts in America—By A. L. Dyke.

The first practical automobile book published in America was published by A. L. Dyke. The small book, illustration of which is shown, was originally prepared in 1899 and 1900. It was revised in 1908.

In the issue of Motor Age, Oct. 29, 1903 a part of the article reads; "The A. L. Dyke Co., published the first practical automobile work intended solely for the automobile user."

Illustration of the first practical automobile book published in America.

The first automobile supply business in America was originated by A. L. Dyke. In issue of Motor Vehicle Review, published in Cleveland, Ohio, 1900, now "The Automobile" of New York, part of the article reads: "Mr. Dyke originally started in the automobile supply business, the first in America in 1897." The Automobile Review of Chicago, issue of April 1900 states; "Very early in the industry Mr. Dyke saw there would be a demand for Auto Supplies, parts, etc. and organized and incorporated The St. Louis Automobile and Supply Co."



DYKE'S FLOAT TYPE CARBURETOR

Illustration of the original drawing of the first constant level type carburetor placed on the American market.

The first float feed carburetor manufactured and placed on the American market was advertised and marketed by A. L. Dyke in 1900. At that time the few automobile manufacturers were using mixing valves.

NOTE—We advise one to take a Practical Course if possible—at a good school—but don't think for a moment you are going to learn without studying—go to a school where books are used

HOYT ELECTRICAL TESTING INSTRUMENTS

Hoyt Rotary Meter.

A combined volt-ammeter reading 5 different ranges: 0-30 amperes; 0-3 amperes; **0-90** mil-volts; 0-30 volts; 0-3 volts.

It will locate grounds, short-circuits, open-circuits, poor connections; **field and armature** troubles and **battery difficulties.**

It will determine the output of **a generator;** tell you how much current the **starting motor** takes (in connection with a 300 to 500 ampere shunt); the rate at which battery is discharging; the current consumption of each **individual lamp, or all lamps;** voltage of storage battery, or each individual cell etc.

Hoyt Standard Rotary Meter.

Price complete with a 32 page booklet of instructions, fully illustrated, entitled "Hunting Down Electrical Troubles"...... **$18.00**

Shunts to be used with this instrument can be purchased separately. **Price** 100 ampere shunt $4; 200 ampere $4.50; 300 ampere $5; 400 ampere $5.50; 500 ampere $6. See page 414 for explanation of shunts.

The knowledge you will gain on how to make electrical tests will be worth the price of the meter to say nothing of the profit you can make with a meter of this kind.

Hoyt Cadmium Voltmeter.

If you propose doing storage battery work you will also need this instrument.

The purpose of the cadmium test is explained on page 864I.

Type 515D Cadmium Voltmeter. Reads: .3-0-2.7 volts. The .3 reading is to the left of 0 and 2.7 to right of 0.

Fig. 15—explains how to test a battery cell with the Hoyt cadmium voltmeter. When testing, the normal charging current must be passing through battery. The cadmium stick is introduced into the electrolyte of one cell, which really makes of the cell, two distinct cells. The steel metal prod is on the positive cell terminal and the cadmium stick is connected to the negative terminal of the voltmeter, which is really making the negative plate. With these connections, the voltage of the positive plates is being measured.

When the metal prod is on the negative cell terminal, the voltage of the **negative plates** is being measured.

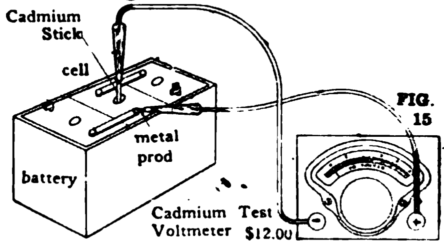

FIG. 15

Keeping these points in mind, the table below will be clear. **These figures represent** average readings of many experiments, although readings may vary slightly.

Condition of Cell	Voltage of Positive Plates	Voltage of Negative Plates	Net Voltage of Cell
Charged	+2.4	—0.1	+2.5
Discharged	+2.05	+0.25	+1.8

Note that the net voltage of the cell is the algebraic difference between the voltage of positive plates and that of negative, plus readings being to the right of zero and minus to the left.

The proof of the test is in discovering if the voltage of the positive plates minus that of the negative plates equals the net voltage of the cell, when measuring directly across the terminals. If this condition does **not exist, the plates are certainly in bad shape** and comparison with the table here published will show in general which plates are at fault. The only remedy is to open up the cell and repair it.

Price of cadmium voltmeter **$12.00**
Price of cadmium stick, prod and cables **3.50**

Hoyt High Rate Cell Tester.

The particular value of this device is to be able to compare readings of one cell with another, in the same battery. The prods (P) are placed on the cell terminals. The terminals (T) are connected with a voltmeter reading 8 volts (The Hoyt Rotary meter is shown connected in this instance). The resistance (R) is such that a current of 100 amperes passing through will show a voltage drop of 1 volt.

When testing cells, if no reading is indicated then that cell is in bad condition. If readings should be alike at first and then drop appreciably, the indication is that cell is short-circuited internally, or plates are not in good condition. In case of poor plates, the drop is greater than with short-circuits.

Price of Cell Tester (without meter).......$5.00
